NAPOLEON I *TO* OZONOLYSIS

NAPOLEON I (1769–1821), emperor of the French from 1804 to 1814 and again for "the Hundred Days" in 1815, was born at Ajaccio in Corsica on Aug. 15, 1769, one year and three months after the cession of Corsica to France by the Genoese. He was the fourth child—and the second to survive infancy—of Carlo Buonaparte and his wife Letizia Ramolino (*see* BONAPARTE). His father's family was of ancient nobility. Tuscan in origin, it had emigrated to Corsica in the 16th century: Napoleon himself in his last years scoffed at the genealogy that flatterers and courtiers had concocted to make him descend from the 12th-century Buonapartes of Treviso and Bologna, whose line was extinct. In any case, Carlo Buonaparte was one of the delegates sent to Paris by the Corsican nobility.

A lawyer by profession, Carlo Buonaparte had married the beautiful and strong-willed Letizia Ramolino when she was only 14 years old; and they eventually had eight children to bring up in very difficult times. The French occupation of Corsica was resisted by a number of the inhabitants, led by Pasquale Paoli, and Carlo Buonaparte joined Paoli's party, taking his wife and family away with him lest the French should seize them as hostages. When Paoli had to flee, however, Carlo Buonaparte came to terms with the French. Winning the protection of the governor of Corsica, he was appointed assessor for the judicial district of Ajaccio in 1771. In 1778, moreover, through the influence of the governor's brother, he obtained the admission of his two eldest sons, Joseph and Napoleon, to the Collège d'Autun, to which he took them in Dec. 1778.

These events serve partly to explain Napoleon's character. A Corsican by birth, heredity and childhood associations, he continued for some time after his arrival in "continental" France to regard himself a foreigner; yet from the age of nine he was educated in France as other Frenchmen were, according to French methods and ideas. While Stendhal's tendency to account for Napoleon entirely in terms of his Tuscan and Corsican origins and to see in him a reincarnation of some 14th-century Italian *condottiere* is an overemphasis on one aspect of his character, it must be remembered that Napoleon shared neither the traditions nor prejudices of his new country: remaining a Corsican in temperament, he was first and foremost, through the education he received and the books that he read, a man of the 18th century.

Napoleon received his education at three schools: at Autun, where he stayed only three months; at the military college of Brienne, where he attended for five years; and finally at the military academy in Paris, where his studies lasted only one year. It was during Napoleon's year in Paris that his father died at Montpellier—where he had gone for treatment of a stomach cancer—on Feb. 24, 1785, leaving his family in straitened circumstances. Napoleon, although not the eldest son, wanted to do all that he could to help his mother, and at the age of 16 he was acting as the head of the family. On Sept. 1, 1785, he completed his studies at the military academy in Paris, where he ranked 42nd in a class of 51. He was made second lieutenant of artillery in the regiment of La Fère, then garrisoned at Valence.

The regiment of La Fère was a kind of training school for young artillery officers. Napoleon continued his education there, reading much, in particular the fashionable works on strategy and tactics by such writers as the comte J. A. H. de Guibert. He also wrote his own *Lettres sur la Corse,* in which he reveals his feeling for his native island. He went back to Corsica in Sept. 1786 and did not rejoin his regiment, then in barracks at Auxerre, until June 15, 1788. By that time the agitation that was to culminate in the French Revolution had already begun. A reader of Voltaire and of Rousseau, Napoleon believed that a political change was indispensable; but he seems not to have seen any need for radical social reforms, as his environment would not have brought him into contact with the labouring population.

THE REVOLUTIONARY PERIOD, 1789–99

In 1789 the Constituent Assembly (*see* FRANCE: *History;* FRENCH REVOLUTION) allowed Paoli to return to Corsica. As soon as Napoleon learned of this, he asked for leave to join him and obtained it in September. He joined Paoli's group with enthusiasm, but Paoli had no sympathy for the young man, whom he considered to be a "foreigner." Disappointed, Napoleon returned to France in Feb. 1791. On April 1 he was appointed first lieutenant to the 4th regiment of artillery, garrisoned at Valence. He at once joined the Jacobin club there and soon became its president, making speeches against nobles, monks and bishops. On Sept. 2, 1791, he got leave to go back to Corsica again for three

months. He was elected lieutenant colonel in the national guard, but he fell out completely with Paoli, its commander in chief. Corsican political quarrels made him forget the date when his leave expired, and on Jan. 1, 1792, he was listed as a deserter. In April France declared war against Austria (*see* FRENCH REVOLUTIONARY WARS) and his offense was forgiven. Going to Paris in May, Napoleon was an indignant witness of the attack on the royal palace of the Tuileries on June 20. He also saw the insurrection of Aug. 10, but attributed its success to Louis XVI's incompetence.

Napoleon was promoted to the rank of captain but did not rejoin his regiment, returning instead to Corsica on Oct. 10, 1792, on the pretext of escorting his sister Élisa home. Paoli was now exercising dictatorial powers on the island and preparing to separate Corsica from France. Napoleon joined the Corsican Jacobins who opposed this policy: he wanted Corsica to be involved with France in the coming struggle. On Feb. 23, 1793, he occupied the little island of San Stefano, belonging to the kingdom of Sardinia-Piedmont (at war with France since September). Paoli ordered the evacuation of this island, but the Convention in Paris decided on the arrest of Paoli, and civil war broke out in Corsica (April 1793). Paoli had the Buonaparte family condemned to "perpetual execration and infamy," whereupon they all fled to France (June).

Toulon (1793).—Napoleon Bonaparte, as he may henceforth be called (though the family did not drop the spelling Buonaparte till after 1796), rejoined his regiment at Nice. He was given the task of collecting supplies of munitions in the Rhone valley for the army of Italy. During this mission he witnessed the struggles at Marseilles and at Avignon between the Jacobin supporters of the Convention and the "federalists" who, with royalist backing, were against it. In his *Souper de Beaucaire,* written at this time, he argued vigorously for united action by all republicans rallied round the Jacobins and the Convention. At the end of Aug. 1793 the Convention's troops under J. F. Carteaux (a former painter) had taken Marseilles but were halted before Toulon, where the royalists had called in British forces. As the commander of the Convention's artillery had been wounded, the commissioner to the army, A. C. Saliceti, a Corsican deputy and a friend of Napoleon's family, got the post for Bonaparte (Sept. 17); and Bonaparte was promoted *chef de bataillon* on Sept. 29 and adjutant general, head of brigade, on Oct. 7. His relations with Carteaux were not cordial, but he was soon on better terms with Carteaux's successors, A. Doppet and, in particular, J. F. Dugommier, who took command of the army on Nov. 16. Thenceforward Bonaparte could take active charge of the bombardment of the British positions. He received a bayonet wound on Dec. 16. On Dec. 17 the British troops, harassed by Bonaparte's artillery, evacuated Toulon; on Dec. 19 the French entered the town; and on Dec. 22 Bonaparte was promoted brigadier general in recognition of his decisive part in the capture of the town. Augustin Robespierre, the commissioner to the army, wrote to his brother Maximilien praising the "transcendent merit" of the young republican officer. On Feb. 7, 1794, Bonaparte was appointed commandant of the artillery in the army of Italy. He took part in the operations round Nice.

The Thermidorian Interval (1794–95).—Robespierre fell from power in Paris on 9 Thermidor (*i.e.,* July 27, 1794). When the news reached Nice, the *représentants en mission* to the army, regarding Bonaparte as a protégé of Robespierre's, had him arrested on a charge of conspiracy and treason (Aug. 6). He was freed on Sept. 14 but was not restored to his command. In March 1795 he was offered the command of the artillery in the army of the West, but he refused this post, which seemed to hold no future for him, and went to Paris to justify himself. Life was difficult for him on half pay, though he was carrying on an affair with Désirée Clary, daughter of a rich Marseilles businessman and sister of the Julie Clary who had just married his elder brother Joseph. Yet he was unable to obtain a satisfactory command, as he was feared for his intense ambition and for his relations with the "Montagnards" (the more radical members of the Convention). He then considered offering his services to Turkey.

The Coup of Vendémiaire.—Bonaparte was still in Paris in 1795 when the Convention, on the eve of its dispersal, submitted the new Constitution of the Year III to a referendum, together with decrees according to which two-thirds of the members of the Convention were to be re-elected to the new legislative assemblies. The royalists, hoping that they would soon be able to restore the monarchy, rose in revolt to prevent these measures from being put into effect. Barras, entrusted with full powers by the Convention, was unwilling to rely on the existing commander of the troops of the interior, Gen. J. F. de Menou, a weak man suspected of dealings with the royalists. He therefore had Bonaparte appointed second-in-command, as he knew of his services at Toulon and of his present lack of employment in Paris. Thus it was Napoleon who directed the defense, positioned the artillery and shot down the columns of rebels who were marching against the Convention (13 Vendémiaire, Year IV; Oct. 5, 1795). Having saved the Convention and the republic, he was derisively called "Général Vendémiaire" by his opponents.

After the rising of Vendémiaire, Bonaparte kept his place as commander of the army of the interior. Consequently he was henceforth aware of every political development in France. He also became the respected adviser on military matters to the new government, the Directory. Lastly, he came to know an attractive Creole, Joséphine Tascher de La Pagerie, the widow of Gen. Alexandre de Beauharnais (guillotined during the Terror), the mother of two children and a woman of many love affairs.

The Italian Campaign of 1796–97.—From every point of view, a new life was opening for Bonaparte. He began to observe the activities of the left-wing group directed by François Babeuf and by an Italian whom he had known in Corsica, P. M. Buonarroti. This group, which met at the Panthéon, wanted a new revolution to install a communist regime. On the instructions of the Directory, Bonaparte closed the Panthéon club (Feb. 28, 1796). Having thus proved his loyalty to the regime, he was appointed commander in chief of the army of Italy (March 2), a post that

he had been soliciting for several weeks so that he could personally conduct part of the plan of campaign adopted by the Directory on his advice. He married Joséphine on March 9 and left for the army two days later.

Arriving at his headquarters at Savona, Bonaparte found that his army, which on paper consisted of 43,000 men, in fact numbered scarcely 30,000 men available for service; and even these were ill-fed, ill-paid, ill-equipped and ill-shod. On March 28, 1796, he made his first proclamation to his troops: "Soldiers, you are naked, badly fed. . . . Rich provinces and great towns will be in your power, and in them you will find honour, glory, wealth. Soldiers of Italy, will you be wanting in courage and steadfastness?" He took the offensive on April 12 and, after the victories of Montenotte, Dego, Millesimo and Mondovi, defeated successively the Austrian and the Sardinian armies, separated them and marched on Turin. King Victor Amadeus III of Sardinia asked for an armistice, which was signed at Cherasco on April 28 and converted into a peace treaty in Paris on May 15: Nice and Savoy, which had been occupied by the French since 1792, were annexed to France. Bonaparte went on against the Austrians and occupied Milan, but was held up at Mantua. While his army was besieging this great fortress, he signed armistices with Ferdinand, duke of Parma, on May 9, with Ercole III, duke of Modena, on May 17, and finally with Pope Pius VI on June 23.

At the same time Bonaparte took an interest in the political organization of Italy. A plan for the "republicanization" of Italy by a group of Italian "patriots" led by Buonarroti had to be shelved when Buonarroti was arrested for complicity in Babeuf's conspiracy against the Directory. Thereafter Napoleon, without discarding the Italian "patriots" altogether, restricted their freedom of action. He set up a republican regime in Lombardy, but kept a close watch on its leaders; and in Oct. 1796 he created the Cispadane republic by merging Modena and Reggio nell'Emilia with the papal states occupied by the French army (that is to say, Bologna and Ferrara). Finally he sent an expedition from Livorno to recover Corsica, which the British had evacuated.

Austrian armies advanced four times from the Alps to relieve Mantua. Each time Napoleon defeated them—not always without risk to his own army. After the last Austrian defeat, at Rivoli (Jan. 14, 1797), Mantua capitulated. Bonaparte then forced the pope to sign peace at Tolentino (Feb. 19). Next, at the head of all his forces, he marched on Vienna. He was about 60 mi. from that capital when the Austrians sued for an armistice. By the preliminaries of peace, signed at Leoben on April 18, Austria ceded the southern Netherlands to France and recognized the Lombard republic, but received in exchange some territory that had belonged to the old republic of Venice, which was partitioned between Austria, France and Lombardy. In the six months preceding the final conclusion of peace Napoleon concerned himself mainly with political problems. The Lombard and Cispadane republics, with the Valtellina and some of the formerly Venetian territory, were united to form the Cisalpine republic; the republic of Genoa was reorganized on democratic principles as the Ligurian republic; and Jacobin propaganda was encouraged in Venetia. Some Italian patriots hoped that these developments would soon lead to the formation of a single and indivisible "Italian republic," modeled on the French.

The Coup of Fructidor and Campo Formio.—Meanwhile Bonaparte was also watching events in France. He was uneasy at the successes of the royalists in the elections in the spring of 1797 and advised the Directory to oppose them, if necessary, by force. When an attempted *coup d'état* by the Directory against the royalists failed (July 1797), Bonaparte made his army vote "addresses" hostile to the royalists and sent Pierre Augereau, one of his generals, to Paris, together with several officers and men "on leave." Augereau's successful *coup d'état* of 18 Fructidor (Sept. 4, 1797) eliminated the royalists' friends from the government and from the legislative councils and enhanced Bonaparte's prestige. Thus Bonaparte could conclude the peace treaty of Campo Formio with Austria as he thought best (Oct. 17). The Directory was displeased by this treaty because it ceded Venice to the Austrians and did not secure the left bank of the Rhine for France; but it raised Bonaparte's popularity to its peak, as he had restored peace on the continent after five years of war.

The Egyptian Campaign (1798–99).—The war at sea, against the British, continued. The directors, who wanted to launch an invasion of the British Isles, naturally appointed Bonaparte to command the army assembled for this purpose along the Channel. After a rapid inspection (Feb. 1798) he announced that the operation could not be undertaken until France had command of the sea. Instead he suggested that France should strike at the sources of Great Britain's wealth by occupying Egypt and threatening the route to India. This proposal, seconded by Talleyrand, the minister for foreign affairs, was accepted by the directors, who were glad to get rid of their ambitious young general.

The expedition, thanks to some fortunate coincidences, was at first a great success: Malta, the great fortress of the Knights Hospitalers of St. John of Jerusalem, was occupied on June 10, 1798, Alexandria taken by storm on July 1, and all the delta of the Nile rapidly overrun. On Aug. 1, however, the French squadron at anchor in Aboukir bay was completely destroyed by Adm. Horatio Nelson's fleet in the battle of the Nile, so that Napoleon found himself confined to the land that he had conquered. He proceeded to establish western political institutions, administration and technical skills in Egypt; but Turkey, nominally suzerain over Egypt, declared war on France in September. To prevent a Turkish invasion of Egypt and also perhaps to attempt a return to France by way of Anatolia, Bonaparte marched into Syria (Palestine) in Feb. 1799. His progress northwest was halted at Acre, where the British admiral Sir William Sidney Smith and the French émigré A. Le Picard de Phélippeaux (who had been at Brienne with Napoleon) withstood a siege. In May 1799 Bonaparte began a disastrous retreat to Egypt.

The Coup of Brumaire.—The battle of the Nile showed to Europe that Bonaparte was not invincible, and Great Britain, Austria, Russia and Turkey formed a new coalition against France. The French armies in Italy were defeated in the spring of 1799 and had to abandon the greater part of the peninsula. These defeats led to disturbances in France itself. The *coup d'état* of 30 Prairial (June 18, 1799) expelled the men of moderate views from the Directory and brought into it men who were considered Jacobins. Yet the situation remained confused, and one of the new directors, Emmanuel Sieyès, was convinced that only military dictatorship could prevent a restoration of the monarchy: "I am looking for a sabre," he said. In the hope of demoralizing the French army in Egypt, Admiral Smith had the newspapers recording these events passed to Bonaparte. The latter did not take long to make up his mind: he would leave his army and return to France—in order to save the republic, of course, but also to take advantage of the new circumstances and to seize power. The Directory had in fact ordered his return, but he had not received the order, so that it was actually in disregard of his instructions that he left Egypt with a few companions on Aug. 22, 1799. Their two frigates tacked along the African coast and miraculously escaped interception by the British. Bonaparte landed at Fréjus on Oct. 9 and was in Paris on Oct. 14.

By this time André Masséna's victories in Switzerland and Guillaume Brune's in Holland (Sept.–Oct. 1799) had averted the danger of invasion, and the counterrevolutionary risings within France had more or less failed. A *coup d'état* could therefore no longer be justified by the need to save the republic. Sieyès, however, had not given up his projects, and now he had his "sabre." From the end of October he and Bonaparte were in league together planning the *coup d'état*, and on 18–19 Brumaire, Year VIII (Nov. 9–10, 1799), it was carried out: the directors were forced to resign, the members of the legislative councils were dispersed, and a new government, the consulate, was set up. The three consuls were Bonaparte and two of the directors who had resigned, Sieyès and Roger-Ducos. Henceforth Bonaparte was the master of France.

THE CONSULATE, 1799–1804

Bonaparte, now 30 years old, was thin, short and wore his hair cut close—the *petit tondu*, or "little crop-head," as he was called. Not much was known about his personality, but people had con-

fidence in a man who had always been victorious (the Nile and Acre were forgotten) and who had managed in 1797 to negotiate a brilliant treaty. He was expected to bring peace back, to end disorder and to consolidate the political and social "conquests" of the Revolution. He was indeed exceptionally intelligent, prompt to make decisions and indefatigably hardworking, but also insatiably ambitious, always pursuing greater and greater enterprises. He seemed to be the man of the Revolution because it was thanks to the Revolution that he had climbed, at so early an age, to the highest place in the state. He was not to forget it: but more than a man of the Revolution he was a man of the 18th century, the most enlightened of the enlightened despots, a true son of Voltaire. He did not believe in the sovereignty of the people, in the popular will, or in parliamentary debate. Yet he put his confidence more in reasoning than in reason and may be said to have preferred "men of talent"—mathematicians, jurists and statesmen, for instance, however cynical or mercenary they might be—to "technicians" in the true sense of the word. He believed that an enlightened and firm will could do anything if it had the support of bayonets; he despised and feared the masses; and, as for public opinion, he considered that he could mould and direct it as he pleased. He has been called the most "civilian" of generals, but essentially he never ceased to be a soldier: clothes and titles could make no difference.

The Constitution of the Year VIII.—Bonaparte imposed a military dictatorship on France, but its true character was at first disguised by the Constitution of the Year VIII (4 Nivôse; Dec. 25, 1799), drawn up by Sieyès. This constitution did not guarantee the "rights of man" or make any mention of "liberty, equality and fraternity," but it did reassure the partisans of the Revolution by proclaiming the irrevocability of the sale of national property and by upholding the legislation against the *émigrés*. It gave immense powers to the first consul, leaving only a nominal role to his two colleagues. The first consul, namely Bonaparte, was to appoint ministers, generals, civil servants, magistrates and the members of the *conseil d'état* and even had an overwhelming influence in the choice of members for the three legislative assemblies, the senate, the *corps législatif* and the tribunate, though these members were theoretically to be chosen by universal suffrage. Submitted to a plebiscite, the constitution won an overwhelming majority (Feb. 1800). It is true that the vote was not taken by secret ballot and that pressure was exerted in many ways, but it appeared that Bonaparte was brought to power by a vote of more than 3,000,000 against about 1,500.

The Administration.—The consulate's work of administrative reform, undertaken at Bonaparte's instigation, was to be more lasting than the constitution and so more important for France. At the head of the government was the *conseil d'état,* created by the first consul and often effectively presided over by him; it was to play an important part both as the source of the new legislation and as an administrative tribunal. At the head of the administration of the *départements* were the prefects, who carried on the tradition of the intendants of the *ancien régime,* supervising the application of the laws and acting as the instruments of centralization. The judicial system was profoundly changed: whereas hitherto, from the beginning of the Revolution, judges had been elected, henceforth magistrates were to be nominated by the government, their independence however being assured by their irremovability from office. The police organization was greatly strengthened. The financial administration was considerably improved: instead of the municipalities, special functionaries were entrusted with the collecting of direct taxes; the franc was stabilized (*franc de Germinal*); and the Banque de France was created. Education was transformed into a major public service; secondary education was given a semi-military organization, and the university faculties were re-established. Primary education, however, was still neglected.

The Concordat.—Bonaparte shared Voltaire's belief that the people needed a religion. Personally, he was indifferent to religion: in Egypt he had said that he wanted to become a Muslim. Yet he considered that religious peace had to be restored to France. As early as 1796, when he was concluding the armistice in Italy with Pope Pius VI, he had tried to persuade the pope to retract his briefs against the French priests who had accepted the Civil Constitution of the Clergy. Pius VII, who succeeded Pius VI in March 1800, was more accommodating than his predecessor, and negotiations were opened with him in September. Ten months later a concordat was signed reconciling the Church and the Revolution. The pope recognized the French republic and called for the resignation of all former bishops; new prelates were to be designated by the first consul and instituted by the pope; and the sale of the property of the clergy was officially recognized by Rome. The concordat in fact admitted freedom of worship and the lay character of the state. In order, however, to induce the numerous ex-revolutionaries in the government to accept the concordat, the first consul appended to it the "Organic articles," which stipulated that papal acts should not be published in France or catechisms drawn up without the state's authorization.

The Code.—The codification of the civil law, first undertaken in 1790, was at last completed under the consulate. The code promulgated on March 21, 1804, and later known as the Code Napoléon (*q.v.*), gave permanent form to the great gains of the Revolution, individual liberty, freedom of work, freedom of conscience, the lay character of the state and equality before the law; but at the same time it protected landed property, gave greater liberty to employers and showed little concern for employees. It granted only limited legal rights to women, but maintained divorce.

Military Organization.—The army received the most careful attention. The first consul retained in outline the system instituted by the Revolution: recruitment by forced conscription, but with the possibility of replacement by substitutes; the mixing of the conscripts with old soldiers; and the eligibility of all for promotion to the highest ranks. Nevertheless the creation of the academy of St. Cyr, to produce infantry officers, made it easier for the sons of bourgeois families to pursue a military career. Moreover, the École Polytechnique, founded by the Convention, was militarized in order to provide officers for the artillery and engineers. Yet Bonaparte was not concerned about introducing new technical inventions into his army: he stopped the construction of military balloons, which had been started in 1793; and he sent home the American engineer Robert Fulton, who had come to suggest a steamship and a submarine for the French fleet. To win his battles he put his trust in the "legs of his soldiers": his basic strategic idea was a fast-moving army.

The Campaign of Marengo and the Peace of Lunéville (1800–01).—The first consul spent the winter and spring of 1799–1800 reorganizing the army and preparing for an attack on Austria (Russia had become estranged from the coalition against France). With his usual quick assessment of the situation he saw the strategic importance of Switzerland, from which he would be free to outflank the Austrian armies either in Germany or in Italy as he might see fit. His past successes made him choose Italy. Taking his army across the Great St. Bernard pass before the snow had melted, he appeared unexpectedly behind the Austrian army which was besieging Genoa. The battle of Marengo (June 14, 1800) gave the French command of the Po valley as far as the Adige; and in December another French army, led by Moreau, defeated the Austrians at Hohenlinden in Germany. Austria was forced to sign the peace of Lunéville on Feb. 9, 1801, whereby France's right to the "natural frontiers" which Julius Caesar had given to Gaul, namely the Rhine, the Alps and the Pyrenees, was recognized.

The Peace of Amiens (1802).—Great Britain alone remained at war with France. Bonaparte again began to prepare an invasion, as in 1798, but without great conviction. He preferred to stimulate Russian animosity against Great Britain and had persuaded the Russian emperor Paul I to form a "League of Armed Neutrality" with Sweden, Denmark and Prussia (Dec. 1800). The assassination of Paul in March 1801 and Nelson's bombardment of Copenhagen ruined this calculation, but Great Britain was tired of the struggle, and William Pitt, the prime minister, had already resigned. Preliminaries of peace, concluded in London on Oct. 1, 1801, put an end to hostilities and peace was signed at Amiens on March 25, 1802.

The Life Consulate.—General peace was re-established in

MANSELL COLLECTION, LONDON

"BONAPARTE CROSSING MONT SAINT BERNARD," BY JACQUES LOUIS DAVID, 1800. IN THE MUSÉE DE VERSAILLES

Europe for the first time in ten years. The first consul's prestige increased still more; and his friends—at his suggestion—proposed that a "token of national gratitude" should be offered to him. In May 1802 it was decided that the French people should give their opinion through a referendum, under the same conditions as in 1800, on the following question: "Shall Napoleon Bonaparte be consul for life?" In August an overwhelming majority of 3,500,000 votes against less than 10,000 granted him the prolongation of his consulate; and he also received the right to designate his successor.

The Failure of the General Pacification.—Bonaparte's conception of international peace did not coincide with that of the British government. For the British the terms of the treaty of Amiens represented an absolute limit beyond which they could under no circumstances agree to go: they even hoped, when they got the chance, to take back some of the concessions they had been forced to make. For Napoleon Bonaparte, on the other hand, the treaty of Amiens marked the starting point for a new French ascendancy. First of all, from the economic point of view, he meant to reserve half of Europe as a market for France and, to the indignation of British merchants, refused to lower customs duties. Then, from the naval point of view, he intended to revive France's expansion overseas, to recover San Domingo (which had rebelled), to occupy Louisiana (ceded to France by Spain in 1800), perhaps to reconquer Egypt and at any rate to extend French influence in the Mediterranean, in the Levant and in the Indian ocean. Finally, on the continent of Europe, he advanced beyond France's natural frontiers, incorporating Piedmont in France, intervening in Switzerland to restore order and taking a hand in the affairs of Germany, where princes dispossessed of territory on the Rhine under the peace of Lunéville were to be compensated with shares of the secularized ecclesiastical states.

Great Britain was alarmed by this expansion of France in peacetime and found it scarcely tolerable that one state should possess all the coastline of the continent from Genoa to Antwerp. However, the immediate occasion of Franco-British rupture was the problem of Malta. According to the treaty of Amiens, the British, who had taken the island on the collapse of the French occupation, should have restored it to the Knights Hospitalers; but the British, on the pretext that the French had not yet evacuated certain Neapolitan ports, refused to leave the island. Franco-British relations became strained, and in May 1803 the British declared war.

Cadoudal, Pichegru and the Duc d'Enghien.—The peace settlement had brought about the life consulate; the return of war was to stimulate the formation of the empire. The British government, which would have been glad to see Bonaparte deposed or removed by assassination, renewed its subsidies to the French royalists, who resumed their agitation and plotting. The most notable conspiracy was hatched by a young Chouan, Georges Cadoudal, and by a former republican general, Charles Pichegru, who had been deported from France after the *coup d'état* of 18 Fructidor but had escaped from Guiana and taken refuge in England. The police soon got wind of the conspiracy and arrested Pichegru on Feb. 29, 1804, and Cadoudal on March 9. Bonaparte decided to react vigorously enough to deter his opponents from any more such attempts. The police believed that the real head of the conspiracy was the young duc d'Enghien who was residing in the duchy of Baden, a few miles across the frontier. Accordingly, with the agreement of Talleyrand and the police chief Joseph Fouché, Bonaparte had the duc kidnaped on neutral soil and brought to Vincennes, where he was tried and shot (March 21). This action provoked a resurgence of opposition in the old aristocracy but enhanced the influence of Fouché.

THE EMPIRE, 1804–14

In the hope of consolidating his own position, Fouché now suggested to Bonaparte that the best way to discourage conspiracy would be to transform the life consulate into a hereditary empire, as the existence of an heir would remove all hope of changing the regime by assassination. Bonaparte readily accepted the suggestion. The senate, prompted by Fouché, then proposed a hereditary succession, and the tribunate expressed the wish that Bonaparte should be proclaimed hereditary emperor of the French. The empire was proclaimed on May 18, 1804, and a plebiscite approved the change.

The Institutions of the Empire.—Though there was little change in the organization of the government of France, Napoleon as emperor set himself to bring back a number of institutions similar to those of the *ancien régime*. In the first place he wanted to be consecrated—but by the pope himself, so that his coronation should be even more impressive than that of the kings. Pius VII agreed to come to Paris, and the ceremony, which seemed equally outrageous to royalists and to the old soldiers of the Revolution, took place in Notre Dame on Dec. 2, 1804. At the last moment, the emperor took the crown from the pope and set it on his own head himself. The imperial regime moreover had its symbols and titles. The Roman eagle was placed above the tricolor flag and was shown, together with the golden bees, in the coat of arms of the new dynasty. Princely titles were brought back for the members of Napoleon's family in 1804, and an imperial nobility was created in 1808. As opposition was still lively, Napoleon intensified his propaganda and imposed an increasingly strict censorship on the press. A dictatorial regime allowed him to carry on his wars for years without worrying about French public opinion.

Having been president of the Italian republic (as the Cisalpine was renamed) since Jan. 1802, Napoleon in March 1805 was proclaimed king of Italy. He was crowned in Milan on May 26.

The Projected Invasion of England: Trafalgar.—From 1803 to 1805 Napoleon had only the British to fight (*see* NAPOLEONIC WARS); and again France could hope for victory only by landing an army in the British Isles, while the British could defeat Napoleon only by forming a continental coalition against him. Napoleon began to prepare an invasion again, but with greater conviction this time and on a larger scale: he gathered nearly 2,000 ships between Brest and Antwerp and concentrated his "Grande Armée" in the camp at Boulogne (1803). Even so, the problem was the same as in 1798: to cross the Channel, the French had to have control of the sea. Still far inferior to the British navy, the French fleet needed the help of the Spanish;

and even then the two fleets together could not hope to defeat more than one of the British squadrons. Spain was induced to declare war on Great Britain in Dec. 1804, and it was decided that French and Spanish squadrons, massed in the Antilles, should lure a British squadron into these waters and defeat it, thus making the balance roughly equal between the Franco-Spanish navy and the British: a battle in the entrance to the Channel could then be engaged with some chance of success. The plan failed: the French squadron from the Mediterranean, under Adm. Pierre de Villeneuve, found itself alone at the appointed meeting place in the Antilles. Pursued by Nelson and not daring to attack him, it turned back toward Europe and took refuge in Cadiz on July 18, 1805; there the British blockaded it. Accused of cowardice by the angry Napoleon, Villeneuve resolved to run the blockade, with the support of a Spanish squadron, in order to reach Toulon; but on Oct. 21, 1805, he was attacked by Nelson off Cape Trafalgar. Nelson was killed in the battle, but the Franco-Spanish fleet was totally destroyed. The British had won a decisive victory, which eliminated the danger of invasion and gave them complete freedom of movement at sea.

The Victories in Europe (1805–07).—By this time, after two years of effort, the British had managed to organize a new continental coalition, in which Austria, Russia, Sweden and Naples were grouped against France. On July 24, 1805, three months before Trafalgar, Napoleon had ordered the Grande Armée from Boulogne to the Danube (thus even if the French had won at Trafalgar, the battle would not have been followed by the invasion of England). In the week preceding Trafalgar, the Grande Armée won an outstanding victory over the Austrian general Karl Mack, whose army surrendered at Ulm on Oct. 20; and on Nov. 13 Napoleon entered Vienna. On Dec. 2, 1805, he defeated the combined Austrian and Russian armies in the battle of Austerlitz, the greatest victory of his career. By the peace of Pressburg (Bratislava; Dec. 26, 1805) Austria renounced all influence in Italy and ceded Venetia and Dalmatia to Napoleon, as well as extensive territory in Germany to his protégés Bavaria, Württemberg and Baden. The French then proceeded to dethrone the Bourbons in the kingdom of Naples, which was bestowed on Napoleon's brother Joseph. In July 1806 the Confederation of the Rhine was founded—soon to embrace all western Germany in a union under French protection.

In Sept. 1806 Prussia entered the war against France; but on Oct. 14 the Prussian armies were defeated at Jena and at Auerstädt. The Russians put up a better resistance at Eylau (Feb. 8, 1807), but were routed at Friedland (June 14). In Warsaw, Napoleon fell in love with a Polish lady, Countess Marie Walewska (née Laczynska; 1786–1817), by whom he had a son, Alexandre Walewski.

Tilsit.—The Russian emperor Alexander I could still have gone on with the struggle, but was tired of the alliance with the British. He met Napoleon at Tilsit, in northern Prussia near the Russian frontier, on a raft anchored in the middle of the Niemen river. Three treaties were signed there: a Franco-Russian peace treaty (July 7, 1807), whereby Alexander consented to Napoleon's plans for Germany and Italy and ceded the Ionian Islands to France; a secret treaty of alliance between France and Russia (also July 7); and a Franco-Prussian peace treaty (July 9), whereby the Polish provinces were detached from the kingdom of Prussia to form the duchy of Warsaw. The two emperors thus shared the domination of Europe, Napoleon taking the west and Alexander the east; and Alexander even made a vague promise to attack, by land, the British possessions in India.

The Continental System.—As Napoleon could no longer think of invading England, he tried to induce capitulation by stifling the British economy. His idea was to produce artificially a state of overproduction in Great Britain by means of a continental blockade which would close the whole of Europe to British products: merchandise from the factories would accumulate in the English docks, the factories would soon have to be shut down, and then the unemployed workmen would rise against the government and force it to sue for peace. The decrees of Berlin (Nov. 21, 1806) and of Milan (Dec. 17, 1807) organized the continental system (*q.v.*): they forbade all trade with the British Isles, ordered the confiscation of all goods coming from English factories or from the British colonies and condemned as fair prize not only every British ship, but also every ship which had touched the coasts of England or its colonies or had merely allowed a British vessel to visit it.

Portuguese and Spanish Resistance (1808).—For the blockade to succeed, it had to be enforced rigorously throughout Europe; but from the beginning one country showed itself reluctant to comply. This was England's old ally Portugal, for whom the blockade meant commercial ruin. Napoleon decided to break down Portuguese opposition by force. Charles IV of Spain willingly let the French troops cross his kingdom and they occupied Lisbon; but the prolonged presence of Napoleon's soldiers in the north of Spain exasperated the inhabitants, who accused the king and his minister Godoy of treason. When insurrection broke out, Charles IV abdicated in favour of his son Ferdinand but then appealed to Napoleon for reinstatement. Seeing the opportunity to rid Europe of its last Bourbon rulers, Napoleon summoned the Spanish royal family to Bayonne in April 1808 and obtained the abdication of both Charles and Ferdinand (May 5 and 6); they were interned in Talleyrand's château of Valençay. The people of Madrid, however, had already risen against the French occupying troops on May 2; the rising was bloodily suppressed, but insurrection soon spread across the whole country, as the Spaniards would not accept Joseph Bonaparte as king. Gen. Pierre Dupont's army corps, sent to suppress the revolt in Andalusia, was forced to capitulate at Bailen in July; and this sensational blow to Napoleon's prestige was followed by another in August, when Andoche Junot's corps in Portugal capitulated to the British under the convention of Cintra. The Iberian peninsula, now up in arms, was henceforth to be a bridgehead on the continent for the British, and under the energetic Arthur Wellesley (later duke of Wellington), in command from 1809, the Anglo-Spanish-Portuguese forces were to achieve decisive successes (*see* PENINSULAR WAR).

Erfurt (1808) and Austria's War of 1809.—At the congress of Erfurt (Sept.–Oct. 1808), where Napoleon assembled a great concourse of princes to impress the Russian emperor, he could not extract from Alexander the definite promises to help that he required. Alexander's refusal, furthermore, was partly prompted by Talleyrand, who was already beginning to betray his master.

In 1809, however, with most of the Grande Armée thrown into Spain, Napoleon seemed on the point of overcoming the revolt. Then, in April 1809, Austria launched an attack in Bavaria in the hope of rousing all Germany against the French. Napoleon had to recall some of his forces from Spain, and Vienna fell again to the French on May 12. After their bloody defeat at Wagram (July 6), the Austrians obtained an armistice (July 12); and by the peace of Vienna in October, Napoleon took the Illyrian provinces from Austria, thus stopping a gap in the continental system.

Napoleon's Zenith.—The year 1810 was that of Napoleon's zenith, despite some failures in Spain and Portugal. He considered himself Charlemagne's heir. He repudiated Joséphine, who had not given him a child, so that he could marry the archduchess Marie Louise, daughter of the Austrian emperor Francis I; and the birth of a son, the king of Rome, in March 1811 seemed to assure the destiny of the empire. This empire, now at its greatest extent, included not only the Illyrian provinces but also Etruria, some of the papal states, Holland and the German states bordering the North sea. Around the empire proper there was a ring of vassal states ruled over by the emperor's relatives: the kingdom of Westphalia (Jérôme Bonaparte); the kingdom of Spain (Joseph Bonaparte); the kingdom of Italy (with Eugène de Beauharnais, Joséphine's son, as viceroy); the kingdom of Naples (Joachim Murat, Napoleon's brother-in-law); and the principality of Lucca and Piombino (Félix Baciocchi, another brother-in-law). Finally other territories were closely bound to the empire by treaties: the Swiss confederation, of which Napoleon was the mediator; the Confederation of the Rhine; and the duchy of Warsaw. Even Austria seemed bound to France by Napoleon's marriage to Marie Louise.

The political map of Europe, which had been so complicated

before 1796, was now greatly simplified. At the same time the frontiers did not coincide either with geographical features or with "nationalities." Whatever he may later have said, Napoleon while he was in power was not interested in realizing either German or Italian unity. Yet by reducing the number of states, by pushing the frontiers about, by amalgamating populations and by propagating institutions like those which the Revolution and nationalism had created in France, he prepared the ground for German and Italian unification. National feeling in Europe, stirred by French ideas and by contact with Frenchmen, gave rise in turn to the first resistance against French domination. From 1809 onward Spanish guerrillas, supported by British troops, were consistently successful in the peninsula, harassing the French and keeping them constantly on the move; and the national *Cortes*, convened at Cadiz by the insurrectionary element in Sept. 1810, promulgated in March 1812 a constitution inspired jointly by the ideas of the French Revolution of 1789 and by British institutions.

The Disaster in Russia (1812).—Since the congress of Erfurt the Russian emperor had shown himself less and less inclined to implement the treaty of Tilsit. In the spring of 1812, therefore, in order to intimidate him, Napoleon massed his forces in Poland; they amounted to about 453,000 men, drawn from every region of the empire and even including contingents extorted from Prussia and from Austria. After some last attempts at agreement, this Grande Armée began to cross the Niemen in the last week of June. The Russians retreated, scorching the earth behind them. Delayed in its advance by the difficulty of getting supplies, Napoleon's army did not reach the approaches to Moscow till the beginning of September. The Russian commander in chief, M. I. Kutuzov, engaged it at Borodino on Sept. 7: the fight was savage, bloody and indecisive, but on Sept. 14 Napoleon entered Moscow, which the Russians had abandoned. On that same day, a huge fire broke out, which destroyed the greater part of the town. Moreover, contrary to Napoleon's expectations, Alexander refused to treat with him. Withdrawal was necessary, and the premature onset of winter made it disastrous. After the difficult crossing of the Berezina in November, fewer than 10,000 men fit for combat remained with Napoleon's main force.

This catastrophe stirred all the peoples of Europe to withstand Napoleon's domination. In Germany the news let loose an outbreak of anti-French demonstrations which Prussia, having carefully prepared them, was ready to exploit. The Prussian troops, under Gen. Hans Yorck von Wartenburg, deserted the Grande Armée (Dec. 1812) and turned against the French. Following the Prussian example, the Austrians also withdrew their troops and adopted an increasingly hostile attitude. In Italy the people were moving away from Napoleon, and the "patriots" looked either to Eugène de Beauharnais or to Murat for the unification of the peninsula.

Even in France, signs of discontent with the regime were becoming more frequent. Talleyrand and Fouché were acting treacherously. In Paris a malcontent general, C. F. de Malet, nearly succeeded in carrying out a *coup d'état* when he announced, on Oct. 23, 1812, that Napoleon had died in Russia. This incident was a major factor in Napoleon's decision to hasten back to France ahead of the Grande Armée. Arriving in Paris on Dec. 18, he proceeded to stiffen the dictatorship, to raise money by various expedients and to levy new troops.

The Battle of Leipzig.—In 1813, therefore, the forces arrayed against France were no longer armies of mercenaries but nations fighting for their freedom as the French had fought for theirs in 1792 and 1793; and the French themselves, for all their courage, had lost their former enthusiasm. The emperor's ideal was no longer that of the nation.

In May 1813 Napoleon won some successes against the Russians and Prussians in Saxony and Lusatia (battles of Lützen and Bautzen) but his decimated army needed reinforcement and reorganization, and the armed mediation of Austria induced him to agree to an armistice, during which a congress was to meet at Prague under Metternich's presidency. Austria, the arbiter of the situation, proposed very honourable conditions: the French empire was to return to its natural limits; the duchy of Warsaw and the Confederation of the Rhine were to be dissolved; and Prussia was to return to its frontiers of 1805. Napoleon made the mistake of hesitating too long, and the congress had closed (Aug. 10) before his reply arrived. Austria declared war.

The French were now in a worse situation than in the spring. The numerical superiority of the allies was increasing every day, as one German contingent after another left Napoleon to go over to the other side. The greatest cataclysm of the Napoleonic era was the battle of Leipzig or "battle of the Nations" (Oct. 16–19, 1813), in which the Grande Armée was torn to shreds.

The reverse of the French degenerated fast into collapse. The French armies in Spain, forced to retreat, had been defeated at Vittoria (June 21, 1813); and by October the British were attacking their defenses north of the Pyrenees. In Italy the Austrians took the offensive, crossed the Adige and occupied Romagna. Murat, now openly a traitor to the emperor who had made him king of Naples, entered into negotiations with the Viennese court. The Dutch and the Belgians demonstrated against Napoleon.

Downfall and Abdication (1814).—In Jan. 1814 France was being attacked on all its frontiers. The allies cleverly announced that they were fighting not against the French people, but against Napoleon alone, since he had rejected the terms offered at Frankfurt (Nov. 1813), whereby the French would have preserved their "natural frontiers." The extraordinary feats of strategy which the emperor achieved during the first three months of 1814 with the army of young conscripts were not enough: he could neither defeat the allies, with their overwhelming numerical superiority, nor arouse the majority of French people from their resentful torpor. The *corps législatif* and the senate, formerly so docile, were now asking for peace and for civil and political liberties.

The treaty of Chaumont, signed on March 9, 1814, by Austria, Russia, Prussia and Great Britain, was a general pact such as France's enemies had failed to concert since 1793: the signatories bound themselves together for 20 years, undertook not to negotiate separately and promised to continue the struggle till Napoleon should have been overthrown. They then marshaled their forces and marched resolutely on Paris. They were at the gates of Paris on March 30, while Napoleon had moved east so that he could attack their rear guard. The Parisian authorities, no longer overawed by the emperor, lost no time in treating with the allies. The senate instituted a provisional government, with Talleyrand as president; he proclaimed the deposition of the emperor and, without consulting the French people, addressed himself to Louis XVIII, whose restoration the British alone were favouring.

Napoleon had been at Vitré when he learned of the advance on Paris. He had then ordered his army to turn westward again, but had only reached Fontainebleau when he heard that Paris had capitulated. He wanted to organize a new line of resistance south of the capital, but on April 4, 1814, a majority of his marshals explained to him that his troops, worn out and demoralized, could hold out no longer. Marshal Ney ended the discussion by advising the emperor to abdicate. Napoleon at first refused to follow this suggestion, but in the night of April 4–5 he learned that Marmont, in command of his vanguard, had just gone over to the enemy with a whole army corps. Fontainebleau was no longer protected, and on April 6 Napoleon abdicated.

By the treaty of Fontainebleau (April 11) the allies assigned the Mediterranean island of Elba to Napoleon as his place of residence, with full sovereignty over it; he was allowed to take there a corps of 400 volunteers and was granted a personal income of 2,000,000 francs, to be provided by Louis XVIII, as well as other financial provisions; also, he retained the title of emperor. The empress Marie Louise was to have the Italian duchies of Parma, Piacenza and Guastalla. After unsuccessfully trying to poison himself, Napoleon spoke his farewell to his "Old Guard," gathered in the courtyard of the "Cheval Blanc" on April 20. After a hazardous journey, during which he narrowly escaped assassination, he arrived at Elba on May 4.

ELBA AND THE HUNDRED DAYS, 1814–15

The island of Elba, on which Napoleon was to live and reign, was only a few square miles in size. "I want from now on to live

like a justice of the peace," he declared. But he was only 45 and in the full possession of his faculties. Could a man of such energy and imagination resign himself so easily to defeat?

In France, moreover, the Bourbon Restoration was soon exposed to criticism. Though in 1814 the majority of the French people were tired of the emperor, they had expressed no wish for the return of the Bourbons and were in any case strongly attached to the essential achievements of the Revolution; and Louis XVIII had come back "in the baggage train of the foreigners" with the last surviving *émigrés* who had "learnt nothing and forgotten nothing" and whose influence seemed to threaten most of the Revolution's achievements. The apathy of April 1814 quickly gave way to mistrust. Old hatreds were revived, resistance organized and conspiracies formed.

From Elba, Napoleon kept a close watch on the continent. He knew that some of the diplomats at Vienna, where a congress was deciding the fate of Europe, considered Elba too close to France and to Italy and wanted to banish him to a distant island in the Atlantic. Also he accused Austria of preventing Marie Louise and his son from coming to join him (in fact she had taken a lover and had no intention of going to live with her husband). Finally the French government refused to carry out the financial clauses of the treaty of Fontainebleau, so that Napoleon was in danger of being reduced to penury.

The Hundred Days.—All these considerations drove Napoleon to action. Decisive as ever, he returned to France like a thunderbolt: on March 1, 1815, he landed in the Gulf of Juan with a detachment of his guard. As he crossed the Alps, the republican peasants rallied round him, and at Laffrey, near Grenoble, he captivated the soldiers dispatched to arrest him. Thenceforward "the eagle flew from steeple to steeple until it reached the towers of Notre Dame." On March 20 he was in Paris.

Napoleon was brought back to power rather as one who embodied the spirit of the Revolution than as the emperor who had fallen a year before. To maintain himself and to rally the mass of Frenchmen to his cause he should have allied himself steadfastly with the Jacobins; but this he did not dare. Unable to escape from the *bourgeoisie* whose preponderance he himself had assured and who feared above all else a revival of the socialist experiments of 1793 and 1794, he could only set up a political regime scarcely distinguishable from that of Louis XVIII. Enthusiasm ebbed fast, and the Napoleonic adventure seemed a dead end. When the *Acte additionnel* which modified the imperial constitution was submitted to a plebiscite, only about 1,500,000 citizens voted—a small majority.

Napoleon mustered an army to oppose the allied troops massing on the frontiers. With it he marched into Belgium and defeated the Prussians at Ligny on June 16, 1815. Two days later, at Waterloo, he met the British under Wellington, the victor of the Peninsular War. A savage battle followed. Napoleon was in sight of victory when the Prussians under Blücher arrived to reinforce the British. "Victory changed sides" and soon, despite the heroism of the Old Guard, Napoleon was overthrown. (*See* WATERLOO CAMPAIGN.)

The Second Abdication.—Back in Paris, Napoleon was forced to abdicate by the legislative chambers: he did so, in favour of his son, Napoleon II, on June 22, 1815. On July 3 he was at Rochefort, intending to take ship for the United States, but a British squadron prevented any French vessel from leaving the port. Napoleon then decided to appeal to the British government for protection. Capt. F. L. Maitland, in command of the "Bellerophon," one of the blockading ships, told him that his request might be granted; and on July 13, Napoleon wrote his famous letter to the British prince regent (later George IV):

> Royal Highness,
> A prey to the factions which divide my country and to the hostility of the greatest powers of Europe, I have ended my political career, and I am going, like Themistocles, to seat myself at the hearth of the British people. I put myself under the protection of its laws, which I ask from Your Royal Highness, as from the most powerful, the most constant, and the most generous of my enemies.

Having apprised Maitland of his decision on July 14, Napoleon boarded the "Bellerophon" in the morning of July 15, 1815. The allies were agreed on one point: Napoleon was not to go back to Elba. Nor did they like the idea of his going off to America. It would have suited them if he had fallen a victim to the "white terror" or if Louis XVIII had had him summarily tried and executed. Great Britain had no choice but to send him to detention in a far-off island. On July 30, 1815, the British government announced that General Bonaparte could not be allowed to retain the means of disturbing the peace of the continent again; that the island of St. Helena had been chosen for his residence; and that its position would allow him to be treated with much greater indulgence than would be possible elsewhere, in view of the precautions that had to be taken to guard his person. Napoleon protested eloquently: "I appeal to history!"

ST. HELENA, 1815–21

When the "Bellerophon" reached Plymouth, Napoleon was transferred to the "Northumberland," which on Aug. 10, 1815, set sail for St. Helena. Meanwhile, France was paying heavily for the escapade of the Hundred Days. The second treaty of Paris (Nov. 1815) deprived the French of some frontier districts which had belonged to them even before the Revolutionary Wars, as well as of the part of Savoy which had been left to France in 1814. A "white terror" more violent than ever was let loose throughout the country, and the counterrevolutionaries came to power, where they were to remain for 15 years.

On Sunday, Oct. 15, 1815, the "Northumberland" dropped anchor off St. Helena. Napoleon disembarked with those followers who were voluntarily accompanying him into captivity: Gen. Bertrand, grand marshal of the palace, and his wife; the comte de Montholon, aide-de-camp, and his wife; Gen. Gourgaud; Las Cases, the former chamberlain; and several servants, including the valet Louis Marchand. They were all settled in The Briars, the property of an Englishman, William Balcombe, since the great house of Longwood was not yet ready for them. On Dec. 10, however, they moved to Longwood, though work on the house was still to go on throughout Napoleon's captivity.

Napoleon settled down to a life of routine. He got up late, breakfasting about 10 A.M., but seldom went out. He was free to go anywhere on the island so long as he was accompanied by an English officer, but he soon refused to comply with this condition and so shut himself up in the grounds of Longwood. He wrote and talked much. At first Las Cases acted as his secretary, compiling what was later to be the *Mémorial de Sainte-Hélène* (first published in 1823). From 7 to 8 P.M. Napoleon had dinner, after which a part of the evening was spent in reading aloud—Napoleon liked to hear the classics. Then they played cards, a favourite game being "reversis." About midnight Napoleon went to bed. Some of his time was devoted to learning English, and he eventually took to reading English newspapers; but he also had a large number of French books sent from Europe, which he read attentively and annotated.

St. Helena has a healthful climate, and Napoleon's food was good, carefully prepared and plentiful. The deterioration of his health in exile must have been due, in part at least, to inactivity. The man who for 20 years had played so great a role in the world and who had marched north, south, east and west across Europe could hardly be expected to endure the monotony of existence on a little island, aggravated by the reclusion that he had voluntarily imposed on himself. He had also more intimate reasons for unhappiness: Marie Louise sent no word to him, and he may have learned of her liaison with the Austrian officer appointed to watch over her, Graf A. A. von Neipperg (whom she eventually married in secret without waiting for Napoleon's death); nor did he have any news of his son, the former king of Rome, who was now living in Vienna with the title of duke of Reichstadt. Finally, though the severity of Sir Hudson Lowe has been much exaggerated, it is certain that this "jailer," who arrived as governor of St. Helena in April 1816, did nothing to make Napoleon's life easier. Napoleon from the start disliked him as the former commander of the Corsican rangers, a band of volunteers recruited by the British in the recent wars and largely composed of enemies of the Bonaparte

family. Obsessed by his responsibilities and always anxious to carry out his instructions exactly, Lowe came into conflict with Las Cases, whom he saw as Napoleon's confidant, as early as Nov. 1816: he had him arrested and expelled. Thenceforward relations between the governor and Napoleon were limited strictly to those stipulated by the regulations.

Napoleon showed the first signs of illness at the end of 1817; he seems to have had an ulcer or a cancer of the stomach. The Irish doctor Barry O'Meara, having asked in vain for a change in the conditions under which Napoleon lived, was dismissed; so also was his successor John Stokoe, who was likewise thought to be well-disposed toward Napoleon. The undistinguished Corsican doctor who took their place, C. F. Antommarchi, prescribed a treatment that could do nothing to cure his patient. It is uncertain, however, whether Napoleon's disease was curable at all, even by 20th-century methods.

From the beginning of 1821 the illness became rapidly worse. From March, Napoleon was confined to bed. In April he dictated his last will: "I wish my ashes to rest on the banks of the Seine, in the midst of that French people which I have loved so much. . . . I die before my time, killed by the English oligarchy and its hired assassins." On May 5 he spoke a few coherent phrases: "My God . . . The French nation . . . my son . . . head of the army. . . ." He died at 5:49 P.M. on that day, not yet 52 years old. His body was dressed in his favourite uniform, that of the Chasseurs de la Garde, covered by the gray overcoat that he had worn at Marengo. The funeral was conducted simply, but with due propriety, in the Rupert valley where Napoleon had sometimes walked, beside a stream in which two willows were reflected. The stone covering his tomb bore no name, only the words *"Ci-gît"* ("Here lies").

THE NAPOLEONIC LEGEND

Napoleon's fall had set loose a torrent of hostile books designed to sully the great man's reputation. One of the least violent of these was Chateaubriand's pamphlet *De Buonaparte, des Bourbons, et de la nécessité de se rallier à nos princes légitimes* (1814). But this literature soon died down, while the task of defending

GIRAUDON, PARIS

TOMB OF NAPOLEON, HOTEL DES INVALIDES, PARIS

Napoleon was taken up. Byron had published his "Ode to Napoleon Buonaparte" as early as 1814; Heine wrote his ballad "Die Grenadiere"; and in 1817 Stendhal began his *Vie de Napoléon.* At the same time the emperor's most faithful supporters were working together, talking about him and distributing reminders of him, engravings, etc. They idealized his life ("What a novel my life is!" he himself had said) and began to create the Napoleonic legend.

As soon as the emperor was dead, the legend grew rapidly. Memoirs, notes and narratives by those who had followed him into exile contributed substantially to it. In 1822 Dr. O'Meara, in London, published *Napoleon in Exile, or A Voice from Saint Helena;* in 1823 Montholon and Gourgaud began to publish the *Mémoires pour servir à l'histoire de France sous Napoléon, écrits à Sainte-Hélène,* while Las Cases, in his famous *Mémorial,* presented the emperor as a republican opposed to war who had fought only when Europe forced him to fight in defense of freedom; and in 1825 Antommarchi published his *Derniers momens de Napoléon.* Thereafter the number of books in Napoleon's honour increased continually; the year 1827 saw Victor Hugo's "Ode à la Colonne," the completion of A. J. F. Fain's series of recollections of the years 1812–14, the 28 volumes of the *Victoires et conquêtes des Français,* Walter Scott's *Life of Napoleon Buonaparte* and the first volume of J. Marquet de Montbreton de Norvins' *Histoire de Napoléon.* Neither police action nor prosecutions could prevent books, pictures and objects reminiscent of the imperial saga from multiplying in France.

After the July revolution (1830), when thousands of tricolor flags had appeared in windows, Louis Philippe's government had not only to tolerate the growth of the legend but even to promote it: in 1833 the statue of Napoleon was put back on the top of the column in the Place Vendôme in Paris; and in 1840 the king's son François, prince de Joinville, was sent in a warship to fetch the emperor's remains from St. Helena to the banks of the Seine in accordance with his last wishes. A magnificent funeral was held in Paris on Dec. 14, 1840, and Napoleon's body was conveyed, through the Arc de Triomphe in the Place de l'Étoile, to entombment under the dome of the Invalides.

Napoleon's nephew Louis Napoléon (*see* NAPOLEON III) exploited the legend in order to seize power in France. Though his attempts at Strasbourg in 1836 and at Boulogne in 1840 were failures, it was chiefly thanks to the growth of the legend that he won election to the presidency of the second republic, with an overwhelming majority, in 1848 and was able to carry out the *coup d'état* of Dec. 2, 1851, and to make himself emperor in 1852.

The disastrous end of the second empire in 1870 damaged the Napoleonic legend and gave rise to a new anti-Napoleonic literature, best represented by Hippolyte Taine's *Origines de la France contemporaine* (1876–94). World Wars I and II, however, together with the experience of the 20th-century dictatorships, made it possible to judge Napoleon more fairly. Any comparison with Stalin or Hitler, for instance, can only be to Napoleon's advantage. He was tolerant; he released the Jews from the ghettoes; and he showed respect for human life. Brought up on the *Encyclopédie* and on the writings of the *philosophes* of the Enlightenment, he was always above all, as has already been said, a man of the 18th century, the last of the "enlightened despots."

Conclusions.—One of the gravest accusations made against Napoleon is that he was the "Corsican ogre" who sacrificed millions of men to his ambition. Precise calculations show that the Napoleonic Wars of 1804–15 cost France itself about 500,000 men; *i.e.,* about one-sixtieth of the population. The loss of these young men, furthermore, seems to have had a notably adverse effect on the birth rate.

The social structure of France changed little under the empire. It remained roughly what the Revolution had made it: a great mass of peasants (75%), half of them being the working owners of their farms or sharecroppers, the other half having too little land for their own subsistence and hiring themselves out as labourers. Industry, stimulated by the war and the continental system, made remarkable progress in northern and eastern France, whence exports could be sent to central Europe; but it declined in

the south and west because of the closing of the Mediterranean and the Atlantic. The great migrations from rural areas toward industry in the towns began only after 1815. The nobility, hard hit by the Revolution, would probably have declined more swiftly if Napoleon had not restored it; but it could never recover its former privileges, and its attempt to reassert itself politically after 1815 came to nothing.

Above all, Napoleon left durable institutions, the "granite masses" on which modern France has been built up: the administrative system of the prefects, the Code Napoléon, the judicial system, the Banque de France and the financial organization, the university and the military academies. He made a lasting mark on the history of France—and of the world.

BIBLIOGRAPHY.—By the middle of the 20th century the literature on Napoleon already numbered more than 100,000 volumes, and new books were still appearing every month. Only the most important works can be listed here. For fuller bibliography *see* F. M. Kircheisen, *Bibliographie napoléonienne* (1902) and *Bibliographie du temps de Napoléon*, 2 vol. only published (1908–12); G. Davois, *Bibliographie napoléonienne française jusqu'en 1908*, 3 vol. (1909–11); L. Villat, *La Révolution et l'Empire*, vol. ii (1942).

Sources: Apart from the mass of original documents in archives throughout Europe, the essential source is the *Correspondance de Napoléon*, 28 vol. (1858–69), published by order of Napoleon III, together with the *Oeuvres de Napoléon à Sainte-Hélène*, 4 vol. (1870); but this collection is incomplete, containing only 22,000 out of 30,000 documents, and occasionally some tampering with the texts has taken place. It should thus be supplemented with the following collections: L. Lecestre (ed.), *Lettres inédites de Napoléon Ier*, 2 vol. (1897); L. de Brotonne (ed.), *Lettres inédites de Napoléon Ier* (1898) and *Dernières lettres inédites* (1903); A. Chuquet (ed.), *Ordres et apostilles de Napoléon*, 4 vol. (1911–12); E. Picard and L. Tuetey, *Correspondance inédite de Napoléon*, 4 vol. (1912–13); C. F. Palmstierna (ed.), *Marie-Louise et Napoléon; lettres inédites, 1813–1814* (1955); L. Madelin (ed.), *Lettres de Napoléon Ier à Marie-Louise, écrites de 1810 à 1814*, 2nd ed. (1960). For Napoleon's itinerary *see* A. Schuermans, *Itinéraire général de Napoléon Ier* (1908); L. Garros, *Itinéraire de Napoléon* (1950). Further firsthand information is also to be found in the letters and memoirs of members of Napoleon's entourage, military and civil, but these again are too numerous to be cited individually here.

General Biographies: P. Lanfrey, *Histoire de Napoléon Ier*, 5 vol. (1867–75); A. Fournier, *Napoleon I.: eine Biographie*, 3 vol (1886–93); F. Masson, *Napoléon et sa famille*, 13 vol. (1897–1919); J. Holland Rose, *The Life of Napoleon I*, 2 vol. (1902); E. Ludwig, *Napoleon* (1925); E. Driault, *La Vraie Figure de Napoléon* (1928); J. M. NAPOLEON II: *see* REICHSTADT, NAPOLÉON FRANÇOIS JOSEPH CHARLES, DUKE OF.

NAPOLEON III (1808–1873), emperor of the French from 1852 to 1870, was born in Paris on April 20, 1808, the third son of the emperor Napoleon I's brother Louis Bonaparte, king of Holland from 1806 to 1810, and his wife Hortense de Beauharnais (*see* BONAPARTE; HORTENSE; the doubts cast on his paternity have never been substantiated). He was originally named Charles Louis Napoléon, the form LOUIS NAPOLEON coming into use after the death in 1831 of his brother Napoléon Louis (his parents' eldest son, Napoléon Charles, had died in 1807). His youth was largely spent in exile, since on the downfall of Napoleon I in 1815 all the Bonapartes had to flee from France; and he was brought up by his mother in Germany, Switzerland and Italy. His education was rather unsystematic and fragmentary: he attended the *Gymnasium* at Augsburg for a time (where he is said to have ranked fourth in a class of 94); he received private tutoring first from the abbé Bertrand and then from Philippe Le Bas, the son of a Jacobin regicide; and finally he was given military training in the Swiss army. His earliest ambition was to be a soldier like his uncle, but later he turned increasingly to politics, for which he had real gifts. As early as Dec. 1830 he was plotting a revolution in Rome that was to have proclaimed the duke of Reichstadt, Napoleon I's only son, as king of Rome and himself as regent. In 1831 he took part in the rising in Umbria directed against the tyranny and obscurantism of the papal government; his hope of "liberating Italy" dates from his earliest years.

The Napoleonic Propaganda, Strasbourg and Boulogne.—The death of his brother in 1831 and that of the duke of Reichstadt in 1832 made Louis Napoleon heir to his uncle's claims, since neither his father nor his uncles Joseph and Lucien wished to pursue them. Henceforth he gave all his energies to winning the throne of France, with a solid persistence and a faith in his destiny that defied all adversity, including mockery by his family for his vain ambitions. His prospects were actually not at all hopeless. He had first of all the advantage of the growing "Napoleonic legend," which was obtaining an increasing hold on French minds. Napoleon I's tyranny was being forgotten or glossed over as the memory of it grew dimmer, and instead his "glory," which contrasted so strikingly with the timidity and dullness of the *bourgeois* monarchy of Louis Philippe, was lauded nostalgically. Louis Napoleon moreover was an able propagandist, who saw clearly where his strength lay. In his pamphlet *Rêveries politiques* (1832) he declared that only an emperor could give France the desired glory, though he took care to point out, in the constitution which he outlined, that his aim would be to combine this glory with liberty. In 1836 he published a *Manuel d'artillerie*, which he distributed widely in the hope of drawing attention to himself and of proving that his military knowledge fitted him for the role of restorer of the empire. His multivolume work on the history of artillery (written with Col. Ildefonse Favé) was published during the years 1846–71.

The characteristic that distinguishes Louis Napoleon's early propaganda from his later work is his interest in and concentration on the army. He hoped at first to achieve his aims by a military *coup d'état*. On Oct. 30, 1836, accordingly, at 6 A.M., he presented himself before the garrison of Strasbourg in Napoleonic uniform

and invited the 4th artillery regiment, whose colonel (Claude Nicolas Vaudrey) he had previously won over, to follow him and revive the empire. He was acclaimed with shouts of *Vive l'Empereur*, but other portions of the garrison hesitated, some troops suspected that the revolt was a hoax, and within two hours Louis Napoleon was arrested. The king, Louis Philippe, anxious to conceal the fact that he had a rival, silently deported him to the United States without trial or fuss.

Louis Napoleon returned to Europe almost at once, in the spring of 1837, and resumed his plotting in Switzerland. Expelled from there as a result of pressure by the French government, he went to England. In London he became well-known as a man of fashion and formed a wide acquaintance in social and political circles: everywhere he struck people by the confidence with which he asserted that he would one day be emperor of France. In 1839 he brought out a booklet, *Des idées napoléoniennes* or *The Napoleonic Idea*, published in both French and English, in which he described his aims and political ambitions once more, though now in fuller detail. The Napoleonic idea was, he declared, the system which reconciled liberty and order, the conquests of the Revolution with the requirements of order, the principle of equality with that of a hierarchy based upon merit. Only a Napoleonic emperor, he declared, could provide a government strong enough for military achievement, for drastic social reforms and for economic improvements and yet rule according to the wishes of the people. He laid particular stress on his determination to be not a tyrant but the founder of liberty in France.

The broadening appeal of Louis Napoleon's propaganda can be seen in his looking beyond the army; but he still seemed to place his hopes on a military *coup d'état;* and in 1840, the year of the return of Napoleon I's "ashes" to France, he made one last attempt. On Aug. 6 he landed near Boulogne with about 50 followers and appealed to the garrison to rise in rebellion behind him. He was rebuffed and, together with all his party, arrested. This time he was brought to trial; and, as might be expected, he used the opportunity to advertise his claims: "I stand before you," he declared, "as the representative of a principle, a cause, a defeat. The principle is the sovereignty of the people; the cause is that of the empire; the defeat is Waterloo." Few could equal his gift for inventing striking formulas and he made some stir; but he was all the same sentenced to life imprisonment. He was incarcerated in the 13th-century fortress of Ham, but was nevertheless leniently treated; he was allowed servants and visitors and an uncensored correspondence and so could maintain his morale. He undertook studies designed to fit him for his throne; and he continued his propaganda. The most notable piece that he published in this period was an essay on *L'Extinction du paupérisme* (1844) which gave him some reputation in left-wing and working-class circles. He refused an offer of release conditional on his renouncing his political ambitions; but instead, on May 26, 1846, escaped dramatically from his prison disguised as a labourer.

The Presidency of the Second Republic.—Back in London, Louis Napoleon appears to have realized the importance of winning popular support; and so when the revolution of 1848 offered him new opportunities in France, he waited patiently for that support to mount. His friends (without his consent) put him up as a candidate for the national assembly, and in June he was triumphantly elected in four *départements;* but with masterly restraint he resigned his seat and waited till the tide should mount still higher in his favour. In the election of Sept. 1848 he was victorious in five *départements:* this time he took his seat, but was careful to refrain from revealing his grandiose ambitions and stressed his loyalty to the republic.

It was only at the end of the year 1848, when the parties in power had lost much of their credit and had shown aptitude only for squabbling among themselves and none for effecting improvements in the lot of the ordinary man, that Louis Napoleon stood for the presidency. The magic of his name gave him an overwhelming victory in the elections of Dec. 1848: he won 5,434,226 votes against Louis Eugène Cavaignac's 1,448,107, and A. A. Ledru-Rollin's 370,119. It will be noticed that his opponents were republicans; the royalists had decided to back him. It is usually stated that they did so because they thought him an easy tool, who would prepare the way for a royalist restoration when they were ready for it: but this is only partly true. Most of them backed him because they saw that he was bound to win, being the only candidate who was known to the peasants. Nevertheless, Louis Napoleon did come into office as an ally of the conservatives; he still had no political party of his own; and ministries and parliament continued therefore to be monopolized by men hostile to his ambitions.

The republican constitution made Louis Napoleon president for four years and did not allow him to be re-elected. He tried to arrange a revision of the constitution to enable him to remain for ten years; but though the royalists, split between Legitimists and Orleanists, could not agree among themselves on a king to replace him, they grew increasingly frightened by his rising prestige and power and refused to extend his term of office. Had they been willing to compromise, he might have been content with the presidency and perhaps never have become emperor. As it was, the hostility between him and the royalists mounted. Foreseeing a trial of strength, president and parliament each worked to win control of the army, and in the political sphere the president sought to gain a march over parliament by posing as the champion of the underdog. He demanded that parliament restore the vote to the 3,000,000 electors of the poorer classes whom it had disfranchised and thus increased his popularity. Finally, when it was clear that there was deadlock between them, Louis Napoleon on Dec. 2, 1851, declared parliament dissolved, arrested its principal leaders and about 20,000 of his enemies in a most efficiently executed *coup d'état* and appealed to the nation. In the plebiscite of Dec. 20 he was voted dictatorial powers for ten years by nearly 7,500,000 votes, with fewer than 650,000 votes cast against him.

The Second Empire Inaugurated.—In Nov. 1852 the president held another plebiscite and was elected emperor of the French; and on Dec. 2, 1852, he assumed the title of Napoleon III (Napoleon II was Napoleon I's son, technically assumed to have reigned in 1815). In Jan. 1853 he married the beautiful Spanish countess Eugénie (*q.v.*) de Montijo. Thus was inaugurated the brilliant and tragic period known as the second empire.

Foreign Policy.—When Napoleon III was preparing the ground for his assumption of the imperial dignity he declared that "the empire meant peace"; and to a certain extent this was not simply designed to lull the fears of Europe but expressed a genuine hope. His ambition in foreign affairs was to make his country a great power once more, on the same level as 50 years earlier, when France had been the champion of oppressed peoples and the redresser of European wrongs. It was one of his fundamental beliefs that the principle of nationalities was the most powerful driving force in 19th-century Europe, inexorable as well as just, and he wished to lead the powers in redrawing the map of the continent in accordance with it. In this way he would at the same time wipe out the memory of Waterloo and the humiliations imposed by the Congress of Vienna and peacefully extend the influence of France, for he was confident that the new states which he hoped to call into being (Poland, Italy, Germany, Rumania, Mexico) would be, as it were, satellites of their benefactor. In his long period of exile he had studied Napoleon I's career with the purpose of discovering what it was that ruined that great man; and one of his explanations was that Napoleon I had fought Great Britain. Napoleon III determined to avoid repeating this mistake; and his personal inclinations in any case urged him to ally himself with Great Britain, the leading liberal power, against the tyrannies of Austria and Russia. It is certain that he had no wish to renew his uncle's long and ruinous wars: he would try to achieve what Napoleon I had failed to do but he would seek to do it peacefully by political cunning, persuasion and alliances. He was not simply a French nationalist, but a genuinely altruistic idealist: there is no question of his projecting territorial conquests for France by aggressive war, but he did hope that his good services to the world would not go unrewarded and that the new map of Europe would be made to "balance" by an extension of French territory on the eastern borders as "compensation." The view (which some German historians have argued) that Napoleon III pursued France's traditional

policy of seeking conquests on the Rhine is unsubstantiated. On the contrary, he pursued a policy that was in many ways a departure from French traditions, and this undoubted fact played its part in bringing about his downfall.

It was probably his hesitation between idealism and self-interest that made Napoleon III's foreign policy almost uniformly unsuccessful. None of his projects ever worked out quite as he planned it and nearly all left him entangled in knots for which he had only himself to blame. The Crimean War (*q.v.*) of 1854–56 was his first and only entirely successful adventure. In conjunction with Great Britain, his favourite ally, he halted Russian expansion toward the Mediterranean (which some say he wished to make his special sphere of influence), paved the way for Rumanian independence and in one stroke appeared to win both clerical and liberal applause, for he both defended the Holy Places and destroyed the might of tsarist Russia. The Congress of Paris (1856), at which the peace terms were agreed, seemed to restore France to the leading position in Europe.

The emperor's success was short-lived. When he turned to the task of liberating Italy he met the first really serious difficulties of his reign, difficulties that were soon to multiply. He hoped that he could find a solution to the Italian problem which would be universally acceptable but he failed to please anyone entirely. On April 24, 1859, he declared war on Austria (after a carefully hatched secret intrigue with Cavour, prime minister of Sardinia-Piedmont, designed to make Austria technically the aggressor). His aim was to expel Austria from Italy and to establish an Italian confederation of four states under the presidency of Pope Pius IX. However, no sooner had he won a few victories than, horrified by the bloodshed (which he now saw for the first time) and frightened by Prussian military preparations on the Rhine, he suddenly signed preliminaries of peace with Austria at Villafranca in July. The Italian national movement slipped entirely out of his control and he eventually found himself confronted with a united Italian monarchy very different from the weak federation that he had planned. This new Italy was dissatisfied because neither Rome nor Venice was included; the pope and the French clericals were alienated because Napoleon had allowed the annexation of the papal states to the kingdom; and finally, when Napoleon received Nice and Savoy from Sardinia-Piedmont as a reward for his assistance, he lost the goodwill of Great Britain (*see* ITALIAN INDEPENDENCE, WARS OF; ITALY: *History*).

His grandiose plans for a new "Latin empire" in Mexico under the Austrian archduke Maximilian involved Napoleon in still further difficulties (1862–67): the invasion of the country proved much harder than he had foreseen; when it was at length accomplished the hostility of the United States compelled him to withdraw (1866–67); and finally Maximilian was executed by the Mexicans and his whole regime overthrown.

In Germany likewise Napoleon involved himself in humiliating contradictions. He personally favoured some unification of Germany, as he favoured unification of Italy, and he was consequently benevolently neutral when Prussia declared war on Austria in 1866 (*see* SEVEN WEEKS' WAR). He hoped that these two powers would exhaust themselves in a long struggle and that he would then be able to intervene as mediator and impose a settlement. Prussia's rapid victories found him so unprepared that (as had already happened in Italy) he found himself quite unable to keep up with events. He feebly asked Prussia for "compensations" on the Rhine, only to be rebuffed; and so began the hostility that was to culminate in the Franco-German War.

Napoleon's foreign policy is thus one of repeated disappointments, but also one which was primarily responsible for the reshaping of Europe on nationalistic lines. It should not be forgotten too that it was he who annexed Cochin China to France (1862) and so laid the basis of his country's subsequent expansion and empire in the far east; and that he so stimulated French naval development in the new fields of steam-propelled and ironclad ships that Great Britain's traditional supremacy on the seas seemed for a time to be seriously challenged. He was lucky here in having able advisers—the marquis Justin de Chasseloup-Laubat, minister of the navy and colonies, and Stanislas Dupuy de Lôme, the naval architect—who played really decisive and useful roles. He failed to use his foreign ministers so successfully: he repeatedly changed them, acted behind their backs and thus increased the confusion of his policy.

Domestic Policy.—"The Napoleonic Idea," wrote the future emperor in his youth, "is not an idea of war, but a social, industrial, commercial, humanitarian idea." The second empire coincided with the beginnings of the industrial revolution in France, and Napoleon, inspired by Saint-Simonian doctrines, distinguished himself both from the preceding and from the succeeding regimes in working actively to assist and accelerate this change. He gave great impetus to the foundation of institutions of credit, the construction of railways, the holding of industrial exhibitions, the draining and reclamation of waste land and the extension of public works, of which the rebuilding of Paris remains a surviving monument. Inspired by the example of Great Britain, he introduced a considerable amount of free trade with the Anglo-French commercial agreement of 1860 (the "Cobden treaty") despite much opposition, in the hope that it would encourage the modernization of industry. It was under his reign and with his encouragement that the effective organization of the working class began; and in 1864 combination for strikes was made legal. Though economic circumstances were to a considerable extent independent of him, there is no doubt that he contributed to making his reign one of remarkable and almost unprecedented prosperity. It was long remembered as such; and this gave considerable strength to the Bonapartist cause after 1870. Still, Napoleon had his disappointments in this sphere too. He said "I alone have busied myself with the workers"; but the workers turned socialist all the same. The industrialists whom he sought to stimulate gave him no thanks for increasing the competition that they had to meet because of his policy of free trade. Here again his dreams of progress involved difficulties he had not foreseen.

It was in his constitutional policy that Napoleon came nearest to success. The regime that he established in 1852 was highly authoritarian: it concentrated all important powers in the emperor and gave him a free hand in appointing the ministers and officials who ran the country. The legislature, though still elected by universal suffrage, had its rights drastically curtailed: it could not initiate bills, it could amend them only to a limited extent and its debates were published in censored form. Political activity in the country was virtually brought to an end, and opposition could be expressed only indirectly under heavy disguise in literary journals. However, in the first years of the empire this dictatorial regime was probably generally popular among a majority of the people, since the disorders of the republic and the fear of anarchy and socialism had produced a reaction in favour of strong government. It has often been stated that Napoleon maintained himself in office by force: Karl Marx, for example, declared that his principles were not liberty, equality and fraternity but "cavalry, infantry and artillery." Yet the peasants, who formed the bulk of the electorate, cared little for politics and were quite happy to vote as directed by Napoleon's agents, the prefects and the mayors; in return they obtained what they wanted most, namely material prosperity and improvements in the condition of their daily lives, subsidies for their village schools, roads and railways.

This system worked well enough in the 1850s, but began to collapse in the second decade of the reign. The "red menace" of 1852 was forgotten, the opposition parties revived and found ready weapons in the mistakes and hesitations of the government. The Italian war of 1859 ended Napoleon's alliance with the Catholics, who now took the lead in opposition, and they were joined by the manufacturers incensed by the free trade treaty. Napoleon met this challenge in an interesting and original way, which speaks well for his political acumen. He believed that it is "always public opinion which wins the last victory." "March at the head of the ideas of your century," he declared, "and these ideas follow you and support you. March behind them, and they drag you after them. March against them, and they overthrow you." He determined, therefore, that he would yield to the growing demand for liberty by granting it voluntarily while he still could, so as to capture the leadership of the new trend in public opinion. On

Nov. 24, 1860, he issued a decree increasing the powers of the legislature; and after further concessions from 1867 he invited the leader of the liberal opposition in parliament, Émile Ollivier, to form a responsible ministry at the end of 1869. Thus was his dictatorship transformed into a constitutional monarchy, and on May 8, 1870, the "Liberal empire" was approved in a plebiscite by an overwhelming vote of 7,359,000.

Napoleon seemed to have given his regime a new lease of life, for he had completely disarmed the majority of the opposition by granting most of their demands. The Liberal empire has been criticized for not being a real parliamentary democracy, and many historians have claimed that it was either consciously or unconsciously a sham, whose inherent contradictions inevitably caused its rapid collapse. There are grounds however for believing that Napoleon was trying to establish not parliamentary government but a form of "representative government" with a definite doctrine behind it; and that his Liberal empire was an original and worthwhile experiment which might have succeeded had the Franco-German War not destroyed it in its infancy.

Deposition and Exile.—The international situation appeared to be very calm when suddenly on July 2, 1870, it was revealed that the Spaniards had invited a German prince, Leopold of Hohenzollern-Sigmaringen, to be their king. This was taken to be a threat to the security of France, and the king of Prussia, William I, was asked to stop the prince's candidature and then—fatal mistake—to promise that he would never allow it to be revived. His refusal, turned into an insult by Bismarck, caused the French chamber on July 15 to vote for war against Prussia, which was declared on July 19 (*see* FRANCO-GERMAN WAR). Though ill with a disease of the bladder to the point of hardly being able to move, Napoleon took command of his troops and, largely through his prolonged hesitation, was quickly defeated and surrounded at Sedan. He surrendered on Sept. 2, and the third republic was proclaimed in Paris on Sept. 4.

Napoleon III, on being released by the Germans, withdrew to England and lived in Camden Place, Chislehurst. Later, he projected a return to France, in the hope that his presence would lead to a rising for his restoration to the throne; but the preliminary operation that he underwent to cure his incapacitating disease was unsuccessful. He died at Chislehurst on Jan. 9, 1873; and the early death of his only son, Napoleon Eugène Louis, prince imperial (1856–79), deprived Bonapartism of whatever chance it had of returning victorious to France.

One of the most enigmatic and controversial rulers of the 19th century, Napoleon III was long regarded as a mere tyrant or adventurer, an impostor with good intentions, perhaps, but with none of Napoleon I's outstanding ability. Later, however, when the personal animosities aroused by his reign had died down, his political significance and achievement could be better appreciated. His writings were published in collected editions, four volumes (1854–56) and five volumes (1856–69), supplemented by his *Histoire de Jules César*, three volumes (1865–66), and by the *Oeuvres posthumes* (1873).

NAPOLEON, a round game of cards (known colloquially as "nap"). Any number may play. The cards rank as at whist, and five are dealt to each player. The deal being completed, the player to the dealer's left looks at his hand and declares how many tricks he would play to win against all the rest, the usual rule being that more than one must be declared; in default of declaring he says "I pass," and the next player has a similar option of either declaring to make more tricks or passing, and so on all round. A declaration of five tricks is called "going nap." The player who declares to make most has to try to make them, and the others, but without consultation, to prevent him. The declaring hand has the first lead, and the first card he leads makes the trump suit. The players, in rotation, must follow suit if able.

If the declarer succeeds in making at least the number of tricks he stood for he wins whatever stakes are played for; if not he loses. If the player declaring nap wins he receives double stakes all round; if he loses he only pays single stakes all round. Sometimes, however, a player is allowed to go "Wellington" over "nap," and even "Blücher" over "Wellington." In these cases the caller of "Wellington" wins four times the stake and loses twice the stake, the caller of "Blücher" receives six times and loses three times the stake. Sometimes a player is allowed to declare *misère, i.e.*, no tricks. This ranks, as a declaration, between three and four, but the player pays a double stake on three, if he wins a trick, and receives a single on three if he takes none.

NAPOLEONIC WARS. An account of the wars of the European powers between 1792 and Nov. 1799, when Napoleon Bonaparte overthrew the Directory and assumed control of French affairs, will be found under FRENCH REVOLUTIONARY WARS. The present article is concerned with the warfare that continued, except during the uneasy peace of Amiens (1802–03), till Napoleon's first abdication (1814) and is arranged as follows:

When the *coup d'état* of Brumaire (Nov. 1799) brought Napoleon Bonaparte to power, the second coalition against France was beginning to break up. In Holland, a capitulation had been signed for the withdrawal of the Anglo-Russian expeditionary force; and though the Russo-Austrian forces in Italy had won a series of victories, the course of the campaign in Switzerland had reflected growing differences between Austria and Russia. Yet despite Russia's subsequent abandonment of the common cause and France's recovery of control over Holland and Switzerland, the British government paid no serious attention to Bonaparte's proposals for peace in Dec. 1799, since on the one hand the regime in France had yet to prove itself and on the other it was expected that the Austrians would make further gains.

I. THE DEFEAT OF AUSTRIA, 1800–01

Though Bonaparte had to embark on the campaigns of 1800 with inadequate forces and funds, the weaknesses of allied strategy went far to offset the disadvantages under which he laboured. Austria had decided on an equal division of its strength by maintaining armies of approximately 100,000 men in both the German and Italian theatres. Instead of reinforcing Austrian strength in northern Italy, where there was most hope of success, the British government spent its efforts in limited and isolated enterprises, among them an expedition of 6,000 men to capture Belle-Île and another of 5,000 to join the 6,000 already in Minorca. When in June these two forces were diverted to co-operate with the Austrians they arrived off the Italian coast too late to be of use.

Bonaparte's plan was to treat Italy as a secondary theatre and to seek a decisive victory in Germany. It proved impossible to increase Moreau's army of the Rhine to more than 120,000, too small a margin of superiority to guarantee the success required. Nevertheless, Bonaparte was busy with the creation of an army of reserve which was to be concentrated around Dijon and was destined to act under his command in Italy: until he had engaged this force in the south he would be able, should the need arise, to take it to Moreau's assistance. In Italy, Masséna's 30,000–40,000 outnumbered troops were to receive the Austrians in the Apennines and in Alpes-Maritimes until the army of reserve, marching to the south of the army of the Rhine, should cross the Alps, fall upon the Austrians' lines of communication, cut off their retreat from Piedmont and bring them to battle. Bonaparte had hoped that Moreau would mass the army of the Rhine in Switzerland and cross the river at Schaffhausen to turn the Austrian left in strength and obtain a decisive victory before dispatching some of his army to join the force descending on the rear of the Austrians in Italy. Moreau, however, preferred to think in terms of crossing the Rhine at intervals over a distance of 60 mi. and encountering the Austrians before he had concentrated his own forces.

1. The Marengo Campaign.—Moreau did not begin his offensive until April 25, 1800, when Bonaparte was issuing the preliminary orders for the crossing of the Alps by the army of reserve. The urgency of the situation in the south, where Masséna was besieged in Genoa on April 21 and L. G. Suchet had fallen back to the line of the Var, made it necessary to send the army of reserve, now en route for Geneva, over a pass further to the west than had been originally intended. An ill-provisioned force of 35,000 men and 40 cannon began the passage of the Great St. Bernard on the night of May 14–15 and completed it on May 25. Moreau, who had been asked to send 25,000 men via the St. Gotthard, released 15,000, but only 10,000 of them joined Bonaparte's army on June 1, a day before the French occupied Milan and its extensive magazines. When Masséna surrendered Genoa on June 4 and sent his forces to join Suchet's, Bonaparte's presence in the rear of the Austrians had robbed their success of significance. The collapse of the Austrian offensive enabled Suchet's troops to inflict serious losses in what fast became the Austrian rear as Michael Melas turned to meet the army of reserve. A number of oversights in the execution of Bonaparte's fundamentally sound strategy just before the battle of Marengo on June 14 came close to causing his destruction, for they enabled Melas to concentrate 30,000 men and more than 100 guns for an attack on Bonaparte's 22,000 and 14 guns. Bonaparte had had to yield ground when Desaix, responding to a hurried summons, returned to assault the Austrian vanguard with 6,000 men and 6 or 8 cannon. F. É. Kellermann's cavalry charge against the Austrian flank completed the transformation of near defeat into a victory, but Desaix was killed. (*See* MARENGO, BATTLE OF.)

On June 15, 1800, Melas concluded a capitulation: the Austrians were to evacuate northern Italy west of the Mincio, though remaining in Tuscany and the papal Legations; they received free passage of their troops to Mantua. While Bonaparte lacked the strength in Italy to impose more stringent terms, the Holy Roman emperor Francis II contracted a fresh agreement with Great Britain on June 20. Malta, which Bonaparte had offered to the Russian emperor Paul I three months before, fell to the British in September.

2. The Danube Campaign and Hohenlinden.—Moreau's principal columns, having reached the Rhine at Strasbourg, Breisach and Basel and completed the crossing on May 1, 1800, advanced along the south bank of the Danube. On May 3, C. J. Lecourbe took Stockach, while Moreau defeated Paul Kray at Engen. After a further reverse at Messkirch, the Austrians withdrew, to reach Ulm on May 11. Having lost his advantage in numbers at this point through the dispatch of the contingent to Italy, Moreau rejected a direct attack on the strong positions at Ulm in favour of a turning movement on the right. On June 19 he forced the passage of the Danube between Höchstädt and Donauwörth, thereby compelling Kray to evacuate Ulm. The French entered Munich nine days later and had pushed Kray's demoralized army back upon the Inn before hostilities were suspended, on July 15, by the armistice of Parsdorf.

At the end of the armistice both sides had armies of approximately 100,000 between the Danube and the Tirol. While a Franco-Dutch force of 16,000 from the Main protected Moreau's left wing, 20,000 Austrians in the Tirol covered his opponent's left flank. The Austrians forestalled Moreau's impending offensive on the Inn by launching theirs on Nov. 27, 1800. Moreau withdrew to muster his dispersed forces to meet an attempt to outflank him, and in the battle of Hohenlinden (Dec. 3) the mobility of the French enabled him to rout the Austrian columns, which lost 14,000 men and 80 cannon. Many thousands more were taken prisoner in a vigorous pursuit. By the armistice of Steyr (Dec. 25) the Austrians agreed to negotiate for peace without Great Britain.

In Italy the French, in contravention of the armistice, had occupied Tuscany in Oct. 1800 on the grounds of British activity at Livorno. On the Mincio front Macdonald arrived from Chur (by a bold crossing of the Splügen pass) with 14,000 men to strengthen Brune, who then forced the crossing against the outnumbered Austrians late in December. Having abandoned the Adige (Jan. 1, 1801) and the Brenta (Jan. 11), the Austrians were ready to sign the armistice of Treviso (Jan. 15).

3. The Peace of Lunéville and the Italian Settlement.—The Franco-Austrian peace of Lunéville was signed on Feb. 9, 1801. For the most part it repeated the treaty of Campo Formio (1797). The French frontier was to be advanced to the Rhine, with the proviso that the rulers thus dispossessed should be compensated from ecclesiastical territory in Germany; compensation was also to be found for the Habsburg grand duke Ferdinand III of Tuscany, who was also to be dispossessed; and the Dutch, Helvetic, Cisalpine and Ligurian republics were recognized by Austria.

The Neapolitans, who had meanwhile invaded Tuscany, were driven back by Murat's force of 26,000; and the armistice of Foligno (Feb. 18, 1801), whereby they agreed to evacuate the papal states, was followed by the peace of Florence (March 28), whereby Naples lost little territory but undertook to exclude British and Turkish trade. In accordance with the treaty of Aranjuez of March 21, 1801, between Bonaparte and Charles IV of Spain (who in Oct. 1800 had restored Louisiana to France), Tuscany was erected into the kingdom of Etruria for Charles IV's son-in-law, Louis of Bourbon-Parma; and Parma, to which the latter renounced his claim as heir apparent, passed under French administration. Abandoned by the Austrians, Charles Emmanuel IV of Sardinia could do nothing against the continuing French occupation of Piedmont.

II. GREAT BRITAIN, FRANCE AND THE NEUTRALS, 1800–02

The British, in pursuit of their primarily maritime, colonial and commercial interests in the wars, might claim to be serving the common cause and had moreover applied their profits to subsidizing the continental armies, but had adopted means that offended neutral states and former allies alike. Through the blockade, the British could virtually dictate the terms of European sea trade: granting licences for merchant shipping to enter the ports of France and France's associates, they admitted neutrals only when there were not enough British ships to carry all the colonial produce of which they now controlled the sources. Moreover, the British maintained that a neutral flag did not cover an enemy's goods; that these might be seized when destined for a port only blockaded on paper; that iron, hemp, timber, pitch and corn were at all times contraband of war; and that neutral ships were liable to search even when under convoy.

1. The League of Armed Neutrality.—Offended by the British capture of Malta after Bonaparte had presented the island to him, the Russian emperor Paul, in Nov. 1800 placed an embargo on British ships in Russian ports; and on Dec. 16 Russia, Sweden and Denmark renewed that League of Armed Neutrality which they had first made in 1780, during the American Revolution. The Danes occupied Hamburg, which had become the main entrepôt for Anglo-German trade after the French invasion of Holland, while the Prussians, who joined the league on Dec. 18, invaded Hanover.

Germany and the Baltic had witnessed much of the expansion of British trade during the previous decade of war, British exports to Bremen and Hamburg having risen 600% between 1792 and 1800. The closing of the Baltic and of the German ports and rivers thus struck the most damaging blow at Great Britain's commerce and war economy. Furthermore, the Baltic and Germany also supplied most of the materials for British shipbuilding and were the main source of the imports of grain, supplying 5%–16% of British consumption. As the harvests of 1799 and 1800 were poor, the interruption in shipments was soon felt in a bread shortage.

The assassination of the emperor Paul (March 1801) removed the chief author of the league at a moment when its members had to reckon with British reprisals. A fleet including 18 ships of the line under Sir Hyde Parker had left Yarmouth for the Baltic on March 12; and on April 2 Nelson led a vanguard of 12 battleships and the frigates into Copenhagen harbour. The shore batteries opened fire; but, despite orders to retire and the grounding of three battleships, he continued the action till he had overcome the stubborn resistance of the vessels and hulks anchored there. The Danes agreed to an armistice and made peace on May 28; Sweden had already done so on May 18, and an Anglo-Russian convention followed on June 17. The league was thus dissolved and its forces withdrawn from Hanover, Hamburg and Lübeck; in return the British modified their maritime claims. The new Russian emperor, Alexander I, moreover gave up the demand for Malta.

2. The Anglo-Turkish Conquest of Egypt.—British sea power made possible a further success in the course of the year 1801: the defeat of the army that Bonaparte had left in Egypt in 1799. An expeditionary force of 18,000 under Sir Ralph Abercromby was landed at Aboukir (Abu Qir) in March, the Turks sent 25,000 to the theatre, 6,000 sepoys from India arrived via the Red sea, and the 13,000 French in Cairo surrendered on June 28 and the 5,000 in Alexandria on Aug. 30. Nelson's attack on the flotilla at Boulogne, however, met with failure (Aug. 15–16).

III. THE INTERVAL OF PEACE, 1802–03

Meanwhile the British economy was suffering from severe strain. Gold payments rose steeply in 1800 and 1801, for in addition to disbursing £5,600,000 in subsidies and £2,800,000 in their own military expenses in Europe during these two years, the British spent an estimated £19,000,000 on grain imports, though only once since 1793 had these last exceeded £2,000,000 per annum. The price of wheat had risen to 156*s.* per quarter by March 1, 1801. It fell to 129*s.* in June and to 75*s.* in December.

1. The Peace of Amiens.—The British government had opened negotiations with France on Feb. 21, 1801. Pitt, whose place as prime minister had been taken by Henry Addington, approved of this overture not so much because of the collapse of Austria as because of the danger presented by the League of Armed Neutrality. The preliminaries having been concluded on Oct. 1, 1801, the peace of Amiens was signed on March 27, 1802. Notwithstanding their reverses overseas, the French recovered all their colonies. The British kept Ceylon (taken from the Dutch) and Trinidad (taken from the Spaniards), but restored Minorca to Spain and Cochin, the Cape of Good Hope and the Spice islands (Moluccas) to Holland. France agreed to the evacuation of Naples and the papal states and to the return of Egypt to Turkey. The British undertook to leave Malta within three months: the island was to be handed back to the Order of St. John of Jerusalem, and until the Order could assume its government was to be garrisoned by 2,000 Neapolitan troops, with its neutrality guaranteed by the powers. It was agreed that "an adequate compensation" should be found in Germany for the prince of Orange, William V, who had lost his position in the Netherlands. Though Bonaparte had already ignored his undertaking in the treaty of Lunéville to observe the independence of the neighbouring republics, the treaty of Amiens made no reference to nonintervention in their affairs; and when later the British government complained that French troops remained in Holland and northern Italy in violation of the treaty of Lunéville, Bonaparte replied that this was the business of the signatories to that treaty and that he desired "the treaty of Amiens and nothing but that." France had asked for British recognition of the Italian republics, but in the absence of compensation for the king of Sardinia this was withheld.

2. Redispositions in Europe.—Representatives of the Cisalpine republic, summoned to Lyons at the end of 1801 to remodel their constitution, invited Bonaparte in Jan. 1802 to accept the presidency of the republic, which was henceforth to be known as the Italian republic. Similar arrangements were subsequently made in the Ligurian republic and in Lucca; and Piedmont was brought under direct French rule in Sept. 1802.

In Germany the compensation of the rulers dispossessed by the French was settled by the *Reichsdeputationshauptanschluss* of Feb. 1803. French and, to a lesser extent, Russian influence marked the negotiations by which the ecclesiastical principalities and all but six of the imperial cities were distributed among the displaced princes and the larger German states. The church in Germany lost nearly 2,500,000 subjects; Prussia gained nearly 400,000; Bavaria's losses on the left bank of the Rhine were more than compensated by the acquisition of bishoprics and imperial cities to the east; Württemberg, Baden, Hesse-Kassel and Salzburg became electorates. Austria gained some territory but was in effect weakened, since the new settlement not only left the *Reich* feebler but also lessened the emperor's voice in its affairs.

The coming of peace accelerated Bonaparte's reorganization of French institutions and overhaul of governmental machinery; and his achievement in this field provided the model for countries under French occupation during the following decade.

IV. ECONOMIC ASPECTS OF THE WARS

France had a population of 27,350,000 in 1801 as opposed to Great Britain's 10,942,146 and had gained much territory in the warfare since 1792; but a significant advance in economic strength was to enable Great Britain to wage war against this formidable adversary and to achieve the "miracles of credit" whereby foreign military assistance could be subsidized. The French, whose manufactures progressed less dramatically than the British and whose seaborne trade had been strangled, found it impossible to raise funds commensurate with their aggressive policy in Europe, so that Napoleon had to rely on the spoils of conquest to supplement the deficiencies of French finance.

Many of the figures for British overseas trade during the period represent official values based on a scale of prices current in the 1690s, regardless of market value. Useful only for comparison, the official scale shows that exports rose from £20,000,000 in 1790 to £53,500,000 in 1814, increasing by 75% between 1790 and 1801 and by 51% between 1801 and 1814. The total expendi-

ture of the British government in 1793 was £30,590,000, of which war services amounted to £10,340,000 (nearly twice the figure for peacetime); in 1814 these sums had increased to £163,790,000 and £69,070,000 respectively. The steep rise in national income made this possible both by providing immediate revenue and by supplying the funds from which investors lent to the state, whose debts rose from £230,000,000 at the beginning of 1793 to £507,000,000 in 1802 and to £900,000,000 in 1815. For the period as a whole, 35% of the addition to the country's expenditure caused by the war was met from current revenue, and between 1802 and 1813 the proportion of total net governmental income derived from borrowing was never more than 54.7%.

Great Britain had superior banking services, could suspend payments in gold at home and raise heavy loans and was preponderant in the European money market. France by contrast was financially hampered by a national economy and financial machinery ill-constituted to produce government credit, by the virtual impossibility of inflating the metallic currency and by potential investors' lack of confidence in the regime. The deliberate obscurity of Napoleon's budgetary system makes it difficult to ascertain the exact state of government finances. Among the privy funds that he amassed were (1) the *trésor de l'armée*, formed by Austrian and Prussian war contributions and estimated to have furnished 743,000,000 francs between 1805 and 1810; and (2) the *domaine extraordinaire* of Jan. 1810, largely composed of the territories which Napoleon had retained in the satellite states. These hidden sources of income met some part of French expenditure, and foreign states made further contributions of money as well as troops and supplies, but the disparity between French and British financial resources remains clear. In 1813, when French expenditure was in the region of £40,000,000, the British government was able to borrow £105,000,000 of the £174,000,000 that it spent.

Napoleon's economic ideas owed much to the outmoded mercantilist school. He hoped to destroy Great Britain's capacity to make war by closing the European markets to British trade. Yet when at last he was in a position to do so the military strength whereby he had enforced his will on Europe was so strained that the continental powers could break the boycott prematurely and resume hostilities against his widely dispersed armies.

Imported grain provided no more than 5% of Great Britain's consumption in normal years and is estimated never to have exceeded 16%, though in such periods as 1800–01 and 1811–12 home production of grain fell short of normal demand by 40%. There is no evidence that Napoleon ever considered withholding grain from Great Britain in an attempt to force withdrawal from the war: when he did suspend shipments, as in 1811–12, it was because grain was scarce in Europe. At other times his mercantilist views led him to export French grain to Great Britain, provided that France received cash, not goods, in return.

For the mercantile marine France had had more than 2,000 ships employed in European and colonial trade by 1792 but possessed only 200 ships of 200 tons or more by 1800, while British strength rose by one-third in ten years to number 19,772 vessels (2,037,000 tons) in 1802 and was to reach 21,869 ships (2,447,831 tons) in 1815. Maritime supremacy enabled the British to dominate the colonial reexport trade (coffee, tea, sugar, spices, cotton and dyes) to the great advantage of their national economy.

V. FRENCH AND BRITISH ARMED FORCES

1. Napoleon's Army and Method of Warfare.—In France the law of 10 Fructidor year VI (Sept. 5, 1798), had replaced the levies of the Revolution by a regular method of conscription which, with a few modifications, remained in force until 1815. Of the 5,692,164 men belonging to the 18 classes affected by this law, 2,716,567 were called up and 2,022,201 actually incorporated in the army. Troops levied in the 12 years 1800–11, of whom slightly more than 75% came from areas French in 1792, accounted for no more than 50% of those mobilized between 1798 and 1815.

Between the peace of Lunéville and the campaign of 1805 Napoleon formed the best of the armies that he was to lead: approximately half of its effectives had already seen active service; and there had been ample opportunity to absorb recruits into it and to accustom it to maneuvers en masse. No changes were made in tactics or battle formation (the infantry continued to use the *règlement* of 1791): it was by the overall organization of his army and the direction of its movements that Napoleon brought a new form to warfare with the campaign in 1805, in which for the first time 200,000 men employed in divisions and corps were coordinated to a single purpose under one leader. In 1800 the practice had been adopted of forming groups of several divisions under the command of a senior general, but it was with the formation of the *armée des Côtes*, or Coastal army, on the Channel coast that Napoleon introduced the army corps as the definitive basis of army organization. Each corps was given a separate staff and administrative services and was composed ordinarily of three infantry divisions and a division of light cavalry. Separate from the army corps was the cavalry reserve of two divisions of cuirassiers (heavy cavalry) and three or four divisions of dragoons, each with a mobile battery of horse artillery.

The organization of an appropriate general staff, transport, artillery and rear services was also undertaken. Napoleon's possession of a general staff, however, did not imply the circumstances associated with the term in later usage. Its chief, Berthier, and the rest of its personnel were required not to think or to act independently but to communicate effectively between Napoleon and his corps commanders. There was no real training for staff work, and the staff officers were chosen haphazardly, as Napoleon reserved the control of a campaign to himself (though he allowed his corps commanders much freedom in the execution of his orders). He was content to employ largely second-rate men who were not always adequate to the parts allotted to them under his supervision and who were to show still more serious deficiencies when they became theatre commanders.

Since he lacked the means to provide for more systematic methods, Napoleon's campaigns had to yield prompt and decisive results. The virtual abandonment of traditional lines of communication in favour of an independent "line of operations" directed against the enemy army and based on a convenient centre for immediate rear services, together with the reduction of supply trains to a minimum, conferred great strategic benefits so long as victory was soon obtained. The system, however, was not amenable to prolonged campaigning or to the conduct of a successful retreat, in which the army would quickly exhaust its supplies, since its customary measures of pillage and forced requisition were less efficient than the more normal organized raising of supplies for payment. Nor could the system be easily applied in comparatively unproductive areas or over great distances: perfected in western Europe and in northern Italy, it was far less practicable in the east.

Napoleon did not prescribe the infantry formations to be used by his corps commanders, whose varying combinations were often ineffective and wasteful of manpower, especially in the frontal attacks that he favoured in his later battles. He made no attempt of any consequence to introduce the two-rank firing that the British used to such advantage against opponents whose ranks were at least three deep. He put great emphasis on his cavalry, which screened the movements of army corps, intervened at crucial moments in battle and conducted the vigorous pursuits so profitable after a victorious engagement. With a remarkable grasp of the strategic implications of a situation, Napoleon was preeminent in disposing his army corps to discover the whereabouts of enemy forces, to head them off from retreat, to obstruct their concentration and to bring them to battle. Mobility and the careful dispersal of semi-independent army corps so as to control an extensive area were often decisive factors in Napoleon's campaigns.

2. British Military and Naval Strength.—The British regular army had been employed predominantly in colonial warfare, for which it had been freed by calling up the militia to supplement home defense; but even so the demand for men had outrun the supply of volunteers, and in July 1799 the government had begun paying a bounty to militiamen who would volunteer for service with the regular army. The strength of the latter was reduced to 95,800 after the peace of Amiens. Inevitably the British attached primary importance to their navy. In 1803, whereas the

French had 23 ships of the line and 25 frigates and could call upon the Dutch republic's 15 capital ships (of which, however, only 5 were in commission), the British had 34 ships of the line and 86 frigates in service and 77 of the line and 49 frigates in reserve; and at the close of the war the British had 240 ships of the line and 317 frigates against the French 103 and 55.

VI. THE THIRD AND FOURTH COALITIONS, 1803–07

1. The British Rupture of the Peace.—Among the causes of the rupture of the peace of Amiens was Napoleon's refusal to make a trade treaty with Great Britain. Excluded from France and the countries under French control, the British merchants and manufacturers found peace no more profitable than war. The British government, having shown its good faith by abolishing the wartime income tax and by considerably reducing naval and military expenditure, found ample pretexts for dissatisfaction in Napoleon's uncompromising treatment of the dependent territories; and the provocative report by Gen. H. F. B. Sébastiani, published in the *Moniteur* of Jan. 30, 1803, which declared that 6,000 men could reconquer Egypt, gave fresh cause for dispute. Claiming that the treaty of Amiens was not being carried out, Addington's government decided to retain Malta in defiance of the treaty, thus supplying the technical *casus belli*. To obtain an initial advantage, Great Britain declared war on May 18, 1803.

The French thereupon occupied Hanover and Naples, closing Hamburg and Bremen to British trade but failing to occupy Sicily. Both Hanover and Naples, together with Holland, were charged with the support of their French garrisons, 78,000 strong. The French treasury drew on the revenues of northern Italy, received yearly subsidies of 84,000,000 francs from Spain and Portugal and obtained $11,250,000 outright from the sale of Louisiana to the United States in May 1803. Spanish subsidies to France led Great Britain in Oct. 1804 to seize bullion ships en route for Spain, thus provoking the hostilities which lasted until 1808.

At the end of 1803 Napoleon gave the title *armée d'Angleterre*, or army of England, to his forces assembled around Boulogne. Later, when he had successfully turned this army against the continental powers, he could claim that such had been his original purpose. He had, however, made extensive preparations for the invasion of England, and the army maintained on the Channel coast numbered more than 100,000. At first he envisaged a crossing of the Channel en masse, to be completed before British naval forces had time to intervene against his lightly armed invasion craft; but it soon became apparent that there could be no question of getting the invasion fleet to sea quickly enough for that. The Channel therefore had first to be cleared of British warships, and Napoleon prescribed a policy for the French fleet which he hoped would draw British naval strength away from home waters.

2. The Formation of the Third Coalition.—Napoleon seems not to have felt apprehensive at the prospect of a third coalition against France, for he pursued courses which could only encourage its formation. In June 1804, shortly after Pitt had replaced Addington, the British government, which had been considering the terms on which to seek an alliance with Russia and Sweden, received proposals for an Anglo-Russian agreement. Austria could at first respond to Russian overtures only by accepting the promise (Nov. 1804) of Russian help against a French attack; Sweden signed an alliance with Great Britain in Dec. 1804 and with Russia early in 1805; but it was not until April 11, 1805, that Great Britain and Russia provisionally concluded a treaty envisaging a European league to compel France to evacuate Italy and Hanover, to restore independence to Holland and Switzerland and to reinstate the king of Sardinia in Piedmont. The British offered an annual subsidy of £1,250,000 for every 100,000 troops that their allies employed in the field.

The French empire had been proclaimed in May 1804 and Napoleon had been crowned emperor in December. He had next accepted the transformation of the Italian republic into the kingdom of Italy, with himself as king, in March 1805; and soon afterward Liguria was annexed to the French empire. The Holy Roman emperor Francis II, who in view of the diminution of Habsburg influence in Germany had already assumed the additional style of emperor of Austria, as Francis I, in Aug. 1804, was now so much affronted by Napoleon's actions in Italy that on Aug. 9, 1805, he adhered to the Anglo-Russian alliance, which had been finally ratified on July 28.

Napoleon was not without support against this coalition: Bavaria (which joined France on Aug. 25, 1805), Baden (Sept. 5) and Württemberg (Oct. 5) were normally opposed to Austria, and their desire to absorb adjacent Habsburg domains encouraged them to range themselves with France. Moreover, Prussia's neutrality favoured the French by blocking the route that a Russo-Swedish force, accompanied by a British contingent, could have taken from Stralsund to attack the French in northern Germany and the Netherlands; and Prussian coolness toward the coalition later delayed the march of Russian armies to support the Austrians in Bavaria.

3. Ulm, Austerlitz and the Peace of Pressburg.—The Austrians, who had hesitated to join the coalition, now rushed into hostilities with such speed that they enabled Napoleon to deal with their main army before the Russians had come to their support. Employing heavily superior forces under the archduke Charles in northern Italy against Masséna (who was to conduct a defensive campaign on the Adige) and keeping a further 25,000 under the archduke John in the Tirol, they prejudiced their chance of success in the main theatre of war, Bavaria. On Sept. 8, 1805, fewer than 80,000 Austrians under Karl Mack crossed the Inn, whereupon the much smaller Bavarian army withdrew safely northward to Würzburg. Though Napoleon had begun to move 176,000 men toward central Europe in the last days of August, Mack did not even wait for the first Russian army to join him; and while respect for Prussia's neutrality delayed the arrival of the second Russian army till November, Bernadotte's Frenchmen from Hanover marched southward across Prussian Ansbach without Prussia's permission.

Napoleon's first orders had directed the French forces in Hanover on Würzburg, Marmont's corps in Holland on Mainz and the army of England, henceforth renamed the Grande Armée, on lower Alsace; but when he learned that Mack was in the Black Forest, he swung his own army to its left, reaching the Rhine in the former Palatinate and passing through Württemberg and Franconia in columns which converged on Mack's rear. Mack had grouped his forces around Ulm and awoke too late to his danger. Napoleon's forces began crossing the Danube around Donauwörth, 50 mi. downstream from Ulm, on Oct. 7, 1805. Uncertain of the Austrians' latest positions, Napoleon now extended his front along the Lech river, detaching one corps toward Munich to contain the Russians should they appear. Despite bad weather, shortage of supplies and clumsiness on the part of some of Napoleon's subordinates in the course of Mack's encirclement, the mass of Mack's army was taken prisoner at or soon after his capitulation at Ulm, concluded on Oct. 20. So vigorous was the pursuit of the escaping units of Austrians that only one division joined the Russians under Kutuzov, who reached the Inn in mid-October with fewer than 40,000 men and who now retired as Napoleon advanced. Leaving Ney to drive the archduke John from the Tirol, Napoleon entered Vienna on Nov. 13. The archduke Charles, having gained some ground on Masséna in Italy, was recalled to Austria, but came too late to defend Vienna and withdrew into Hungary.

Murat had gained the passage of the Danube near Vienna by a subterfuge, and the French continued to pursue the Russians, who fell back to Olmütz (Olomouc). Napoleon was constrained to suspend his advance at Brünn (Brno), since Kutuzov had been joined by the second Russian army. Moreover, Frederick William III of Prussia, indignant at Bernadotte's violation of Prussian neutrality, was now threatening to intervene in favour of the allies and could have settled the issue if he had promptly sent his army of 180,000 men into the struggle. Great Britain, however, had been offended at Prussia's desire to occupy Hanover and so had not offered money for Prussian or other North German forces; and British coolness, together with the influence of the pro-French party in Berlin and Napoleon's procrastination of discussions with the Prussian envoy, Christian Haugwitz, kept Prussia out of the

field while Napoleon settled accounts with Russia and Austria. In the battle of Austerlitz (*q.v.*), on Dec. 2, 1805, the allies lost approximately 26,000 of their 87,000 men and 180 guns, and the French between 7,000 and 8,000 of their 73,000 men. Francis of Austria signed an armistice with Napoleon on Dec. 6, and Alexander withdrew his broken army to Russia under a truce.

The peace treaty between France and Austria was signed at Pressburg (Bratislava) on Dec. 26, 1805. Austria had to cede Venetia, Istria and Dalmatia to Napoleon as king of Italy; Tirol, Vorarlberg and several smaller territories to Bavaria, whose elector, Maximilian Joseph, was now to be recognized as a king; and other territories to Württemberg and to Baden, which became a kingdom and a grand duchy respectively. Würzburg was ceded by Bavaria to Ferdinand of Salzburg (the former grand duke of Tuscany), who in turn ceded Salzburg to Francis of Austria.

4. Trafalgar and Italy.—The war at sea culminated in the battle of Trafalgar (*q.v.*), on Oct. 21, 1805. On Sept. 14, Napoleon had instructed Adm. de Villeneuve at Cadiz to enter the Mediterranean and to hold some of the coalition's forces in Italy by attacking Naples while the French army marched to the Danube. On Oct. 19–20, Villeneuve left harbour with 33 ships of the line, his Spanish vessels mingled with the French. Then Nelson came up with him off Cape Trafalgar, with 27 ships. The French and Spanish lost 19 ships on the day of the battle, and 4 more were captured early in November; the British lost none in the battle or in the storm which followed, sinking many of their prizes. Nelson and 448 British were killed; wounded brought their total casualties up to 1,690. French and Spanish casualties numbered about 4,400 killed, 2,500 wounded and 7,000 captured. The immediate result was to frustrate French plans for a diversion against Naples, and there could be no return to plans for an invasion of England.

The Anglo-Russian force that landed at Naples in Nov. 1805 arrived long after Napoleon had withdrawn his troops from the south to strengthen his defenses on the Mincio and too late to affect the outcome of the year's campaigns. The Neapolitans welcomed it and joined the coalition; but the French army forced the allies to withdraw to Corfu and to Sicily (though Reggio, on the mainland, remained in British hands till Feb. 17, 1808); and Napoleon's brother Joseph was proclaimed king of Naples on March 30, 1806, in place of the Bourbon Ferdinand IV (whose deposition Napoleon had announced in Dec. 1805). With the occupation of the papal states the whole of Italy was under French control.

5. Hanover and the Confederation of the Rhine.—In Vienna on Dec. 15, 1805, Napoleon and Haugwitz had drafted the treaty of Schönbrunn whereby Prussia was to enter into an offensive-defensive alliance with France, to cede Neuchâtel, Cleves and Ansbach and to acquire Hanover. The Prussian government, wishing simply to occupy Hanover till peace should have been made, did not ratify this treaty, but was soon forced, under the treaty of Paris (Feb. 15, 1806), to annex Hanover outright and to close the Prussian as well as the Hanoverian ports to British commerce. Great Britain consequently declared war on Prussia (April 21) and seized 250 Prussian ships in British harbours.

Having thus embroiled Prussia with Great Britain, Napoleon obstructed the plan for a confederation, under Prussian leadership, to include Saxony and other states of northern Germany. He set up his brother Louis, however, as king of Holland (June 1806) and then proceeded to form the Confederation of the Rhine in July, embracing Bavaria, Württemberg, Baden, Aschaffenburg, Hesse-Darmstadt, Nassau, Berg and several smaller states of western Germany, with himself as its protector. When these confederates announced that the ancient *Reich* had ceased to exist, Francis of Austria acquiesced by renouncing his title of Holy Roman emperor (Aug. 1806). Negotiations had meanwhile been proceeding between the belligerents, but Charles James Fox's ministry, which had taken office in Great Britain after Pitt's death (Jan. 1806), made no more progress with Napoleon than did the Russians.

6. The Russo-Prussian Alliance.—The hardening of anti-French feeling in Berlin put an end to an uneasy stalemate, and Russia and Prussia signed a secret defensive alliançe against France in July 1806. Napoleon, however, still discounted the notion that Prussia might go to war against him: he was preparing to honour his undertaking to withdraw French forces from Germany even when Prussia, on Aug. 9, had ordered partial mobilization. Growing tension in Prussia and the stronger tone of Russian diplomacy soon made him change his mind. On Sept. 5, 1806, a day before the Prussians opened the North Sea ports to the British, he instructed his forces in the triangle Coblenz, Constance and Passau to regroup farther north between Frankfurt and Amberg.

Prussia had chosen to go to war with France in far less favourable circumstances than those which had obtained in 1805: the French were now within easy reach of the frontier, the Austrians could no longer intervene, the Russians were behind the Vistula. Furthermore, the Prussian army had little light infantry, poor artillery and only cumbersome supply trains and had not yet adopted the divisional system. In the face of Napoleon's army corps, the Prussians took the field in three armies commanded by elderly men. The first and fundamental mistake of the Prussian high command was to come forward, instead of withdrawing to form a line along the Elbe and awaiting the arrival of the Russians.

7. The Campaign of Jena and Auerstädt.—Having won the support of the elector Frederick Augustus of Saxony, the Prussians marched into Saxon territory on Sept. 13, 1806. The news reached Paris five days later, and on Sept. 19 Napoleon ordered the concentration of the Grande Armée, by the beginning of October, along the Main as far as Bamberg and thence to the south. At Mainz on Sept. 29 he learned that the Prussians were still between Eisenach and Hildburghausen in front of the Thuringer Wald and roughly at right angles with the Main. This news suggested that he had time to enter Saxony so as to appear in the rear of their left flank. Having reached Würzburg on Oct. 2, he closed up his forces; and on Oct. 5 he gave orders for the march to the northeast: in three columns, his corps were to cross the Frankenwald and debouch on the upper Saale at Saalfeld, Schleiz and Hof. On Oct. 9 a Saxon division was attacked at Schleiz; on Oct. 10 a Prussian detachment was routed at Saalfeld; Hof was occupied without opposition. While Napoleon continued his advance toward Gera, the Prussian army under Prince Friedrich von Hohenlohe retired northward to Kahla, 20 mi. to the west of Napoleon's objective.

The engagement of Saalfeld at last convinced the Prussians that they might be cut off from the Elbe, and they decided to concentrate their forces, under King Frederick William and Charles William Ferdinand of Brunswick, at Weimar. When the French forces reached the Saale (Oct. 12, 1806), Napoleon ceased his march to the northeast and moved his forces to the left to close in on the river line. As Hohenlohe retreated from Kahla to Jena, Napoleon swung his right wing northwestward to gain the Saale and march up its right bank, while the main body of the French was directed to cross the river between Kahla and Jena and then to advance on the mass of the Prussian forces. By the evening of Oct. 12 Napoleon's main advance guard had made contact with the outposts left at Jena by Hohenlohe and Davout was at Naumburg, 20 mi. downstream, within easy reach of the roads from Weimar along the left bank of the Saale via Auerstädt and Freiburg toward the Elbe. The movements of the following day and the separate defeats of the Prussian forces on Oct. 14 are described in the articles JENA, BATTLE OF; AUERSTÄDT, BATTLE OF. The Prussians lost 22,000 killed and wounded in the two battles and 18,000 prisoners. The most famous pursuit of the Napoleonic period began on Oct. 15 and ended with the capitulation at Ratkau, near Lübeck, on Nov. 7, of Blücher's detachment. Of the Prussian army, only 15,000 men under Anton Wilhelm von Lestocq escaped to East Prussia. Together with 120,000 prisoners, vast quantities of matériel had been taken: one month's campaigning had destroyed the Prussian war machine.

The price of such defeat was severe. Pending the final settlement a war contribution of 160,000,000 fr. and extensive requisitions throughout northern Germany were exacted. Napoleon's immediate demands were for all Prussian territory west of the Elbe except Magdeburg and the Altmark, but the rapid collapse of Prus-

sia, the Russian advance into Prussian Poland (Oct. 23, 1806) and the disclosure of the Russo-Prussian alliance soon led him to offer an armistice instead of a peace treaty. On Nov. 10 he announced that he would occupy Berlin until a general settlement had been made, including the restoration by the British of the colonies seized from the French and their allies. Frederick William preferred to remain in the allied camp. Meanwhile the French had occupied Brunswick and Hesse-Kassel; and Würzburg had joined the Confederation of the Rhine in September. The peace of Posen (Poznan), between France and Saxony was concluded on Dec. 11, 1806, bringing Saxony into the Confederation of the Rhine and giving its elector, Frederick Augustus, the title of king.

8. The Winter Campaign of 1806–07: Eylau.—From Berlin the French advanced into Poland. Behind the Vistula were Lestocq's Prussians and 55,000 Russians under Bennigsen, who had occupied Warsaw and the right bank and was awaiting a further Russian army of 35,000 men under F. W. von Buxhöwden. On Nov. 28, 1806, Bennigsen abandoned Warsaw without resistance to Murat, whom Napoleon had sent ahead with Davout, followed by Lannes and Augereau. As the three remaining French corps became available, Napoleon directed Ney's and Bernadotte's toward Thorn (Torún) and Soult's between Thorn and Warsaw. At Berlin, on Nov. 19, Napoleon had informed a Polish deputation that he sympathized with their desire for the restoration of Poland; but though he was ready to recruit Polish assistance, he did not contemplate a thoroughgoing revival of the Polish state, which would have aroused further Russian enmity and Austrian opposition.

Bennigsen withdrew his forces to the Narew, principally around Pultusk, and was reinforced by Buxhöwden. On Dec. 18, 1806, Napoleon himself reached Warsaw. After some indecisive engagements between Dec. 22 and Dec. 29 he gave up all hope of an effective pursuit of the retreating Russians and ordered his army into winter quarters. The combined Russian and Prussian forces had numbered about 115,000, of whom about 20,000 had been killed, wounded and captured; the French had suffered approximately 5,000 casualties. Weather, terrain and poor communications robbed the French of their mobility and Napoleon was handicapped by the unfamiliar difficulty of feeding an army in an unfertile area whose resources the Russians had already exhausted.

Most of the French army was grouped in front of Warsaw. On the extreme left one corps was placed before Elbing (Elblag); another at Neidenburg (Nidzica) linked the force at Elbing with the mass of the army; and outposts were established along the Passarge (Pasleka), then along the Omulew and as far south as the Bug. Ney, who had been ordered to push the Prussians northward late in Dec. 1806, so exceeded his instructions that his troops had not reached winter quarters when Bennigsen advanced against the French left wing in the last days of Jan. 1807. On Jan. 25 Bernadotte concentrated his corps at Mohrungen (Morag), 8 mi. W. of the Passarge, where he repulsed the numerically superior Russian advance guard before withdrawing southward toward Osterode (Ostroda). Anxious to appear in the rear of his enemy, Napoleon marched northward along the right bank of the Alle (Lyna) with three corps. He came up with the Russians, who had retreated to the north between the Passarge and the Alle, at Göttkendorf (Gutkowo) on Feb. 3, but night fell before a battle could be fought, and by morning the Russians had decamped, abandoning their magazines on the Alle. The French continued their pursuit, and on Feb. 7 their forward troops attacked the Russian rearguard outside Eylau, occupying the town that night. The battle of Eylau was fought on the following day, Feb. 8, 1807. The Russians suffered 25,000 casualties and were able to retreat in good order; the French, having had 28,000 casualties and being unable to pursue the Russians, fell back into winter quarters along the Passarge.

9. Great Britain and the Fourth Coalition.—Though he had more than 600,000 men under arms in Europe altogether, Napoleon had barely 150,000 available for the war in East Prussia, and of those only 100,000 could be used for the decisive operations of summer 1807 (50,000 remained in Poland, protecting lines of communications and covering the 30,000 Russians disposed along the Narew). To the north, in East Prussia, there were 24,000 Prussians and 85,000 Russians by June 1807, and more Russian troops were expected. The allies, however, were not well placed to profit from the dispersal of Napoleon's forces. While Russia was handicapped by having undertaken war against Persia (1804) and Turkey (1806), Great Britain's practice of piecemeal warfare overseas precluded the dispatch of a strong expedition to help the eastern allies.

The progress of the campaign in East Prussia was obscured for the British by developments in South America. On June 27, 1806, a squadron under Sir Home Popham, with 1,600 troops, had captured Buenos Aires; and though the Spaniards had recovered the place in August the prospect of opening up new markets was so attractive to the British that a second expedition of 7,800 men under Sir John Whitelocke was sent out. Landing near Buenos Aires on June 28, 1807, it suffered such heavy losses in the assault on the city's defenses that the project had to be abandoned. Failure had also overtaken the 6,000 troops sent from Sicily to Alexandria in March and the naval squadron dispatched in February to assist the Russians by attacking Constantinople.

It was not until April 26, 1807, that Russia and Prussia concluded the convention of Bartenstein (Bartoszyce), by which they undertook to make no separate peace treaties and to free Germany and Italy. The British proposed to grant Prussia a subsidy of £1,000,000 and to send an expeditionary force to Stralsund to join 16,000 Swedes in opposing the French, who had occupied Swedish Pomerania. Sweden, however, had signed an armistice with the French on April 18, and this truce lasted till July 3. When 8,000 British troops under W. S. Cathcart disembarked at Rügen in mid-July, the Russians and Prussians, farther to the east, had already been defeated. The fourth coalition had come into being too late.

10. Friedland.—Soon after the suspension of the winter campaign, Napoleon issued orders for the siege of Danzig. The investment began on March 12, 1807, and the town was surrendered on May 26, offering a valuable base for operations. The French army had left winter quarters early in May to assemble behind the Passarge. On June 5 the Russians appeared before the French left wing. As Bennigsen's opening moves traversed the French front, Napoleon grouped his forces.

On June 8, 1807, an encounter with 10,000 Russians suggested that the mass of the Russian army was around Guttstadt (Dobre Miasto), on which Napoleon proceeded to march and where on June 9 he dislodged the Russian rearguard. The Russians retreated to Heilsberg (Lidzbark Warminski) on the Alle, where they had prepared an entrenched camp, 35 mi. S. of Königsberg and 27 mi. S. W. of Friedland. Heavy fighting took place before Heilsberg on June 10, in which the French had the advantage. Next day Napoleon brought up the rest of his forces, trusting that the threat to their lines of retreat would make the Russians withdraw—as they did late in the evening. Bennigsen crossed to the right bank of the Alle, while Napoleon, anticipating that he would soon reappear on the left bank, headed north toward Eylau to place himself between the Russians on the Alle and the Prussians in front of Königsberg. On June 13 the French were massed close to Eylau, with strong detachments pushed forward in the direction of both Königsberg and Friedland. That evening it was learned that the Russians had crossed the Alle at Friedland, which Lannes had already been instructed to occupy next day. The battle of Friedland (*q.v.*), on June 14, ended with the crushing defeat of the Russians, who suffered 25,000 casualties. Meanwhile the corps detached to keep the Prussians away from the battlefield had driven Lestocq into Königsberg, which he abandoned on June 16, withdrawing his forces to join Bennigsen at Tilsit. Napoleon reached the Niemen on June 19 and found the Russians ready for an armistice.

11. The Treaties of Tilsit.—A variety of political motives, as well as his reverses in the field, prompted Alexander to make peace; among them were his dissatisfaction with Great Britain and his belief that a French invasion of Russia would stimulate opposition to his regime. Yet Napoleon had not the means to con-

template an early invasion of Russia and had resolved, should Alexander remain in the war, to maintain his forces on the Niemen and to await the eventual reappearance of the enemy army.

Alexander was ready to accept not only peace, but an alliance with France. He hoped to acquire the greater part of Turkey's Balkan possessions, though Constantinople itself was not to fall to his share. Furthermore, an understanding with France and hostility toward Great Britain would give him the opportunity to pose as an arbiter of European affairs in common with Napoleon and to preserve Russia's Polish lands. Though Napoleon would not agree to restore Prussia's western territories in exchange for the cession of Polish provinces to Saxony and excluded Frederick William from the Franco-Russian negotiations and from the secret alliance signed at Tilsit on July 7, 1807, Russia lost nothing in the peace treaty of the same day.

The settlement between France and Prussia (July 9, 1807) furnished the spoils of the recent campaigns. Prussia was reduced to half its former population, losing all possessions west of the Elbe and almost all the territory gained in the three partitions of Poland. Danzig was to be a free city, garrisoned by the French, and Prussia was to be occupied by French forces till a heavy war indemnity had been paid. Further, Prussia agreed to close its ports to British trade and, if necessary, to join Russia and France in war against Great Britain.

The ceded territory west of the Elbe was distributed mostly between Murat's grand duchy of Berg and the new kingdom of Westphalia (created for Jérôme Bonaparte in Aug. 1807 and including also Brunswick and Hesse-Kassel); but East Frisia went to Holland, and some other lands were left at Napoleon's disposal. The bulk of the Polish provinces, with a population of 2,000,000, were made into the duchy of Warsaw for the king of Saxony, with a French garrison. Westphalia entered the Confederation of the Rhine, into which Mecklenburg and Oldenburg followed in 1808.

VII. THE CONTINENTAL SYSTEM AND THE BLOCKADE, 1807–11

Napoleon's Berlin decree of Nov. 21, 1806, had already declared that the British Isles were under blockade and that "no ship which comes directly from England or the English colonies . . . shall . . . enter any of our harbours." The secret Franco-Russian alliance of Tilsit furthered his scheme for economic warfare against Great Britain, since the co-operation of Russia should permit the complete closure of the Baltic to British shipping and hasten Austrian participation in the continental system. Alexander undertook to support France against the British if they did not consent by Nov. 1, 1807, to acknowledge the complete freedom of the seas and to return the conquests made since 1805: if they refused, France and Russia would "summon the three courts of Copenhagen, Stockholm and Lisbon to close their ports to the British and declare war."

1. The Coercion of Europe.—Soon informed of the Franco-Russian agreement, the British government tried to prevent Denmark from joining Napoleon's continental system. On July 26, 1807, Adm. James Gambier sailed for Copenhagen with a massive fleet, and his junction with W. S. Cathcart's troops, evacuated from Swedish Pomerania, enabled him to land 27,000 men near Copenhagen on Aug. 16: the Danes were offered an alliance and told that in any case they must surrender their fleet for the duration of the war. Rejection of this ultimatum led to the bombardment of Copenhagen (Sept. 2–5), and the Danes capitulated on Sept. 7. The British withdrew with 18 Danish ships of the line and many smaller vessels. Denmark signed an alliance with France on Oct. 30, 1807.

On July 19, 1807, Napoleon informed the Portuguese that they must join the continental system; ten days later he ordered the concentration around Bayonne of 20,000 troops under Junot. The Portuguese tried to placate both belligerents by proposing to refuse to confiscate British goods, but to close their ports and to go through the motions of making war on Great Britain; but neither side would accept such a policy. In mid-October the French troops set out for Portugal, marching through Spain. The Franco-Spanish convention of Fontainebleau (Oct. 27) regulated a partition of Portugal: the northwest, with Oporto, should go to the house of Bourbon-Parma in return for the cession of Etruria to France; Algarve and Alemtejo (Alentejo) were to go to Manuel de Godoy, the Spanish court's favourite; the rest was to be at Napoleon's disposition. On Nov. 30, Junot's vanguard reached Lisbon, whence the Portuguese royal family had embarked for Brazil with a British escort. On the pretext of supporting Junot in Portugal, Napoleon was organizing three more army corps for Spain.

In Italy, Tuscany (Etruria) was annexed to the French empire in pursuance of the convention of Fontainebleau; Parma was also formally incorporated into the empire; and the papal Marches were added to the kingdom of Italy in April 1808, to extend French surveillance of the Adriatic coast. Russia declared war on Great Britain on Oct. 31, 1807, and Prussia followed suit on Dec. 1, apologizing secretly to the British government for its action, as also did Austria, which had joined the continental system in October and was forced to announce a state of hostilities with Great Britain early in 1808.

Russia, having begun to mass forces on the Finnish frontier in Nov. 1807, invaded Swedish Finland, with Danish support, on Feb. 21, 1808. The British granted Sweden a subsidy of £1,200,000, but the nature of King Gustavus IV's plans made it impossible to find a basis for common military action, and the 12,000 troops under Sir John Moore, sent to Göteborg in May 1808, returned without having landed. British shipping, however, continued to supply Swedish markets and to engage in contraband trade with the other Baltic countries.

2. The Orders in Council and Napoleon's Decrees of 1807.—The British further retaliated to the Berlin decree and the Tilsit agreement by the orders in council of Nov. 11, 18 and 25 and of Dec. 18, 1807, which prescribed that any port closed to the British was to be regarded as under blockade and that, under pain of confiscation, any neutral vessel sailing to or from such ports was to put in at a British port to obtain a licence to trade with the enemy and to pay customs duties (now increased to 20%–30%) on its cargo. By taxing neutral, principally American, trade with enemy colonies, the orders favoured the interests of British merchants and planters, who had been complaining of foreign competition. As far as was practicable, the continent of Europe was to receive its commerce through Great Britain; and up to the point where British shipping capacity proved insufficient, the licence system ensured that this trade was carried in British vessels.

Since in practice the Berlin decree did not prevent neutral vessels from bringing British cargoes into French-held ports, Napoleon intensified his measures by the decree of Fontainebleau (Oct. 13, 1807) and the two decrees of Milan (Nov. 23 and Dec. 17). The decrees of Oct. 13 and Nov. 23 classed all colonial produce as British unless carrying a certificate of origin, while that of Dec. 17 declared that "all ships which had submitted to the British [orders in council] were denationalized, and good and lawful prize; and every ship sailing from or to Great Britain or any of its colonies . . . was good and lawful prize."

The effect of the French and British regulations was to leave the neutrals with the prospect of being taken as prizes at sea by the British or in port by the French. On Dec. 22, 1807, the United States imposed an embargo on belligerents adopting measures against neutral shipping, a decision which favoured France and damaged British interests, since the French conducted their trade in neutral ships. The U.S. embargo was unpopular with many sections of U.S. opinion and was not completely effective, despite further legislation in 1808 and the Enforcement act of Jan. 9, 1809; but it contributed to the crisis which overtook Great Britain in 1808.

3. The Spanish Insurrection and Erfurt (1808).—French troops had installed themselves in Burgos, Pamplona and Barcelona by the end of Feb. 1808. Murat left Burgos for Madrid on March 15, but his approach provoked riots in the capital, which led to Godoy's imprisonment and to the enforced abdication of Charles IV in favour of his son, Ferdinand VII, on March 19, four days before Murat's arrival. Charles and Ferdinand were summoned to Bayonne, where on May 10 Napoleon obliged them to resign the kingdom to his brother Joseph. Meanwhile more seri-

ous rioting in Madrid (May 2) was followed by nationalist insurrections throughout Spain. Joseph entered Madrid on July 20 but soon had to retire beyond the Ebro. For an account of the ensuing operations in Spain and Portugal, *see* PENINSULAR WAR.

From the first the war in Spain affected France's relations with the eastern powers. The Franco-Russian entente was disliked in Russian governing circles, and they felt further dissatisfaction at Napoleon's treatment of Prussia and at his proposals for the division of Turkish territories. Napoleon was now anxious to enlist Russian support to guard against Austrian and German moves while the bulk of his forces were engaged in Spain. Having concluded a convention with Prussia whereby the French were to evacuate Prussian territory except certain strong points on the Oder (Sept. 8), Napoleon on Sept. 27, 1808, met Alexander at Erfurt. His concessions failed to impress Alexander, who refused to put any effective pressure on Austria; but at least the treaty of Erfurt (Oct. 12) renewed the Tilsit alliance, and Napoleon could now expect to be free to concentrate on Spain. The Grande Armée was dissolved, two corps alone remaining in Germany under Davout.

When Napoleon, at Vitoria, on Nov. 6, 1808, took over command of the 70,000 French in Spain north of the Ebro, the only solidly constituted force opposing him was that of the 20,000 British under Sir John Moore, reinforced by 13,000 infantry disembarked at La Coruna on Oct. 26; and within a month Napoleon had occupied Madrid. Moore resolved (Dec. 6) to assist the Spanish by moving with 26,000 men against the communications of the still dispersed French forces; but on Dec. 23 he received news of a French concentration against him and next day he began his retreat. Having given up his direction of operations on Jan. 3, Napoleon left Valladolid for Paris a fortnight later, to face the danger from Austria (*see* below). His brief experience of Spanish warfare had shown him some of its difficulties, and he left Spain unsubdued, but he was not prepared to abandon his enterprise.

4. Effects of Economic Warfare.—The opening of Spain, Portugal and South America to British trade helped to offset the drop in Great Britain's exports to Europe. Whereas Great Britain's exports to northern Europe in "real" (as opposed to official) values fell from £16,600,000 in 1805 to £5,400,000 in 1808 and recovered only to £14,500,000 in 1809, sales to America outside the United States for the same years rose from £8,500,000 to £18,100,000 and to £19,800,000. Much of the increase in South American business was financed by credit, and the default of the Spanish colonies was among the causes of the economic crisis of 1811.

A parallel development in shipments to the Mediterranean offset the damage done by Jefferson's measures in North America. While shipments to the United States fell by £6,300,000 between 1805 and 1808, those to the Mediterranean grew fourfold to £6,800,000. The effect of U.S. measures against British commerce was greatly eased in 1809, for while the Non-Intercourse law of March 1809 maintained the prohibitions on trade with belligerents, it did not include the Iberian peninsula and Scandinavia, and U.S. ships were able to make their way to nonneutral ports. British exports to the United States had fallen to £5,300,000 in 1808; for 1809 they were £7,460,000.

The continental blockade, however, was already capable of creating substantial strategic difficulties for Great Britain. Imports of grain from Europe sank from 114,000 tons in 1807 to 14,000 tons in 1808, so that the price of wheat, as little as 66*s.* a quarter in 1807, averaged 94*s.* 5*d.* in 1809 and 103*s.* in 1810. It is in this context that the shortsightedness of Napoleon's determinedly mercantilist policy in selling surplus French and allied corn in 1809 and 1810 is most striking.

The effects of the blockade were keenly felt in France and the continental states as well as in Great Britain. European consumers had food enough but missed amenities such as coffee and sugar; cotton manufacturers soon found themselves cut off from their raw materials as well as from competition; and capital was lacking to create new enterprises to offset the absence of British manufactures. French ports and their merchants were hard hit, and difficulties of transportation arose from the greatly increased use of land routes for continental trade. Between 1806 and 1808, when British exports fell by approximately 13%, those of the French empire declined by 27%—to remain at the same level in 1809, when the volume of British foreign trade rose by more than 33%. French customs receipts, 60,600,000 fr. in 1807, were only 11,600,000 in 1809.

5. The French System of Licences.—To increase revenue and to dispose of surplus agricultural production, Napoleon in April 1809 issued licences as a temporary measure, permitting the export of alcohol and foodstuffs in exchange for wood, flax, iron and quinine, or cash; but the concessions were so limited that the licences taken up during the next 14 months represented only 3% of French exports for 1809.

A decree of July 25, 1810, imposed the licence system on all foreign trade; and one of Aug. 5 laid duties of 40%–50% on colonial goods. The entry of colonial goods was conditional on the export of goods of at least equivalent value. British manufactures, however, could not be brought in. Finally, the decree of Fontainebleau of Oct. 10, 1810, prescribed sentences of ten years' imprisonment and branding for the smuggling of British manufactures and up to four years for the importation of unlicensed colonial goods. All goods illegally imported were subject to confiscation; colonial produce was to be sold by the state and manufactured goods were to be publicly destroyed. These measures precipitated the crisis of 1811 on the continent.

Through the decrees of 1810 the French state, in effect, took over the contraband trade, whose costs were commuted into the new customs tariffs. Licences given under the decree of July 25 were restricted at first to trade in French ships, and the modest trade permitted could hardly offset the overall effects of the continental system. Customs receipts increased to nearly 106,000,000 fr. between Aug. 1810 and Dec. 1811. By Nov. 25, 1811, however, only 494 of the new licences had been issued to cover imports worth 27,000,000 fr. and exports worth 45,000,000; and many "exports" were dummies, later jettisoned, to warrant the landing of imports.

6. The Annexations of 1809–10.—Apart from the cessions imposed upon defeated Austria under the peace of Vienna (*see* below), Napoleon extended the frontiers of the French empire in 1809–10 in order to make his continental system more effective. On May 17, 1809, he annexed what had been left of the papal states; and on July 6 Pius VII, who had excommunicated Napoleon, was taken from Rome as a prisoner. On Jan. 3, 1810, Zeeland was annexed and the Dutch provinces between the Scheldt and the Rhine were occupied, before the outright annexation of Holland on July 9. Finally, in Dec. 1810 Napoleon annexed not only Valais but also all northwestern Germany between the Low Countries and the western Baltic, including Hamburg, Bremen, Lübeck, part of Berg, part of Westphalia, Arenberg, Salm and—least happily of all, because its ruling dynasty was closely connected with Russia—Oldenburg.

7. The Crisis of 1811.—The "real" value of Great Britain's exports and reexports, £51,100,000 in 1805 and £49,700,000 in 1808, reached £62,200,000 in 1810. For that reason the slump of 1811, when they fell to £43,900,000, was the more severely felt. Napoleon's recent measures against British commerce with the continent had contributed to this decline, but the crisis was due rather more to the effects of the war itself in encouraging the overrapid development of non-European trade and the growth of inflation. Moreover, financial instability had been increased by speculation. Thus the difficulties of 1811 were general. Though the British suffered more from the slump in trade than did their economically less-developed neighbours, the crisis overtook both Europe and the new world. Popular discontent in Great Britain was exacerbated by the rise in the cost of bread, caused partly by the poor harvests of 1809 and 1810. Economic opinion urged a return to the gold standard, but this would have depressed the economy still further and curtailed Great Britain's contribution to the war in Europe. By its determination to sustain the war, the British government did much to overcome the crisis: having spent £44,200,000 on war services and borrowed £22,500,000 in 1809, it spent £50,200,000 on the services and raised £23,500,000 in 1811

and increased its borrowings by 50% in 1812.

Both France and Great Britain relaxed their commercial measures against each other in Nov. 1811: the British allowed the export of cotton and quinine and admitted French and allied traders; the French permitted the entry of the colonial goods hitherto forbidden—cotton, sugar, coffee, tea, dyes, etc.—and granted licences for trade.

From Nov. 1810 Napoleon had relaxed the Berlin and Milan decrees in respect of U.S. shipping; and in Feb. 1811 President Madison asked the British government to revoke the orders in council. After much delay the British agreed (April 21, 1812), provided that Napoleon had freed American trade from all restrictions. This was confirmed and, finally, on June 23, 1812, the orders in council were revoked—but too late, since the United States had declared war on June 18 (*see* War of 1812). By this time, however, the British contraband trade with Germany was reviving; and after the complete opening of Swedish and Russian ports and an increase in South American trade, exports of British produce and manufactures reached £41,700,000 in 1812 (as opposed to £32,900,000 in 1811), while the volume of reexports rose by more than 50%.

VIII. AUSTRIA'S WAR OF 1809

To Austria the involvement of the French army in Spain offered an opportunity to restore the rights of the Habsburgs in Germany and Italy and to put an end to the growing fear of new French demands. Moreover, though Austria did not intend to sponsor German nationalism, the possibility of identifying the house of Habsburg and its traditions with the struggle to set central Europe free from French domination engendered a degree of exaltation in preparing for war and a kind of popular enthusiasm hitherto unprecedented. Though the reforms undertaken after 1805 had left the Austrian regime unchanged in fundamentals, while the financial condition had continued to deteriorate, the army had been considerably improved. Provision was made for the raising of reserves for regiments of the line. The Landwehr, established on June 9, 1808, was to furnish about 200,000 men, but their value was restricted to providing limited reinforcements for regular units. The military reformers adopted some measure of skirmishing tactics in 1807 and raised 23,000 light infantrymen in Sept. 1808. At the same time, the cavalry and the artillery were reorganized, so that in 1809 there were 36,000 horsemen and 760 guns in the field. A return was made to the requisition systems in order to supplement the previously cumbrous supply trains; and the corps system was adopted, but only in principle.

The threat of Russian intervention could have deterred Austria from aggression, but though Alexander was pledged to help France if Austria eventually declared war, he yet refused to coerce Austria. While they met with little enthusiasm from Great Britain and got no heavy British subsidy to defray the cost of their mobilization, the Austrians could still count on a substantial effort to distract Napoleon: the British cabinet had agreed on the necessity to intervene in Europe and was considering whether to strengthen the British forces in Portugal, to send an expedition to the Netherlands or to make a diversion in the Baltic.

News of Austrian preparations for war prompted Napoleon to return to Paris from Spain in Jan. 1809. The threat to his regime was greater than any that had emerged since 1805, and his difficulties were reflected in the high proportion of young recruits and foreign troops in the forces that he hurriedly assembled. The conscription class of 1809 had been summoned in Jan. 1808; a further draft of 20,000 had been taken from each of the classes of 1806–09 in September; and 80,000 of the class of 1810 were called up in December. German contingents furnished nearly one-third of the striking force of 174,000 which assembled on the Danube in mid-April 1809. The *garde*, recalled from Spain to stiffen the new army, had still to come up.

For the Austrians, the archduke John was to lead 47,000 against Eugène de Beauharnais in northern Italy; 10,000 were to go to the Tirol and 7,000 to Dalmatia; and 35,000, under the archduke Ferdinand, were to guard Galicia against J. A. Poniatowski's 19,000 Poles and the dangers of a popular rising. The principal effort, however, was to be along the Danube, where the archduke Charles was to have 190,000 men at his disposition. Charles had first planned to move from Bohemia to place his army between the assembling French forces and attack Davout's 60,000 troops around Regensburg on the Danube; but eventually, declining to leave Vienna uncovered, he sent the bulk of his forces via Linz to take the offensive south of the Danube. Though this course involved delay and diminished his advantage, it promised substantial success provided that he struck promptly.

1. Landshut and Eckmühl.—Launching his offensive before the French completed their concentration, Charles entered Bavaria at Braunau, on the Inn, on April 9, 1809. If he had moved quickly he might have surprised the French at Neustadt on the Danube in the middle of their concentration; but he did not reach their outposts on the Isar till April 15. With him, around Landshut, were 126,000 troops, another 49,000 having been sent up the north bank of the Danube from Passau to a position 30 mi. N. of Regensburg. Commanding in Napoleon's absence, Berthier failed to withdraw Davout from Regensburg, with the result that his forces, dangerously far apart, risked an early defeat in detail, since on April 16 Charles's forward troops had only 15 mi. to march to reach the Danube 20 mi. upstream from Regensburg. Farther up the Danube, Berthier had 33,000 troops around Ingolstadt and 16,000 between Neuburg and Donauwörth, while to the south, along the Lech as far as Augsburg, there were 20,000 under Oudinot. Masséna's force of 40,000, scattered over the area Augsburg-Ulm-Landsberg, had not completed its assembly.

Napoleon arrived at Donauwörth early on April 27, 1809, while Lefebvre's three divisions were still falling back from the Isar before Charles's columns. As the Austrians appeared to be heading northward from Landshut to Regensburg and the Danube, Napoleon formed the plan for using Davout to hold their front while Masséna came up on their rear to cut them off from Landshut. Davout left the Regensburg area to march along the right bank of the Danube in front of the enemy early on April 19: with 47,000 men, he ran no great risks unless he were attacked at once and by the mass of the enemy; and in that case there were 46,000 troops around Neustadt to come to his assistance. In the event, Charles's two eastern columns did not encounter the French as they concluded their advance, and the third, left-hand column was easily contained at Teugen by Davout's rear guard as his vanguard joined Lefebvre's forces at Abensberg. On the same day, April 19, Masséna's advance, on the French right, brought him to a point 30 mi. W. of Landshut, where Johann von Hiller was in command of the two remaining Austrian columns. Napoleon, mistaking Hiller's forces for the mass of the Austrian army, then pressed Masséna to reach the Isar and take Landshut, supposing that, if a large proportion of the Austrian forces were caught in the triangle whose apex was the Isar-Danube confluence and whose sides ran down to Regensburg and Landshut, Charles would be forced either to stand and fight or to attempt escape by crossing the Danube at Straubing or Regensburg. Lannes was given command of the centre of the French front, where he was placed to deliver a blow to the flank of the Austrians at Abensberg on April 20, as they were pushed back toward Landshut by Lefebvre and Davout. On April 21, the 40,000 Austrians around Landshut were threatened by forces of 94,000 converging from the north under Lannes and Vandamme and from the west under Masséna. Masséna however entered Landshut too late to take the Austrians in reverse, and Hiller withdrew toward the Inn. The Austrians suffered more than 9,000 casualties around Landshut and in the retreat and lost 30 cannon and much of their transport.

Regensburg capitulated to the Austrians on April 20, 1809. Reinforced by the two corps sent originally to the north of the Danube, Charles next decided to attack Davout and Lefebvre, who found themselves heavily outnumbered; but on April 22, before he could outflank Davout's left, his own left wing was attacked by Davout at Eggmühl. Napoleon's arrival on his rear compelled Charles to retreat, and during the night the Austrians crossed the Danube unpursued.

A week's operations had cost Austria 30,000 casualties and split the archduke's forces into two groups. Though both groups

were able to retire toward Vienna, north of which their reunited army numbered 130,000 by mid-May, the Austrian reverse confirmed Frederick William in his preference for keeping Prussia neutral. He had, however, thought of joining Austria; and several Prussian officers, headed by Ferdinand von Schill, started a patriotic rising of their own on April 28, 1809, in the hope of encouraging him to intervene against the French.

2. Aspern-Essling.—As Charles withdrew northward into Bohemia, Napoleon advanced on Vienna with the intention of achieving a decision before the Austrian forces in Italy and the Tirol could intervene. Thus the main French army followed Hiller toward Linz, leaving Davout and Bernadotte to observe Charles. To the south Lefebvre advanced via Munich to the Salzach and the Tirol. After a fierce engagement at Ebelsberg on the Traun (May 3, 1809) Hiller reached the Danube and the archduke's army. The French entered Vienna on May 12, but found the bridges broken and Charles's army massed on the left bank of the swollen Danube. To come to grips with the Austrians, Napoleon decided to attempt a crossing a little below Vienna, where islands split the river into smaller channels. His advance guard, sent across on the night of May 20–21, was attacked between the villages of Aspern and Essling; and after more French forces had crossed they were repulsed on May 22 with at least 20,000 casualties, the Austrians losing 23,000. This reverse, the battle of Aspern-Essling (*q.v.*), not only compromised Napoleon's immediate military situation, but lessened his standing in the eyes of Europe. The Tirolese, who had risen in favour of the Habsburgs against Bavarian rule in April but had appeared to be quelled by Lefebvre's arrival in Innsbruck on May 19, retook Innsbruck a week after Aspern-Essling and remained in the field for six more months (*see* HOFER, ANDREAS).

3. The Austrian Campaign in Poland.—In April 1809 the Russian emperor Alexander resumed his war with the Turks. For two months he made no move against Austria except to issue a belated declaration of war (May 5), though he maintained a large force on the Galician border; and when he did intervene in Galicia it was with an eye to his own interests, not to Napoleon's. The archduke Ferdinand had crossed the Pilica on April 17 to reach Warsaw on April 23; and Poniatowski retired to the right bank of the Vistula until the Russians should come up. Ferdinand next advanced down the left bank, but could not cross at Plock or at Torun. Meanwhile Poniatowski assumed the offensive up the river, taking Lublin and Sandomierz in mid-May; but the Russians, entering Galicia in early June, failed to co-operate with him. Ferdinand, returning southward, thus made good his escape.

4. The Southern Fronts.—Defeating Eugène de Beauharnais before the Tagliamento on April 16, 1809, the archduke John had driven the French back to the Adige before the news of Landshut and Eckmühl obliged him to retire. With his forces still too widely dispersed, he withdrew before Eugène across Carinthia and Styria into Hungary and arrived at Körmend on the upper Raab river on June 1. Retiring next to Raab (Győr), he was defeated there on June 14; and though he crossed the Danube next day and reached Bratislava on June 23, he rejoined the archduke Charles several hours too late to take part in the battle of Wagram, whereas Eugène had joined Napoleon beforehand. Far to the west, in Styria around Graz, Ignaz Gyulai continued till June 29 to maneuver against Marmont, who had taken the offensive against the Austrians in Croatia and had been at Laibach by June 3.

5. Wagram.—By the beginning of July 1809 Napoleon had assembled approximately 180,000 men and 488 cannon on the isle of Löbau and in its environs on the right bank of the Danube east of Vienna. On the left bank Charles had about 136,000 men and 414 guns. After a number of diversions along the river, the French army began its passage, below Essling, at 9 P.M. on July 4. Charles withdrew to a strong position six miles north of the Danube above Deutsch Wagram and Aderklaa, from which for two days he strongly resisted French attacks. On July 6, however, he was forced to retreat. In this battle of Wagram the Austrians had given a good account of themselves, while the performance of the French reflected the inferiority of their army to the veteran force that Napoleon had wasted since 1805. Charles retired northward to the Thaya (Dyje), with his forces well in hand, and the French proved slow to develop their pursuit. On July 12, after a last engagement at Znaim (Znojmo), Napoleon was willing to grant an armistice. The Austrians who had entered Saxony and put King Frederick Augustus to flight retraced their steps.

6. The Walcheren Expedition of the British.—The British had decided in May 1809 that they would intervene in the Low Countries. On July 28, an expedition of 39,200 men, the largest that had ever been sent to the continent, sailed for the Scheldt estuary, supported by a fleet of 35 ships of the line, 23 frigates and 350 transports. Its incompetent commander, the 2nd earl of Chatham (John Pitt), instead of marching directly on Antwerp, which might have fallen, wasted precious time on Walcheren Island before Flushing, which he occupied on Aug. 16. Half of his force returned to England during the first week of September, by which time almost 11,000 men had contracted fever. The rest remained to garrison Walcheren till they were taken off in December. Of the expedition's 4,044 dead, only 106 had been lost in action.

7. The Peace of Vienna (Schönbrunn).—Late in July 1809 the Russian emperor asked Napoleon for an undertaking that Poland as a whole would not be reestablished: he could countenance the transfer of much of Galicia to the duchy of Warsaw, but not any arrangement prejudicial to Russia's position in Poland. Both he and Napoleon saw how damaging to Franco-Polish relations it would be if Napoleon complied with this request; but in any case Alexander's conduct since the outbreak of war in April had already shown that Tilsit and Erfurt were to be regarded as establishing a truce rather than an alliance between France and Russia. The war party in Austria drew fresh strength from the deterioration of the Franco-Russian entente, so that the peace negotiations, which opened in the middle of August, proceeded slowly. When Napoleon finally offered part of Galicia and an assurance on Poland to Alexander, the latter on Sept. 1 told the Austrians that he was not prepared to support them in continuing the war.

The peace of Vienna, signed at Schönbrunn on Oct. 14, 1809, was a costly settlement of what had been, militarily, Austria's least unsuccessful war against Napoleon. The Innviertel and the province of Salzburg had to be ceded to Bavaria; part of Croatia, Fiume, Istria and Trieste, most of Carinthia and Carniola went to Napoleon; West Galicia (the Polish territory acquired by Austria in 1795, with Cracow and Lublin) passed to the duchy of Warsaw; and in the east the Tarnopol area was assigned to Russia. Francis of Austria thus lost 3,500,000 subjects and all his coastal possessions. Austria had also to pay an indemnity of 85,000,000 fr. and to reduce the army to 150,000 men.

IX. FRANCE AND NORTHERN EUROPE, 1809–12

Gustavus IV of Sweden abdicated in March 1809. His uncle, who succeeded him as Charles XIII, made peace with Russia by the treaty of Fredrikshamn of Sept. 17, ceding Finland. Sweden next made peace with France by the treaty of Paris of Jan. 6, 1810, and joined the continental system (officially at least). When Bernadotte was chosen heir to the Swedish crown (*see* CHARLES XIV John), Napoleon obtained a declaration of war by Sweden against Great Britain (Nov. 17). This had no effect, and Bernadotte soon told Alexander that he would remain independent of French influence and loyal to the treaty of Fredrikshamn.

Franco-Russian relations were exacerbated early in 1810 when Napoleon's betrothal to the Austrian archduchess Marie Louise was announced before Alexander had declared his mother's refusal of Napoleon's overtures for a marriage alliance with the Russian imperial family. If the suggestion had been unwelcome, the denouement was slighting, and the growth of French influence in Vienna increased Alexander's impatience of French tutelage. The difficulties occasioned to Russia by the continental system, together with Napoleon's own example in permitting relaxation of his commercial measures where French interests were involved, prompted Alexander to issue the ukase of Dec. 31, 1810, forbidding some imports by land (whose provenance was the French empire and the satellite states) and doubling the duty on some French merchan-

dise, and to open his ports to neutral shipping and British goods. Before this, Napoleon had taken the unmistakably hostile course of annexing Oldenburg. Thenceforward France and Russia both prepared for war.

Early in 1811 Napoleon had only the 50,000 troops of the duchy of Warsaw and the 45,000 French garrisoned in Germany to protect his eastern frontier. The Russians could soon put 240,000 men in the field, and Alexander concluded that if the Poles would join him, together with the 50,000 Prussians who could, he believed, then also join him without risk, he "could advance to the Oder without striking a blow." This plan was dropped when the Poles refused to change sides despite Alexander's offer to reconstitute Poland; but Napoleon remained on the alert in the spring of 1811, and by Aug. 16 he was discussing the general plan of a Russian campaign to begin in June 1812.

In Dec. 1811 Napoleon secured Austria's informal agreement to furnish 30,000 men for his campaign against Russia; and by a treaty of Feb. 24, 1812, Frederick William of Prussia, to the dismay of Prussian patriots, consented to the occupation of his country by the Grande Armée on its way to Russia and undertook to provide supplies and materials to it (the cost to be set against the balance of the Tilsit indemnity) and also to send and maintain at full strength a contingent of 20,000 men. Both Austria and Prussia, however, informed Alexander that they would make no serious effort in the forthcoming campaign.

Napoleon offended Bernadotte by opposing the latter's plan for the annexation of Norway to Sweden and by occupying Swedish Pomerania (Jan. 1812) in reprisal for Sweden's failure to exclude colonial goods. Bernadotte therefore sought alliance with Russia; and by the agreement of April 5–9, 1812, it was arranged that the Swedes should invade Germany when the French were deeply enough engaged in Russia and that the Russians should later help the Swedes to annex Norway. On May 28 Russia made peace with Turkey.

X. THE RUSSIAN CAMPAIGN, 1812

For the campaign of 1812 Napoleon summoned the largest army that Europe had ever seen. He also made unprecedented efforts to assemble supplies and transport, but these preparations were quite insufficient for an advance with such disproportionate forces far into Russia. He wrongly supposed that the campaign would be ended within 30 days. Late in February the various elements of the Grande Armée set out on the long journeys which were to bring them to the frontier along Niemen in June.

1. The Invasion of Russia.—The main French army began to cross the Niemen into Russia on June 24, 1812. The total invading force then numbered approximately 453,000; but about 612,000 were to enter Russia during the campaign, and little more than 200,000 of them were French. The non-French contingents were destined for employment in secondary tasks; the spearhead of the invasion force was composed of French troops. Napoleon divided his forces into armies, commanding the principal one himself and providing two auxiliary armies to protect the flanks and rear of his striking force. With him on the Niemen were 227,000 men; next on his right Eugène led 80,000; on the right wing at Grodno were Jérôme with 76,000 and, beyond him, K. P. Schwarzenberg's Austrian contingent of nearly 30,000, charged with the observation of the southernmost of the dispersed Russian forces; and on the extreme French left were Macdonald and Yorck with the Prusso-Polish force of 40,000.

Behind the Niemen the Russian commander Barclay de Tolly's army numbered 118,000. Bagration commanded approximately 35,000 and several thousand Cossacks behind the Bug, while A. P. Tormasov, who was observing Schwarzenberg, led about 40,000. In the north P. Kh. Wittgenstein was advancing westward with 25,000 to defend the Dvina. For reserves, the Russians could call on recruits under training and Cossack and militia formations; but as these were not at once available the Russian command decided to retreat before Napoleon's greatly superior forces.

A forced march brought the French to Vilna on June 28, 1812, but by then Barclay had moved toward the fortified camp of Drissa on the Dvina; and Bagration, against whom Jérôme was making a lengthy march from the south in difficult conditions, avoided Davout's attempt to cut his line of retreat by a thrust through Minsk with two divisions and was able to cross the Dnieper (July 25). Barclay meanwhile had abandoned Drissa and withdrawn first to Vitebsk (July 23), then to Smolensk, where Bagration joined him on Aug. 3, bringing their combined forces to 110,000.

Napoleon, whose march from Vilna to Vitebsk had failed to separate the two Russian armies, now turned southeastward, crossing the Dnieper in the night of Aug. 13–14, 1812. On Aug. 14 an engagement at Krasnoe (Krasny) left Barclay in no doubt of his intentions. The French appeared, 180,000 strong, before Smolensk on Aug. 16 and, despite the resistance of Barclay's rear guard, entered the suburbs next day. Early on Aug. 18 the Russians withdrew, having destroyed the bridges and fired the town; and though their rear guard was defeated by Ney and Murat at Valutina on Aug. 19, the mass of their army eluded pursuit. The French lost nearly 15,000 killed and wounded in the actions of Aug. 16–19.

Meanwhile on Aug. 17, 1812, Gouvion-Saint-Cyr replaced Oudinot on Napoleon's left flank and defeated Wittgenstein at Polotsk. A few days later Schwarzenberg won a success at Gorodechno; but though the French extreme left flank in this sector had been able to contain Tormasov, P. V. Chichagov's approach from the south threatened to double the Russian numbers there. Napoleon halted at Smolensk till Aug. 25, summoning Victor's corps to Smolensk to protect his lines of communication and ordering Augereau's from Germany to Vilna.

Prolonged and rapid marching and commissariat problems, not combat, had already taken heavy toll of Napoleon's strength. If the failure of the transport columns to supply the marching troops reduced the effectiveness of the infantry, the cavalry, so essential to his methods of warfare, were particularly vulnerable: forage was lacking for the 300,000 horses, and disease and excessive work increased their death rate.

Fruitful though Barclay's cautious methods had been, he was replaced by the veteran Kutuzov on Aug. 17, 1812. The new commander was determined to fight a major battle before abandoning Moscow. The French arrived before his positions around the village of Borodino on Sept. 5. The next day was spent in concentrating the army, reconnaissance and preparations; and the inconclusive battle of Borodino (*q.v.*) was fought on Sept. 7. The Russians fell back southeastward to the Nara river, and Napoleon entered Moscow with 95,000 men on Sept. 14. That night the city was fired, partly at least by the Russians themselves.

2. The Retreat from Moscow.—The Russians refused to come to terms; and both military and political dangers could be foreseen if the French were to winter in Moscow. After waiting for a month, Napoleon began his retreat, his army now 110,000 strong, on Oct. 19, 1812. His first intention was to retire via Kaluga and thus to make a long detour through more fertile and unexhausted territory before regaining Smolensk, but after the successful combat of Maloyaroslavets (Oct. 24), where he found Kutuzov in his path, he decided to return by the direct route.

At Vyazma, on Nov. 12, 1812, Napoleon's forces had already fallen to 55,000 men. It was not until Nov. 6 that the first snowstorm overtook the army, to be followed by alternate thaws and frosts till early December, when bitter cold set in. Thus the large majority of Napoleon's losses occurred before the first snowfall. On leaving Smolensk, which had been ravaged in August and was now virtually destitute of supplies, the French found Kutuzov threatening their path at Krasnoe. Kutuzov however declined to bring on a general engagement, and in the intermittent fighting that ensued (Nov. 15–17) the main French forces secured their retreat. Ney, trapped with the rear guard on Nov. 18, was able to escape, with heavy losses, only by crossing the unreliable ice on the Dnieper.

The Grande Armée now numbered 8,000 combatants and 40,000 stragglers. Victor's corps, 15,000 men, who had gone northwestward from Smolensk, and Oudinot's, fewer still, rejoined the army west of Orsha; in their rear Wittgenstein had crossed the Dvina. The French approached the Berezina only to learn that the vital bridge at Borisov had been captured by Chichagov, whom Schwarzenberg had failed to pursue on his march from the south. Ou-

dinot's corps took Borisov, but the Russians burned the bridge before they withdrew. During the night of Nov. 25–26, 1812, two bridges were constructed upstream at Studyanka while a feint to the south distracted the Russians' attention. Oudinot's 7,000 men crossed on Nov. 26, the main body of the army next day. On Nov. 28 the rear guard under Victor held off Wittgenstein's attacks along the east bank while Chichagov's assaults on the west bank were contained by the rest of the army. At 9 A.M. on Nov. 29 Victor's men fired the bridges. From Smorgoni the French continued their march, now in extreme cold, to Vilna (Dec. 9) and thence to Kovno, where a few broken thousands crossed the Niemen to find refuge at Königsberg. A further 40,000 men in isolated detachments subsequently made their way to the Vistula. From the north, Macdonald's corps retired with 16,000 men; in the south, Schwarzenberg and J. L. E. Reynier fell back to the Bug with 40,000. The exhausted Russians, their own forces reduced to 40,000, suspended their advance at the Vistula. Their casualties had also been extremely high: fewer than 30% of the troops who began the pursuit at Maloyaroslavets reached Vilna.

When the remnant of his army was 60 mi. E. of Vilna, on Dec. 5, 1812, Napoleon had handed the command over to Murat and had hastened on ahead in order to reach Paris before the news of his disaster. It is estimated that of the 612,000 combatants who entered Russia only 112,000 returned to the frontier: 100,000 are thought to have been killed in action, 200,000 to have died from other causes, 50,000 to have been left sick in hospitals, 50,000 to have deserted and 100,000 to have been taken as prisoners of war. The French themselves lost 70,000 in action and 120,000 wounded, as against the non-French contingents' 30,000 and 60,000. Russian casualties have been set at 200,000 killed, 50,000 dispersed or deserting and 150,000 wounded.

The dissolution of the Grande Armée meant that the French army could no longer absorb new recruits into well-established formations. Nor could it find trained men and horses on a scale to replace the magnificent cavalry arm destroyed in Russia.

XI. THE CAMPAIGN OF 1813

It was not immediately certain that the Russians would carry the war into Germany. Alexander, however, intended to exploit his new opportunities and resolved to continue his advance. Napoleon hoped, mistakenly, that Austria and Prussia would send reinforcements to assist Murat in maintaining a front until he himself returned with a new army.

1. Prussia's Change of Side.—Prussian resistance to Napoleon was precipitated by the initiative of Yorck, commander of the Prussian contingent under Macdonald. Instead of marching as Macdonald's rear guard, Yorck chose to sign his own convention of neutrality with the Russians at Tauroggen on Dec. 30, 1812, which allowed them to occupy the Prussian territory between Königsberg and Memel so that Macdonald had to continue his retreat to Danzig. On the other wing of the French front, Schwarzenberg signed an armistice on Jan. 30, 1813, and withdrew southward with his Austrian troops, exposing Reynier's corps in its retreat to the Oder. The Poles offered no resistance to the Russian advance, which stood at the Niemen on Jan. 13, reached the Vistula on Jan. 18 and gained Warsaw on Feb. 7.

King Frederick William's first reaction to Yorck's convention of Tauroggen was to declare it the act of "an insubordinate soldier." Gaining confidence, however, he decided to join the patriotic advocates of resistance to France and to capture a leading role in the German War of Liberation. Meanwhile, the exiled statesman Karl vom und zum Stein, whom Frederick William had dismissed from the Prussian government in 1808 and who was known as a spokesman of the anti-French movement in Germany, was installed by the Russians as provisional governor in Königsberg, where the estates of East Prussia met to call for the formation of a Landwehr. Frederick William agreed on Feb. 3 to an appeal for volunteers; and within another week he had abolished exemption from military service.

After negotiation and the use of some pressure on Frederick William, Alexander concluded an alliance with him at Kalisz on Feb. 28, 1813, by which he undertook not to make peace until the kingdom of Prussia had been restored to an area and population equivalent to what it had had before Tilsit, though almost all the territory gained in the second and third partitions of Poland was to be renounced. On March 16 Prussia declared war on Napoleon; and on March 19 Alexander and Frederick William issued a proclamation declaring the Confederation of the Rhine to be dissolved and summoning its rulers to change sides or forfeit their states.

Prussian support was essential to Alexander's plans, since the Russian field army numbered only 64,000 at the end of March 1813, whereas Prussia had 61,500 ready for campaign, 28,000 in garrison and 32,000 in Pomerania and in East Prussia and would have the Landwehr available for service in August. The practical results of Prussian enthusiasm for the German national movement in 1813 have been subject to some exaggeration: it furnished 22,000 volunteers between March and May, while the Landwehr contributed more than 120,000 men, to supply half of the Prussian effectives in the autumn campaign.

Eugène, who had replaced Murat in command of the French forces on Jan. 16, 1813, retreated from Poznan on Feb. 12 and paused only briefly on the Oder (Feb. 18–22) before falling back on Berlin. On March 4, he withdrew from Berlin to defend the line of the upper Elbe, exposing Hamburg, which was captured by Russian cavalry on March 18, and abandoning Dresden, the Saxon capital, where Blücher and his Prussians arrived on March 27.

In April 1813 the British offered subsidies to Frederick William on condition that Hanover, which Prussia had undertaken to forgo, was enlarged and that Prussia would agree with Russia not to make peace without Great Britain's consent. Acceding to the Russo-Swedish agreement of 1812, the British not only assigned Norway to Bernadotte (treaty of Stockholm, March 3, 1813), but allotted him Guadeloupe into the bargain and £1,000,000 toward the cost of the contingent of 24,000 with which he landed in Pomerania on May 18.

2. The Austrian Attempt at Mediation.—Austria was the least prepared of the major European powers for immediate hostilities against France. Metternich distrusted Alexander's designs in Poland and in the Turkish states and was reluctant to assist the aggrandisement of Prussia. On the other hand alliance with France would leave Austria to the mercy of the allies if Napoleon were defeated but would not ensure adequate recompense if he won. In April 1813 Metternich asked Napoleon to agree to the return of Illyria, to the partition of the duchy of Warsaw and to the dissolution of the Confederation of the Rhine, informing him that Austria was about to take up armed mediation and would intervene against the side which failed to agree with its proposals. Austria had guaranteed the integrity of the kingdom of Saxony, and on April 26 King Frederick Augustus undertook to join forces with Austria in the event of war. Metternich was also seeking support from Bavaria, whose loyalty to France was uncertain.

3. The New French Army.—Though the Austrian field army was to number 194,000 by Aug. 1813, only one-third of that number was available during the early months of the year. Napoleon's new levies, hastily raised on his return from Russia, lacked training and experience; and though cannon, muskets, munitions and wagons were found, he had few horses, so that there were only 7,000–8,000 cavalrymen fit to campaign by April 1813. In Sept. 1812 a levy of 137,000 men had been made from the class of 1813; and on Jan. 11, 1813, Napoleon called up the class of 1814 in a contingent of 150,000 men and raised a further 100,000 from the classes of 1809–12. Instead of winding up his Spanish affairs, he withdrew 27,000 troops from the peninsula, leaving more than 150,000 in Spain. In Jan. 1813 the incorporation into the active army of 22 regiments of the *premier ban* of the *garde nationale* provided about 85,000 men for the line. In April he mobilized another 90,000 men of the 1814 class and a further 80,000 of the classes of 1807–12 serving with the *garde nationale*. When he left Paris for the front on April 15 the Russian army in Germany numbered 110,000 men, of whom 30,000 were cavalry, and the Prussian 80,000 men; against them, Napoleon had 226,000 troops and 457 guns.

4. Lützen (Gross-Görschen) and Bautzen.—Napoleon had divided his forces into two armies: the army of the Main under his own command; and the army of the Elbe led by Eugène. In the

last days of April 1813 Napoleon reached the Saale with 140,000 men, of whom only 7,500 were cavalry, and 372 guns. Napoleon proposed first to march on Leipzig, outflanking his enemy, then to turn southward to drive the allies against the Erzgebirge mountains. Late on April 30 the army of the Elbe (62,000) was around Merseburg and the army of the Main along the Saale west of Weissenfels, while the allied troops under Wittgenstein (64,000 infantry, 24,000 cavalry and 552 guns) were grouped south of Leipzig, almost at right angles to the French line of operations.

On May 1, 1813, Napoleon entered Lützen; the army of the Elbe had moved from Merseburg to Schladebach and the leading corps of the army of the Main from Weissenfels to Lützen, while the *garde* advanced to Weissenfels and the two rear corps closed up on Naumburg and Stössen. During the next day Ney was to remain at Lützen, to protect both the movement of the army of the Elbe on Leipzig and the approach of the rearward corps of his own army of the Main as they came up to Lützen. Ney disposed his troops rather carelessly and failed to reckon sufficiently with the danger of an allied attack. Wittgenstein was thus prompted to attempt to detach the flank guard under Ney, split the enemy forces and drive the army of the Elbe back upon the Elster river.

On May 2, 1813, the allies opened their cannonade at Gross-Görschen near Kaja, taking Ney's corps by surprise as Napoleon was superintending the attack on Leipzig. Napoleon ordered his troops to concentrate at Kaja instead of continuing their approach to Leipzig (now in French hands) and reestablished his front while waiting for Bertrand to intervene on the allied left flank and for Macdonald to cut the enemy's retreat to the Elster. Both came slowly to the battlefield and the struggle ended at nightfall. Covered by his numerous cavalry, which prevented pursuit, Wittgenstein retired in good order. The French had purchased their inconclusive victory at a cost of about 20,000 killed, wounded and captured; the allies had lost 12,000. However, the retreat of the allies caused Frederick Augustus of Saxony to abandon them, and his army now joined the French.

On May 3, 1813, Ney was instructed to move northeastward on Torgau and Wittenberg while the army of the Elbe followed the allied retreat on Dresden. From Dresden the Russians continued their retreat to the Spree, the Prussians bearing northward before rejoining their allies at Bautzen. In the north 30,000 under F. W. von Bülow were to cover Berlin. On May 8 Napoleon entered Dresden, where he spent over a week in reorganizing his forces and establishing a base of operations against the main allied army and Berlin. Eugène was sent to Italy and the armies of the Main and Elbe were divided between Napoleon and Ney.

On May 18, 1813, Napoleon set out for Bautzen to seek a decisive battle. Having first ordered Ney to send two of his corps toward Berlin, he subsequently countermanded this order and summoned all Ney's forces to Bautzen, but the new instructions arrived too late to ensure the necessary concentration of strength. The allies had assembled 96,000 men on the Spree around Bautzen; and Napoleon was determined to engage them by a preliminary attack on May 20—to be completed when Ney should arrive from the north next day to attack their flank and rear, cutting their lines of communication and pushing them toward the Erzgebirge. On May 20 the preliminary attack was successful; but on May 21 Ney, who reached Preititz with more than 40,000 in hand, allowed himself to be drawn into an inconclusive encounter with the allies' right wing. The restricted extent of Ney's outflanking movement and the heavy superiority of their cavalry allowed the allies to escape once more when they began their retreat eastward at 4 P.M. French casualties were about 20,000 men, the allies' half as many.

Having crossed the Katzbach on May 26, 1813, the allies turned southward with the intention of safeguarding Silesia. On June 1 they reached Schweidnitz (Swidnica) and the French occupied Breslau. In the north, Davout's troops had retaken Hamburg on May 30.

5. The Armistice and the Reichenbach Treaties.—Though the French had paid heavily for their partial victories, Napoleon still enjoyed a numerical advantage, and the allies were materially in poor condition; yet on June 1, 1813, he proposed an armistice which was accepted on June 4 by the Russians at Pläswitz and by the Prussians at Poischwitz and was extended subsequently from June 20 to Aug. 10 for an unrealistic discussion of peace terms at Prague. The Prussian Landwehr and the Austrian army had not yet entered the field, but the French offensive had spent its force. Napoleon had lost 25,000 more men than the allies; his army lacked ammunition and supplies and was exhausted by continual marching (the number of sick had risen to 30,000); and above all he was short of cavalry. He counted on matching the allies' increase in strength during an armistice and on putting sufficient cavalry into the field to secure a decision.

At Reichenbach (modern Pol. Dzierzoniow), in Silesia, British plenipotentiaries signed a treaty with Frederick William on June 14, 1813, and another with Alexander on June 15. It was agreed that Hanover should be restored and enlarged, that Prussia's territories should be made equivalent to those of 1806 and that the three powers should not treat separately with Napoleon. Great Britain was to provide £2,000,000 toward the support of the 240,000 men in the Russian and Prussian field armies. There followed, on June 27, a third treaty of Reichenbach, between Austria, Russia and Prussia, whereby the Austrians undertook to enter the war if Napoleon did not accept their terms. These terms, together with their allies' still more exacting demands, included the disappearance of the duchy of Warsaw, the Confederation of the Rhine and the German annexations and the surrender of Holland, Italy, Spain and Illyria. The news of Wellington's crushing victory at Vitoria, in the Peninsular War, strengthened the allies' morale considerably. By July 5 Castlereagh, the British foreign secretary, was ready to adopt the continental powers' conditions for peace, to demand Sicily for the Bourbons and to seek the allies' acknowledgement of Bernadotte's claims. The armistice ended on Aug. 10. Austria declared war two days later. The treaty of Teplitz (Sept. 9) confirmed the Austro-Russo-Prussian alliance.

6. Dispositions for the Autumn Campaign.—Despite Austria's entry into the war, Napoleon had virtually kept pace with the allies' increase in strength, for he now commanded 442,000 men of whom more than 40,000 were cavalry, excluding the 26,000 men in garrisons on the Elbe, and 1,284 guns. The Russians began the autumn campaign with 184,000, the Prussians, whose Landwehr was becoming available for service, with 162,000; the Austrians contributed 127,000, the Swedes 23,000 and the Anglo-German contingent 9,000: in all more than 500,000 men and 1,380 guns. Napoleon had only 43,000 men in reserve, however, while the allies' reserves and besieging forces numbered 143,000 without counting the 112,000 troops dispersed in fortress duty.

After considerable discussion the allies decided to divide their forces into three armies: the army of Bohemia under Schwarzenberg (accompanied by Alexander and Frederick William), consisting of 127,000 Austrians, together with 82,000 Russians and half as many Prussians; the army of Silesia under Blücher, a Russo-Prussian force of more than 100,000; and the army of the North under Bernadotte, comprising the Swedish contingent, 73,000 Prussians and a Russian detachment, in all 125,000 men. The first army would advance on Dresden up the western bank of the Elbe and the third on Wittenberg, protecting Berlin, while the second would assist either the first or the third as the course of events should demand. It was agreed that the allies should avoid battle with Napoleon and attack his subordinates.

Napoleon's autumn campaign of 1813 was the worst conceived and most disastrous of his career. He was determined to relate his strategy to the fortresses which his forces occupied, thus reducing his scope for movement; and though there were good reasons for his decision to defend the line of the Elbe, it also posed difficulties which he failed to resolve. In the first place, it required the retention of Dresden as his principal base of operations. Yet if he moved the bulk of his forces northward to join Davout from Hamburg and J. B. Girard from Magdeburg in attacking the army of the North, he would loosen his grip on the king of Saxony and allow the army of Bohemia and the army of Silesia to unite before Dresden. As he decided to concentrate against the latter two armies, Oudinot was left exposed in the north to contain Bernadotte's much superior forces. With the deduction of Davout's 40,000 at Hamburg and the garrisons along the Elbe, Napoleon

greatly reduced both his capacity to maneuver and the number of troops immediately available for the field.

7. Dresden.—Napoleon did not know that the allies had decided to increase the army of Bohemia to 250,000 men, and he resumed operations intending to stand on the defensive in the south, with his base at Dresden, till the allies should show their hand, and to seek a decision in the north, where Oudinot (with 70,000) and Davout from Hamburg would converge upon Berlin. At Bautzen, on Aug. 17, 1813, he learned that 40,000 Russians from the army of Silesia were marching to Bohemia. He proposed to deal first with Blücher and then with the armies of Bohemia and of the North. Blücher having advanced toward Löwenberg on the Bober (Lwowek Slaski on the Bobrawa), Napoleon crossed the river on Aug. 21 only to find that Blücher had retreated. Returning to Görlitz, he learned on Aug. 23 that the advance of the army of Bohemia had obliged Gouvion-Saint-Cyr to fall back on Dresden. Leaving Macdonald with 75,000 men to hold Blücher east of the Bober, Napoleon set off westward in haste, at the same time ordering Vandamme to march to Stolpen, where he intended to assemble the remainder of his forces on Aug. 25 so that they could appear en masse at Pirna in Schwarzenberg's rear. He himself arrived at Stolpen on Aug. 25; but so dangerous was the situation at Dresden that he instructed the bulk of his forces to proceed directly on the city while Vandamme continued alone to Pirna. At 10 A.M. on Aug. 26, the *garde* entered Dresden, having marched 90 mi. in 72 hours. Schwarzenberg, who had meant to launch his attack at 4 P.M., now decided to retire, but too late to prevent the beginning of the engagement. Though Napoleon led only 70,000 men against an enemy twice that number, he succeeded in pushing his opponents back before nightfall; he was joined late that night by Marmont and Victor's corps. The battle was resumed at 6 A.M. on Aug. 27, the French driving back Schwarzenberg's right and overwhelming his left. At 4 P.M. the allies withdrew in disorder, though their retreat was not heavily pressed; they had lost 10,000 men killed and wounded, more than 13,000 captured and 26 guns. The French began their pursuit early on Aug. 28, but the less effectively because Napoleon became ill and retired to Dresden. Illness and the shortcomings of his corps commanders deprived him of the full reward of his last major victory.

A succession of reverses soon destroyed the effect of Dresden. On Aug. 23, 1813, Oudinot had been defeated by Bülow at Grossbeeren, with the loss of 3,000 men, and retired behind the Elbe. On the evening of Aug. 28 news reached Dresden of Macdonald's rout by Blücher on the Katzbach (Aug. 26), in which the French had lost nearly 20,000 men and more than 100 guns. Vandamme, pressing on toward Teplitz with 38,000 men to intercept the retreating army of Bohemia, became separated from his colleagues and on Aug. 30 was surrounded at Kulm; he lost about 15,000 men in a rout that destroyed his corps as an organized force.

8. The Allies' Convergence.—Napoleon, still anxious to reach Berlin, replaced Oudinot by Ney, whom he sent to hold Bernadotte away from the Elbe. On Sept. 3, 1813, he left Dresden to rally Macdonald's army, which he led forward to Hochkirch—again to find that Blücher had ordered a retreat to the Neisse. Schwarzenberg, having approached Dresden once more (Sept. 5), retired to Teplitz when Napoleon turned south. Ney crossed the Elbe to be completely defeated at Dennewitz on Sept. 6, where he lost about 22,000 men and 53 cannon. Bernadotte, whose Swedes had been absent from both Grossbeeren and Dennewitz, continued to maneuver along the right bank of the Elbe.

At Pirna, where on Sept. 18 he had finally rejected a plan to attack the army of Bohemia, Napoleon was wrongly informed that Bernadotte had crossed the Elbe at Rosslau. Returning to Dresden on Sept. 21, he reinforced Macdonald on Aug. 22 to push Blücher on to his prepared positions near Bautzen. More false news of Bernadotte's arrival on the Elbe at Wartenburg then caused him to evacuate all areas east of the river save for the bridgeheads in French hands. Blücher now decided to join Bernadotte, who arrived before Wartenburg on Sept. 24, while Schwarzenberg's army, 180,000 strong, left the Dresden area to march on Leipzig, arriving around Chemnitz on Sept. 26. Blücher defeated Bertrand's 14,000 at Wartenburg a week later and completed his crossing of the Elbe next day (Oct. 4), when Bernadotte led 76,000 across at Rosslau, pushing Ney before him. Napoleon resolved to take advantage of the allies' deliberate advance: against them, and operating on interior lines, he disposed of 250,000 men. On Oct. 2 he sent Murat to Freiberg to take command of 45,000 men to resist Schwarzenberg's march on Leipzig. On Oct. 5 he ordered Gouvion to retain Dresden with 40,000 while he attempted to defeat Blücher and Bernadotte with the rest of his forces. Prudently, on Oct. 7 he instructed Gouvion to evacuate Dresden, but he countermanded the order on the same day. Marching 50 mi. in two days, he had assembled 150,000 men around Wurzen, east of Leipzig, on Oct. 8, with whom he proposed to attack Blücher at Düben; but Blücher, covered by the Saale, retreated to join Bernadotte's army near Halle on Oct. 10.

9. Leipzig.—Prevented by the advance of the army of Bohemia from pursuing Bernadotte and Blücher, Napoleon planned to attack it when Schwarzenberg had committed it to an engagement in the Leipzig area. On Oct. 14, 1813, he ordered his troops to Leipzig. Had Napoleon been able to concentrate his forces on that day, Schwarzenberg would have been exposed to defeat on the Elster and Pleisse rivers to the south; but early on Oct. 16 Napoleon was still waiting for Macdonald, and at 9 A.M. Schwarzenberg opened his attack on the heights of Wachau. The battle of Leipzig (*q.v.*), or Battle of the Nations, was begun. When it ended, with the French withdrawal in the early hours of Oct. 19, the allies had lost approximately 55,000 men; French killed and wounded have been estimated at 38,000 men but the total French losses were about 60,000 men, with 325 guns and enormous quantities of matériel.

Napoleon's principal forces crossed the Saale at Weissenfels on Oct. 20, 1813, and halted at Erfurt from Oct. 23 to Oct. 26. Meanwhile Bavaria had concluded an armistice with the allies on Sept. 17 and joined the coalition, by the treaty of Ried, on Oct. 8. At the end of October 30,000 Bavarians under Karl Philipp Wrede blocked Napoleon's path at Hanau; but they met with heavy defeat and lost 9,250 men. Marching via Frankfurt, the French crossed the Rhine at Mainz (Nov. 2–4), their numbers now reduced to 70,000 men and 35,000 stragglers, among whom typhus had appeared; 120,000 more remained beleaguered in the German fortresses. For the second year in succession Napoleon had lost an army.

XII. THE CAMPAIGN OF FRANCE, 1814

At Frankfurt on Nov. 9, 1813, Metternich, with the reluctant approval of Russia and Prussia, offered peace on the basis of France's "natural frontiers," the Rhine, the Alps and the Pyrenees; but he stipulated prompt acceptance, since the allies did not intend to delay operations. When Caulaincourt, Napoleon's new foreign minister, delivered his assent on Dec. 2 the allies had already withdrawn their proposal.

Castlereagh arrived in Basel on Jan. 18, 1814, prepared to offer subsidies to the value of £5,000,000 to the allies; to demand the restoration of Spain and Portugal and compensation for the Bourbons of Naples; and to abandon some of Great Britain's colonial conquests in return for the establishment of a Dutch barrier. He wanted to unite Belgium with Holland so as to block French expansion and was ready to advocate the extension of Prussia's frontiers to the west. His ability and, even more, the strength of his position permitted him to intervene between Alexander and Metternich, so as to bridge divisions growing between Russia and Prussia on the one hand and Austria on the other.

By the end of Dec. 1813 Napoleon had only 60,000 troops to defend the Rhine frontier and a further 30,000 ready for early operations, while the allies were about to invade France with their three armies: that of the North via the Low Countries; that of Silesia, still under Blücher, between Coblenz and Mannheim; and that of Bohemia, still under Schwarzenberg, via Switzerland, the Jura and Langres. In the north, Bernadotte remained to contain Davout at Hamburg, leaving 20,000 men under Bülow in Holland and 50,000 with Ferdinand von Wintzingerode around Wesel. Blücher had 50,000 men at Mainz and Schwarzenberg 180,000 around Basel.

In Italy, Eugène was to conduct a defensive campaign with 50,-

000 against 75,000 Austrians. Soult with 60,000 men strove to halt Wellington's advance with greater forces from Spain. Murat, as king of Naples, had already entered into negotiations with the Austrians and on Jan. 11, 1814, he concluded an alliance by which he was to furnish them with 30,000 men. Bernadotte's arrival in Holstein obliged Frederick VI of Denmark to cede Norway to Sweden on Jan. 14 (in exchange for an indemnity in Germany) and Heligoland to Great Britain. In mid-Nov. 1813 Lebrun evacuated Amsterdam, and rebels at The Hague demanded the return of the house of Orange to the Netherlands.

1. Brienne and La Rothière.—After crossing the Rhine on Dec. 31, 1813, Blücher crossed the Marne at St. Dizier on Jan. 25, 1814. On that date Schwarzenberg's forces stood 150,000 strong between Langres and Bar-sur-Aube, 30 mi. S.W. of Blücher's position. Napoleon meanwhile had assembled the corps of Marmont, Victor and Ney, in all 41,000 men, around Vitry-le-François, 20 mi. N.W. of St. Dizier; 20,000 more were under Mortier, in the neighbourhood of Troyes; and Macdonald and Sébastiani, with 10,000–11,000, were en route from Mézières to Ste. Menehould. Learning that Blücher was approaching the Aube with his forces dispersed, Napoleon advanced rapidly toward 25,000 of Blücher's army around St. Dizier and pursued him to Brienne. Here the French had slightly the better of the piecemeal engagement on Jan. 29, in which both sides lost about 3,000 men, but Napoleon failed to prevent Blücher's junction with Schwarzenberg's right wing.

At La Rothière 85,000 men and 200 guns commanded by Blücher attacked Napoleon's 45,000 men and 128 guns on Feb. 1, 1814. The French held out till nightfall and made their retreat along the snow-covered banks of the Aube; they had lost more than 6,000 men (of whom 2,000 were captured) and 60 guns. The allied casualties were of similar size. Next day the allies agreed at Brienne that they should separate, Blücher marching via Châlons-sur-Marne to Meaux, Schwarzenberg via Troyes toward Bar-sur-Seine and Sens. By Feb. 3 Napoleon had 70,000 men between Troyes and Arcis-sur-Aube, and Macdonald had reached Châlons.

2. Champaubert, Montmirail, Château-Thierry and Vauchamps.—Leaving about 40,000 men to contain Schwarzenberg, Napoleon marched against Blücher's left flank. On Feb. 7, 1814, he was at Nogent-sur-Seine while Macdonald was retreating on Épernay and Blücher advancing toward Paris. Having ordered Marmont to occupy Sézanne, Napoleon himself arrived late on Feb. 9, determined to stake all on a last offensive with his heavily inferior forces of 30,000 men. The day before, Blücher's main column had been extended over 44 mi., while Yorck's corps was more than 12 mi. to the north of his line of advance. At Champaubert on Feb. 10, Marmont and Ney routed one of Blücher's corps, an isolated force of 4,000 Russians, of whom only 1,600 escaped. The French now lay across Blücher's line of march, as Blücher had reached Vertus, east of Champaubert, with the rearmost troops, while his leading corps, under F. G. von der Osten-Sacken, was to the west beyond Montmirail. Leaving Marmont to observe Blücher, Napoleon took 18,000 men and hurried to Montmirail, where he defeated Osten-Sacken's 18,000 Russians on Feb. 11, before Yorck (who had been awaiting Macdonald's appearance along the Château-Thierry road) could join battle to extricate them. The allies lost nearly 4,000, the French half as many.

Pursuing Yorck's force and the remains of Osten-Sacken's to Château-Thierry (Feb. 12, 1814) the French drove them with fresh losses across the Marne, whence Mortier was instructed to press their withdrawal northward. Napoleon left Château-Thierry late on Feb. 13 to overtake the troops already sent back to support Marmont, who was trying to hold Blücher off at Vauchamps. Attacking on Feb. 14 and again that night at Étoges, as Blücher retreated, the French inflicted 6,000 casualties as against their own 600. In the four days between Champaubert and Vauchamps, Blücher's army of 56,000 had been scattered by Napoleon's 30,000 and suffered losses of more than 16,000 against 4,000 French. Blücher, however, rallied his divisions around Châlons, where by Feb. 18, his reinforced army numbered more than 50,000. Napoleon had spent himself and his troops to achieve only a postponement of defeat.

3. Schwarzenberg's Advance and Retreat.—Schwarzenberg meanwhile, finding Troyes evacuated by the French, had remained there resting his army (Feb. 7–10, 1814). He then advanced in two columns, one to the bridge over the Seine at Bray, the other toward Fontainebleau. Leaving Mortier and Marmont on Blücher's front, Napoleon set off with the *garde* on Feb. 15 to attack Schwarzenberg. Having joined Oudinot and Victor at Guignes, he issued orders at 1 A.M. on Feb. 17 for a general advance. On Feb. 18 he defeated a rearguard of 10,000 men on the north bank of the Seine opposite Montereau, capturing a vital crossing-point and 3,400 men. Pursued by the French, Schwarzenberg began to withdraw to Troyes, while Blücher marched to Méry-sur-Seine to reunite on Feb. 21 with the army of Bohemia. Schwarzenberg now abandoned his plans for a joint battle with Napoleon in his alarm at Augereau's advance with 28,000 men from the south against his communications. Yet after detaching troops to meet this threat he still had 90,000, who with Blücher's 50,000 gave the allies 140,000 with whom to oppose Napoleon's 75,000, exclusive of Mortier and Marmont's troops to the north. Declining to join Schwarzenberg in his retreat on Langres, Blücher turned north toward Reims to join Bülow and Wintzingerode. On Feb. 23 Bülow's and three Russian corps were detached from Bernadotte's command and assigned to Blücher, who now became strong enough to campaign on his own—the more easily because Schwarzenberg's movements had carried Napoleon first south and then east of the Seine.

4. The Congress of Châtillon and the Treaty of Chaumont.—On Feb. 5, 1814, the allies had opened the congress of Châtillon(-sur-Seine); and on Feb. 7 they demanded that the French should return to the frontiers of 1792. Napoleon, who after the battle of La Rothière had given Caulaincourt a free hand in his negotiations, soon rejected this demand; but on Feb. 17 negotiations were resumed with Caulaincourt. Napoleon's success at Montmirail had led him to demand the Rhine and the Alps as the frontiers of France; and the Austrians, who had sought an armistice on Feb. 17, sought one again on Feb. 24. By the treaty of Chaumont (March 9), however, thanks largely to Castlereagh's intervention, Great Britain, Russia, Austria and Prussia undertook to continue the war till France accepted the old frontiers and acknowledged the independence of the German states, Holland, Switzerland and Spain; to this end each power would maintain 150,000 men in the field and the British would pay subsidies of £5,000,000. The four powers also agreed on a 20-year defensive alliance to meet any later attempt at expansion by France.

5. The Operations on the Aisne.—At Troyes, which he reoccupied on Feb. 24, 1814, Napoleon learned of Blücher's move toward the Marne and Aisne with 60,000 men, against whom Mortier and Marmont had only 18,000. Leaving 42,000 with Macdonald and Oudinot to observe Schwarzenberg, Napoleon sent Ney, Victor and J. T. Arrighi northward to attack Blücher's rear and, on Feb. 27, went himself to Arcis-sur-Aube, whence by advancing toward Fismes, he threatened to cut off Blücher's retreat across the Aisne. Blücher therefore halted his offensive against Marmont and Mortier at the Ourcq on March 1 and withdrew northeastward to join Bülow and Wintzingerode, who were attacking Soissons. The sudden capitulation of Soissons on March 3 eased Blücher's movement and he continued his march on Laon. Safely behind the Aisne, he regrouped his army, which Bülow and Wintzingerode's reinforcements brought up to 110,000 men. Napoleon moved after him with 35,000 followed by 14,000 with Mortier and Marmont, crossing the Aisne at Berry-au-Bac. A confused and bloody encounter with Blücher's flank guard of 30,000 at Craonne on March 7 ended with Blücher's retreat to Laon, both sides having lost approximately 6,000 men. Dividing his forces into two columns, Napoleon was unsuccessful in his attack from the south on March 9; and that night Marmont's corps was surprised and broken up by the allies' cavalry, with a loss of 2,500 prisoners and 45 cannon (it was rallied only at Berry-au-Bac next day). This reverse would have been more extensive still had Blücher not fallen ill and had the Prussians not halted their pursuit. Withdrawing to Soissons, Napoleon next moved to Reims, where he fought a successful engagement against a Russian corps of 15,000.

6. The Allied Advance on Paris.—Meanwhile, Schwarzen-

berg had pushed Macdonald and Oudinot slowly before him toward Provins. Napoleon now marched from Reims to Méry-sur-Seine to attack his communications. Schwarzenberg withdrew to Troyes on the news of Napoleon's approach, and by March 19, 1814, his forces were between the Seine and the Aube. Napoleon crossed the Aube at Arcis with 16,000 men, and Schwarzenberg, with nearly twice as many, was pushed off the battlefield by nightfall of March 20; casualties were about 2,000 on either side. Next day Schwarzenberg resumed the attack with 100,000, and Napoleon had to retreat.

Not strong enough to stop either allied army, Napoleon resolved to move eastward to rally his garrisons in Lorraine and seek to provoke a general rising in order to throw himself against Schwarzenberg's rear. From St. Dizier his light troops moved along the Marne. Blücher marched southward via Châlons across the French rear to draw closer to Schwarzenberg; and at Sompuis on March 24, 1814, the allies determined to advance directly on Paris by parallel routes. Mortier and Marmont were soundly beaten at La Fère-Champenoise on March 25, losing 2,000 killed and wounded, 4,000 prisoners and 50 cannon. With only 12,000 men left, they could not halt the allies, who crossed the Marne at Meaux to reach Bondy on March 29. The garrison of Paris and the national guard brought Marmont and Mortier's forces to 42,000, and on March 30 they fought honourably before the outskirts of Paris, retiring slowly before the allies' 100,000. That night they concluded the city's capitulation. Napoleon hurried westward, reaching Troyes on March 29 and Fontainebleau next day.

7. The End of the War.—On March 31, 1814, the allies entered Paris, where they invited the inhabitants to decide on their future form of government. In the evening, however, the allied leaders determined not to make peace with Napoleon. The French senate on April 2 and the *corps législatif* on April 3 proclaimed the deposition of Napoleon; and on April 6 the senate called Louis XVIII to the throne, subject to his accepting a constitutional charter. At Fontainebleau, meanwhile, the marshals had refused to follow Napoleon in his demand for a last attempt at resistance with his 60,000 troops and had prevailed on him to abdicate in favour of his son. Then Marmont's decision to take his corps into the allied lines (night of April 4–5) uncovered Fontainebleau, and Napoleon agreed to abdicate both in his own name and in his son's. The treaty of Fontainebleau, which he accepted from the allies on April 13, assigned to him the sovereignty of Elba, the title of emperor and an annual stipend. On April 20, he bade farewell to his troops and set out for Elba.

Wellington's forces had already driven Soult from Spain into the south of France; and during February and March 1814 the French continued to retreat eastward from the Adour. At Toulouse on April 10, when the news of the cessation of hostilities had not yet reached the two commanders, Soult was again defeated. In Italy, Murat, having gone over to the Austrian side, had advanced from Naples to occupy Rome, Ancona and Bologna, obliging Eugène to retire from the Adige to the Mincio. In February he opened negotiations with Eugène, which continued intermittently until news was received of the allies' advance on Paris. Hostilities were ended a few days later by a convention (April 16) under which Eugène was to withdraw his forces from Italy.

The allies made peace with Louis XVIII's government by the treaty of Paris (May 30, 1814). They demanded no indemnity and even permitted the retention of nearly all the works of art that the French had taken as spoils of war, but the frontiers of 1792 were restored, except that Montbéliard and western Savoy were left to France (as well as Avignon and the Comtat-Venaissin, annexed in 1791). Overseas, France renounced Tobago, St. Lucia, Mauritius and Seychelles to Great Britain and San Domingo to Spain but regained the other colonies. Finally, France accepted in advance the allies' division of previous French conquests at the forthcoming congress of Vienna (*q.v.*). After the Hundred Days and the final defeat of Napoleon (*see* WATERLOO CAMPAIGN) the second treaty of Paris, signed on Nov. 20, 1815, was more stringent to France.

NAPOLEONITE, or CORSITE, a gabbro showing orbicular, or spherical, structure from Santa Lucia di Tallano, Corsica. The rock when cut and polished makes a beautiful ornamental stone, examples of which are to be found in most petrographical museums. Although often referred to as a diorite, napoleonite in its mineral and chemical composition corresponds to a hornblende gabbro (*q.v.*). The spheroids or orbicules in napoleonite, remarkable for their uniformity in structure, range from ½ in. to 2 in. in diameter and are set in a matrix of variable grain size built up of green hornblende and cummingtonite (*see* AMPHIBOLE) and bytownite feldspar (*see* FELDSPAR: *The Plagioclases*).

The core of these structures consists of material mineralogically similar to the matrix but richer in feldspar; it is followed by a series of broad and narrow zones, respectively, of radiate plagioclase and green hornblende-cummingtonite intergrowths also radially arranged. Both the plagioclase of the core and of the broad zones is distinctly more calcic than that of the matrix. These relations are in accord with the concept that the orbicules developed in a crystallizing liquid and the structure itself has probably arisen by rhythmic crystallization.

Orbicular or spheroidal structures, though by no means common, have been found in the crystalline rocks of Sweden, Finland, the U.S.S.R. and North America. They have been closely studied by the petrologists of Finland and are there known as esboites. The mutual relations in composition and structure of orbicule and matrix in some of these rocks, especially those of Finland, have led to the opinion that the structures are metamorphic in origin, the orbicules developing in a solid or quasi-solid matrix which has in part been converted into a migmatite by metasomatic replacement.

See P. Eskola, "On the Esboitic Crystallization of Orbicular Rocks," *J. Geol.*, vol. xlvi, pp. 448–485 (1938). (C. E. T.)

NAPO-PASTAZA, former province in the Oriente region of Ecuador, east of the Andes mountains. With an area of 33,237 sq.mi., Napo-Pastaza was the largest province in Ecuador. However, it had a population in 1950 of only 25,425. The capital was Tena. In Jan. 1960 the province was divided into the two provinces of Napo (pop. [1962] 24,487) and Pastaza (13,840). *See* EL ORIENTE.

NAPO RIVER, a tributary of the Amazon river in South America. The Napo rises among the volcanoes of the Andes mountains in northern Ecuador and flows southeast to join the Amazon near Iquitos, a town in northeast Peru. Total length is 700 mi. *See* AMAZON.

NAPRAPATHY, a system of manipulative drugless treatment based on a theory that the cause of disease is connective tissue that has become shrunken as a result of injury. A shrunken

strand of connective tissue is called a ligatight and may occur in the spine, thorax, pelvis or elsewhere. It is claimed that such tissue can be corrected by naprapathic treatment, which aims at stretching the shrunken strands. Study of a set of charts showing types of ligatights and manipulations to correct them are held to be an important part of the practitioner's training. Naprapathy was founded in 1907 by Oakley Smith.

NARA, a *ken* (prefecture) in central Kii peninsula (western Honshū), Japan, east of Ōsaka. The total area of the prefecture is 1,426 sq.mi. Its southern and northeastern portions are mountainous, while its northwestern quarter is occupied by the Nara (Yamato) basin, the key lowland. The basin has most of the prefecture's population (825,941 in 1965), main cities, agricultural land and transportation facilities. It is separated from eastern Ōsaka by the Ikoma and Kongō mountains. The Nara basin is one of Japan's most densely settled and historic regions and has many famous temples, buildings and other remains from the past. However, it is being pulled increasingly into the commercial orbit of Ōsaka (less than one hour by electric train), to which it sends a daily stream of commuters, products of its intensive agriculture and a variety of simple cotton goods and handicrafts.

NARA, the capital and largest city of Nara prefecture, is 25 mi. from Ōsaka, in the hilly northeastern edge of the Nara basin. Pop. (1960) 134,577. During 75 years (710–784) it was Japan's capital

WERNER BISCHOF—MAGNUM

SCHOOLCHILDREN IN FRONT OF THE ENTRANCE TO THE TEMPLE OF KATSURA, NARA

and many of the striking artistic accomplishments (Buddhist temples, monasteries, sculpture) of that age are still preserved, grouped around the edge of the celebrated deer park. (*See* also JAPANESE SCULPTURE: *Nara [Tempyo] Period.*) Many artifacts have been preserved for 1,200 years in a log storehouse, the Shōsōin. These splendid remnants of early Japanese civilization attract more than 4,000,000 visitors annually. Besides tourism and administration, Nara is a leading commercial and educational centre and has some manufacturing. (J. D. EE.)

NARA (officially EASTERN NARA), an important water channel in Sind, West Pakistan, now utilized for the Eastern Nara canal (226 mi.), the largest of the Sukkur barrage canals. The upper part of the Nara river was a small channel through which spill water from the Indus, above Rohri, found its way to central and lower Sind. Skirting the sandhills throughout the Thar Parkar desert it discharged itself into the Puran, an old channel of the Indus, which 80 mi. farther south enters the Rann of Cutch. To ensure regular water supply it was connected in 1958–59 with the Indus at Rohri by the 12-mi.-long Nara supply channel. The Eastern Nara is also considered by some as the channel by which the Ghaggar or Hakra (now dry) flowed into the sea. Others believe it to be the old bed of the Indus or the Sutlej. (K. S. AD.)

NARAI (NARAIN), king of Siam from 1657 to 1688, is best known for his conduct of foreign relations. In 1664 he signed a treaty with the Dutch giving them commercial privileges in Siam, including extraterritoriality. He was unsuccessful in establishing a favourable basis for trade and goodwill with the British, and a series of incidents led to a declaration of war against the British East India company in 1687. He welcomed the first French Catholic missionaries to his shores in 1662, because he discovered they could build forts as well as churches. Through the good offices of the missionaries he exchanged political missions with popes and kings. He also engaged in useless, intermittent wars against traditional enemies in Burma, Cambodia and Chiangmai.

Narai's policies caused violent reactions on the part of the court and the people. The whole realm was filled with European-built forts garrisoned by European soldiers. The most powerful minister in the government was a romantic Greek trader, Constant Phaulkon. The missionaries overreached themselves in trying to convert the king to Catholicism and to spread their religion throughout the kingdom. When the king died, foreigners were dispossessed of power or driven out, and Siam remained in comparative seclusion from the west for more than a century thereafter. (C. A. B.)

NARAYAN, JAYAPRAKASH (1902–), Indian political leader and political theorist, was born on Oct. 11, 1902, in the Saran district of Bihar. He was educated locally and at universities in the United States, where he maintained himself by his own exertions and became a Marxist. He returned to India in 1929 and joined the Congress party. He was sentenced to a year's imprisonment in 1932 for participation in the civil disobedience movement. After his release he took a leading part in the formation of the Congress Socialist party, a left-wing group within the Congress party itself. He was imprisoned again in 1939, for opposition to the war effort, but subsequently made a dramatic escape and for a short time tried to organize violent resistance to the government before his recapture in 1943. After his release in 1946 he tried to persuade the Congress leaders to adopt a more militant policy and argued that political independence would be incomplete without a social revolution. In 1948 he left the Congress party, in company with most of the Socialists, and formed a separate Socialist party, which in 1952 merged with another left-wing group to become the Praja Socialist party. But he was becoming dissatisfied with party politics and in 1954 announced that he would devote his life exclusively to the *Bhoodan Yajna* (land-gift) movement (*see* BHAVE, VINOBA). His continuing interest in political problems, however, was revealed in 1959 when he argued for a "reconstruction of Indian polity" by means of a four-tier hierarchy of village, district, state and union councils resembling the "basic democracies" established in Pakistan by Pres. Ayub Khan, which he specifically praised. In April 1960 he organized an Afro-Asian convention in Delhi to protest against Chinese policy in Tibet as well as against the remains of colonialism elsewhere. (KE. A. B.)

NARAYANGANJ, a town in the Dacca district of East Pakistan, stands 8 mi. S.E. of Dacca on both banks of the Lakhya at its confluence with the Dhaleswari, just before the latter joins the Meghna. It has thus steamer connections with all the important inland ports as well as with Chittagong. Pop. (1961) 162,054 including 36,262 in the cantonment. Its good location as a riverport has made Narayanganj a collecting centre of hides and skins and a terminal market for jute. Together with Dacca (*q.v.*) it forms the greatest industrial region of East Pakistan, with the largest number of jute presses and jute and cotton mills. It also has manufacture of leather and footwear and glassworks. The making of underwear is a notable cottage industry.

The town is compact, built on raised low-lying land, with many spacious streets. Old buildings include Kadam Rasul (1801), a shrine built by Ghulam Mohammed of Tippera; two forts built by Isa Khan, one of the Bara Bhaiyas (12 landlords of Bengal), dur-

ing the reign of Akbar; and the Laxmi Narayan building, a Vishnu construction of the 12th century, after which the town is named. Modern buildings include the Dacca-Narayanganj chamber of commerce and industry, National and Grindlays bank, Co-operative house and Seth Tolaram college. There is also a municipal public library. The town has facilities for ship repairs.

(K. S. AD.)

NARBONNE, a city of France, ancient capital of Gallia Narbonensis and now capital of an *arrondissement* in the *département* of Aude, lying on a vine-growing plain 8 mi. (13 km.) from the Mediterranean, 34 mi. (55 km.) E. of Carcassonne. Pop. (1962) 30,388. The town has excellent rail services and is on two main roads. It has a subprefecture and courts of first instance and of commerce.

Surrounded by wide outer boulevards, Narbonne is divided into *bourg* and *cité* by the Robine canal, a branch of the Canal du Midi. Its old buildings include the basilica of St. Paul Serge (11th–14th centuries), a curious and early specimen of the Gothic style in the south, with a churchyard of the 4th century; the unfinished cathedral of St. Just (13th–14th centuries), which consists only of a choir (135 ft. high) flanked by two 234-ft. towers; the church of St. Sebastian, flamboyant Gothic (15th century); and the pure Renaissance-style House of the Three Wet-Nurses (16th century), so named because of the proportions of the three caryatids that support its cornice. Special notice must be taken of the Archbishops' palace, a collection of civil, military and religious buildings ranging from the high middle ages to the 18th century. A part of the palace is used as a town hall, but it shelters also two exceptional museums: the museum of Narbonne prehistory and antiquities and the museum of art and history, with important collections of paintings and ceramics. In the Lamourguier church is one of the world's greatest lapidary museums. Modern buildings include the technical college, and, in a park, the Palace of Arts, Sports and Work, enclosing an Olympic swimming pool, theatre, gymnasium and meeting rooms for workers.

Narbonne has a good trade in wines, salt and tartar. Its honey is renowned. The main industries are uranium and sulfur refining, alcohol distilling, oil milling and the making of wine casks and bricks and tiles.

Narbonne was the capital of the Volcae Tectosages. There the Romans in 118 B.C. founded their first colony in Gaul, Narbo Martius; they built great works to protect the city from inundation and to improve its port. The capital of Gallia Narbonensis, the seat of a proconsul and a station for the Roman fleet, Narbo Martius became the rival of Massilia (Marseilles); but the division of Gallia Narbonensis into two provinces reduced its importance. Alans, Suebi and Vandals each held the city until in 413 it was occupied by the Visigoths, whose capital it afterward became. In 719, after a siege of two years, it was captured and extended by the Saracens. Charlemagne made the city the capital of the duchy of Gothia, and divided it into three lordships—one for the bishop, another for a Frankish lord and a third for the Jews. In the 13th century the archbishopric was seized by the pope's legate, Arnaud Amaury, who took the title of viscount of Narbonne. Simon de Montfort, however, deprived him of this dignity, receiving from Philip Augustus the duchy of Narbonne along with the county of Toulouse. By his expulsion of the Jews Philip the Fair hastened the decay of the city; and about the same period the Aude, which had been diverted by the Romans to flow toward Narbonne, burst its banks, returned to its original bed, and the harbour was silted up. United to the French crown in 1507, Narbonne was enclosed by a new line of walls under Francis I; the last portions of its ramparts were demolished in 1870. The archbishopric was founded about the middle of the 3rd century, its first holder being Sergius Paulus; it was suppressed in 1790.

(HE. J.)

NARCISSUS (d. A.D. 54) was a freedman, who as *ab epistulis* to the Roman emperor Claudius I was responsible for bringing to his attention letters on every kind of subject from cities and officials throughout the empire, and doubtless for drafting replies. This household secretarial post had existed before but had had no political importance; by his influence over the malleable emperor, Narcissus raised himself to be one of the first ministers of state and also one of the richest men Rome had ever known. He was for a long time in league with Messallina (*q.v.*), but fear made him and other freedmen secretaries combine to secure her death (48). Claudius could not remain unmarried, but Narcissus backed the wrong candidate, Claudius' divorced wife Aelia Paetina; hence, on Claudius' marriage to Agrippina the younger, he lost influence to the financial secretary Pallas, who had supported her. His loyalty to Messallina's son Britannicus ensured his death on Nero's accession. It is often held that Narcissus' importance betokens the development of a centralized bureaucracy under Claudius, but the ancient evidence only represents him as a powerful favourite; it is so distorted by social prejudice that his talents and achievements cannot now be assessed.

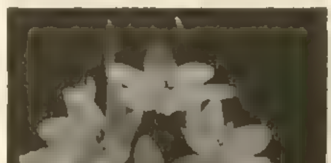
See M. P. Charlesworth in *Cambridge Ancient History,* vol. x, ch. 20, with bibliography (1934). (P. A. BR.)

NARCISSUS, in Greek mythology, son of the river-god Cephissus and the nymph Leiriope, distinguished for his beauty. The seer Tiresias told his mother that he would have a long life, provided he never looked upon his own features. His rejection of the love of the nymph Echo (*q.v.*) or of his lover Ameinias drew upon him the vengeance of the gods. Having fallen in love with his own reflection in the waters of a spring, he pined away (or killed himself), and the flower that bears his name sprang up where he died. According to Pausanias, Narcissus, to console himself for the death of a favourite twin sister, his exact counterpart, sat gazing into the spring to recall her features by his own.

It is a very plausible suggestion of Sir James Frazer in *The Golden Bough* that this story is to be connected with the widespread belief that it is unlucky, or even fatal, to see one's own reflection. This superstition existed in Greece.

Hence is derived the term narcissism, used in psychiatry, and especially psychoanalysis, for a morbid condition in which the subject is intensely interested in his own body.

NARCISSUS, a genus of bulbous plants belonging to the amaryllis family (Amaryllidaceae), native of central Europe and the Mediterranean region; one species, *N. tazetta,* extends through Asia to Japan. From some of these, by cultivation and hybridization, have arisen the numerous modern varieties used in gardens and as cut flowers. The plants have long narrow leaves springing from the bulb and a central scape bearing one or more generally large, white or yellow, drooping or inclined flowers. The flowers are regular; the perianth (calyx and corolla) springing from above the ovary is tubular below, with spreading segments and a central corona or cup; the six stamens are inserted within the tube. The most interesting feature botanically is the corona, which springs from the base of the flower segments and gives the special character to the flower. One classification of narcissuses includes 11 groups or divisions; of these the following five are of chief interest to the gardener:



J. HORACE MCFARLAND CO.

PAPER-WHITE NARCISSUS (NARCISSUS TAZETTA ALBA), ONE OF THE POLYANTHUS NARCISSUSES

1. The hoop petticoat narcissuses are from 4 to 12 in. in height and have grassy foliage and yellow or white flowers. These have the corona in the centre of the flower—very large in proportion to the other parts and much expanded, like a hoop petticoat. They are all regarded as varieties or forms of the common hoop petticoat, *N. bulbocodium*, which has comparatively large bright-yellow flowers.

2. A second group is that of the pseudo narcissuses, of which the common or wild daffodil, *N. pseudo-narcissus,* is the type. This species is found in woods and thickets in most parts of the

north of Europe and is naturalized in the U.S. Its leaves are about 1 ft. in length and 1 in. in breadth and have a blunt central ridge and flat edges. The stem, which is 8 to 18 in. long, bears a single flower. The flowers are large, yellow, scented and slightly drooping, with a corolla deeply cleft into six lobes, and a bell-shaped corona that is crisped at the margin; they appear in early spring. In this species the corona is also very large and prominent. (*See* DAFFODIL.)

3. Another group, with coronas of medium size, includes the fine and numerous varieties of *N. incomparabilis*, one of which has large, double flowers. *N. odorus*, known as the campernelle jonquil, has two to four uniform bright-yellow flowers and is considered a hybrid between *N. jonquilla* and *N. pseudo-narcissus*, although it is found wild in France and Spain.

4. The polyanthus or bunch narcissuses form another well-marked group, whose peculiarity of producing many flowers on the stem is indicated by the name. In these the corona is small and shallow as compared with the perianth. *N. tazetta* is the type of this group. They are general favourites among spring flowers. The Chinese sacred lily, or joss flower, and the paper-white narcissus, forced on a large scale by florists, are varieties of *N. tazetta*. The jonquil, *N. jonquilla*, with yellow flowers, a native of south Europe and Algeria, does well outside in a warm border but may also be grown in pots for early flowering.

5. In the poet's or pheasant's-eye narcissuses (*N. poeticus*) the perianth is large, spreading and conspicuous and the corona very small and shallow. These pheasant's-eye narcissuses, of which there are several well-marked varieties, blossom in succession from early spring to midspring, and all do well in the open borders as permanent hardy bulbs.

Narcissuses are best displayed in naturalized plantings but are also effective in more formal arrangements. Bulbs, available in early fall, should be planted as soon as they are received, so that they may root before cold weather arrives. They should be covered by soil as deep as one and one-half times their height. Narcissuses will thrive in a loamy soil enriched with rotted manure or bone meal, which should not touch the bulbs. After the plants flower, the leaves should be allowed to wither naturally; the bulbs depend upon the foliage for the manufacture of food materials necessary for the resumption of growth next season. *See* also FLOWER: *Commercial Flower Growing.*

Bowles, *Handbook of Narcissus* (1934); Royal Horticultural Society, *Dictionary of Gardening*, vol. iii (1951); the *American Daffodil Yearbook* (1947 *et seq.*); Norman Taylor (ed.), *Taylor's Encyclopedia of Gardening*, 4th ed. (1961).

NARCOTICS, a general term for substances that produce lethargy or stupor and the relief of pain. In a restricted sense, the term applies to opium (*q.v.*) or coca leaves or any compound, manufacture, salt or preparation thereof, even though their action is not narcotic. Prescriptions for these substances in most countries require that the prescribing physician be registered with the proper governmental agency (department of the treasury in the United States) and comply with the regulations furnished by that agency. *See* DRUG ADDICTION; NARCOTICS, LAWS RELATING TO.

(F. L. A.)

NARCOTICS, LAWS RELATING TO. Addiction to narcotic drugs began to be recognized as a social evil in the 19th century, and governments have sought to deal with it along three main lines: (1) control of sources of supply through international co-operation; (2) prohibition by criminal penalties; and (3) treatment of addicts by medical and public health authorities. The United States has been the foremost exponent of international controls, the United States and Nationalist China (Formosa) are prominent for the severity of their repressive laws, and the United Kingdom, followed by the Scandinavian countries, probably has had most success in the medical treatment of addicts. In nearly all countries, however, an attempt is made to balance the need for repressive legislation, on the one hand, and the medical treatment of addicts on the other; the balance varies according to local circumstances. England, for example, unlike the United States, has only a small number of drug addicts and no organized illicit traffic in narcotics; such differences should be kept in mind in appraising the legislation of the two countries.

International Controls.—The opium traffic in the far east was exploited by westerners in the 18th and 19th centuries. The Opium wars (1839–42, 1856–60) were fought to crush Chinese resistance to this exploitation. The United States, however, began to bar its nationals from the traffic by bilateral agreements as early as 1833, outlawed U.S. participation in the China traffic in 1881, and suppressed domestic manufacture of smoking opium by progressively higher taxation after 1890 and by outright prohibition in 1909. In 1909 Pres. Theodore Roosevelt convened a commission of 13 nations, which met in Shanghai to discuss the international problem, and these deliberations led to the Hague Opium convention of 1912.

The Hague convention required each adhering Power to control its production, importation and exportation of raw opium and coca leaves, as well as to regulate its own domestic manufacture, distribution and use, to confine the latter to legitimate medical purposes. Following World War I these objectives were pursued by the League of Nations (ratification of the 1919–20 peace treaties included automatic ratification of the 1912 convention), and there have been many international agreements since: the Geneva convention of 1925, attempting to set up a production quota system and creating a permanent central opium board to administer it; the Geneva agreement of 1925, proposing to bind the principal Asiatic producers of opium to establish government monopolies for easier control; the Geneva convention of 1931, extending the limitations on manufacture and distribution of drugs, and creating an international drug supervisory body to police them; the Bangkok agreement of 1931, calling for government monopolies of the retail sale of opium in Asiatic countries; the 1936 convention (with less than a score of adherents), calling for direct criminal sanctions to punish international trafficking; the protocol of 1946, bringing all prior agreements under the supervision of the United Nations and replacing the Opium Advisory committee of the League of Nations by the UN Commission on Narcotic Drugs; the protocol of 1948, providing machinery for the addition of new drugs to the controlled categories by action of the World Health organization; the protocol of 1953 (with more than 50 adherents), agreeing to drastic limitations on the cultivation of poppies; and the Single convention of 1961, codifying and extending the provisions of the numerous multilateral treaties.

Despite this array of international commitments, the contracting Powers have not co-operated effectively enough to stamp out production for addict consumption nor to curb illicit trafficking. Producing countries in the middle and far east continue to tolerate, if not encourage, lucrative drug industries within their borders; and consuming countries like the United States (which has no domestic production) continue to receive vast supplies via the smuggler and clandestine peddler. (*See* also OPIUM: *Opium Traffic.*)

United States.—By the start of the 20th century narcotic drugs were widely used in the United States. Eating opium and laudanum were sold everywhere. Respectable people suffered from the "opium sickness." Even children's medicines contained opiates, and the medical profession prescribed addicting drugs with little restraint. When heroin was introduced, in 1898, it was widely hailed as a nonaddicting substitute for morphine. In the early 1900s a number of states passed prescription laws. To aid in the enforcement of these laws and to provide the regulation required by the 1912 Hague convention, congress in 1914 passed the Harrison Narcotics act.

The Harrison act, still the basic U.S. drug statute, began as a simple tax measure. It imposed a stamp tax of 1¢ per ounce on opium and coca products and required all who handled them—importer, manufacturer, wholesaler, pharmacist and prescribing physician—to register, to keep records and to make use of special order and purchase forms. But the act also contained an ambiguous limitation: the physician was exempted from its requirements only in prescribing drugs "to a patient" and "in the course of his professional practice only."

Enforcement fell to the treasury department, which was also

charged, in 1919, with enforcement of the National Prohibition act; the department's new prohibition unit thereupon launched twin campaigns against drug users and alcohol drinkers. From the outset, though the Harrison act called merely for collection of the tax, registration was refused to sellers outside the medical profession, and even doctors and pharmacists who ministered to addicts were arrested and prosecuted. Public health facilities (narcotic drug clinics), established in many communities during the period 1918–23 to provide treatment for addicts, were closed. In a series of test cases, culminating in *U.S.* v. *Behrman* (1923), the U.S. supreme court interpreted the ambiguous exemption referred to above to mean that no doctor could lawfully prescribe or administer *any* narcotic drug to an addict, even in a good-faith attempt to cure the addiction or alleviate the symptoms of withdrawal. Though this decision was reversed in *U.S.* v. *Lindner* (1925), treasury enforcement policies have continued to rely on the *Behrman* interpretation.

Estimates of the number of persons addicted to narcotic drugs in the United States at the close of World War I range from 200,000 to 1,000,000 (the latter being the treasury department's official figure). It is certain that a great number, finding themselves cut off from all legitimate suppliers and medical assistance, simply cured themselves. But many turned to the underworld, to a hitherto unknown figure, the "dope peddler"; in doing so they became criminals themselves, creating the richest illicit drug market in the world and the most costly law enforcement problem of our times. In the heyday of bootlegging, there were twice as many federal convictions for drug offenses as for liquor law violations (in 1928, for instance, a federal prison census showed 2,529 prisoners out of a total of 7,138 to be Harrison act offenders); in the mid-1960s, with the addict population of the country estimated to be about 60,000, drug-law arrests by federal and local authorities remained above 20,000 per year. Over 15% of federal prisoners were serving time for drug-law offenses.

The Harrison act was amended by the Marihuana Tax act (1937), placing marihuana in the controlled category, and by the Boggs act (1951) and the Narcotic Control act of 1956. These acts greatly increased the penalties for drug-law violations, introducing mandatory minimum sentences and depriving offenders of the privileges of probation and parole afforded other federal prisoners. A person convicted of any drug-law offense must be imprisoned for at least 2 years (and up to 5, though the court may suspend the sentence for first offenders); on the second offense, the sentence must be 5 to 10 years, and for subsequent convictions the minimum is 10 years and the maximum 40. For offenses in the sale, transfer and smuggling categories, the prescribed sentence for a first offense (without suspension) is 5 to 10 years, and for subsequent convictions, 10 to 40 years. A discretionary fine, up to $20,000, may be imposed with any of the foregoing sentences. Heroin, estimated to constitute 90% of the illicit traffic, was directly outlawed by the 1956 act, and its sale by an adult to a minor was made punishable by life imprisonment or, if the jury so recommended, by death. A number of states have followed the federal pattern of penalties in their own drug statutes.

The United States thus is notable (along with Formosa, where most offenses involving drugs are punishable by summary execution) for the severity of its narcotic laws. But it should also be noted that two of the finest narcotic drug hospitals and research centres in the world are operated by the U.S. public health service, one at Lexington, Ky., opened in 1935 and one at Fort Worth, Tex., opened in 1938.

Great Britain.—Great Britain, also an adherent to the Hague convention of 1912, enacted its Dangerous Drugs act, with regulatory provisions strikingly similar to those contained in the Harrison act, in 1920. The first home office regulations contained a similar ambiguous exemption for the physician: he could possess and supply drugs only "so far as may be necessary for the practise or exercise of his said profession, function or employment, and in his capacity as a member of his said class." But in Great Britain the ambiguity was resolved by a medical commission. In 1926 the Rolleston committee, made up of eminent doctors appointed by the government, recommended that physicians should be permitted to prescribe morphine or heroin for addicts (1) in cure by gradual withdrawal; (2) when drugs cannot safely be discontinued because of the severity of withdrawal symptoms; and (3) when the patient "while capable of leading a useful and relatively normal life when a certain minimum dose is regularly administered, becomes incapable of this when the drug is entirely discontinued."

These standards have been accepted and observed in the United Kingdom since 1926. The police function concentrates upon aiding doctors by preventing forged prescriptions and detecting frauds, such as an addict's placing himself in the care of more than one physician at the same time. In 1961 the Interdepartmental Committee on Drug Addiction, headed by Sir Russell Brain, reported that it saw no need for further statutory controls. In the early 1960s there were about 15 convictions annually in the courts of the United Kingdom for offenses involving opium (with sentences up to six months and fines up to £100), and about 50 annually for offenses involving manufactured drugs such as morphine and heroin (with sentences up to two years and fines up to £100). Home office records of known addicts, believed to be highly accurate because of prescription checks, show a total addict population consistently below 500, in a population exceeding 50,000,000. There is no significant smuggling activity, and no illicit drug market, in the United Kingdom.

NARDI, JACOPO (1476–1563), Florentine statesman and historian, whose history of his native city throws light on contemporary events and personalities, was born in Florence in 1476. A republican and supporter of Savonarola, he occupied various official positions after the expulsion of the Medici in 1494. He continued in the public service after their return, but joined in the movement for their second expulsion in 1527 and was instrumental in defeating the Medicean troops under Cardinal Silvio Passerini. On the family's final reinstatement in 1530, Nardi was exiled. He lived most of the rest of his life in Venice. He died in March 1563.

Nardi's chief literary work was his *Istorie della Citta di Firenze*, published posthumously (1582). Based on the diary of Biagio Buonaccorsi, a companion of Machiavelli, it covers the period 1498 to 1538. It reflects Nardi's republican zeal, and his admiration for the religious ideals of Savonarola, and its style is sometimes heightened by sincere feeling. He was also the author of two comedies, and of a life of Antonio Giacomini (1567).

See L. Arbib's complete edition of Nardi's *Istorie* (1838–41); A. Pieralli, *La vita e le opere di Jacopo Nardi* (1901).

NARDINI, PIETRO (1722–1793), Italian violinist and composer, was born at Leghorn on April 12, 1722. He studied violin and composition at Leghorn and later became a pupil of G. Tartini at Padua. For 15 years he held an appointment as solo violinist at the court of Stuttgart. In 1767 he settled at Leghorn and was with Tartini during the latter's last illness. He became music director to the duke of Tuscany in 1770 and enjoyed great fame as a performer and composer. He died at Florence on May 7, 1793. Nardini is remembered as Tartini's most famous pupil; he himself had many distinguished pupils, among them the Englishman Thomas Linley the younger. His compositions for the violin, although not numerous, are melodious, eminently playable, and also have considerable value as technical studies. Several of his sonatas and six of his quartets were reprinted in modern editions.

See K. Pfäfflin, *Pietro Nardini* (1936). (CS. CH.)

NARES, SIR GEORGE STRONG (1831–1915), English admiral and arctic explorer, was born in Aberdeen on April 24, 1831. Educated at the Royal Naval college, he entered the navy in 1845. For some years he served in the Pacific, after which he was mate of the "Resolute" in the arctic expedition of 1852 in search of Sir John Franklin. After serving in the Crimea, he was engaged in the training of cadets and in survey work off the northeast coast of Australia and in the Mediterranean. While in command of the "Challenger" (1872–74) he explored the southern oceans as far as the Antarctic and undertook extensive geographic and oceanographic work. In 1874 he commanded the arctic expedition to reach the north pole in the "Alert" and the "Discovery." The spring voyages of 1875 through the pack ice were difficult, costly and ill-fated. He was elected fellow of the Royal society (1875), created knight commander of the Bath (1876) and awarded medals by the Royal Geographical society (1877) and the Geographical Society of Paris (1879). In 1878 he commanded the "Alert" in a survey of the Magellan straits. Retiring from active service in 1886, he continued in the service of the government, becoming a vice-admiral in 1892. He died at Surbiton, Surrey, on Jan. 15, 1915.

His publications were *Reports on Ocean Soundings and Temperature* (1874–75) and *Narrative of a Voyage to the Polar Sea During 1875–76*, two volumes (1878).

See *Report of the Proceedings of the Arctic Expedition of 1875–1876* (1876). (H. G. Kg.)

NARESUAN (Phra Naret), popularly known as the Black Prince, was king of Siam from 1590 to 1605. In his youth, his country was invaded and conquered by Burma and was exposed to repeated invasions from Cambodia. In 1571, when only 16 years of age, Prince Naresuan was made governor of the northern province of P'itsanulok. His rule was a chronicle of constant fighting, during which he displayed reckless courage and extraordinary military skill. In 1584 he renounced allegiance to Burma. He successfully defended the capital city of Ayuthia, and defeated the besieging Burmese forces by a combination of scorched earth and daring guerrilla tactics. He also drove out the Cambodians and thus had reassured Siamese independence by the time he mounted the throne. As king he devoted more time to the improvement of internal affairs. He conducted peaceful relations with Portuguese from Malacca and Spanish from Manila. Then he expanded his power over much of Burma and Malaya, and reduced Cambodia to vassalage. He re-established the prestige of Siam in the region between the Indian ocean and the borders of China. More than anyone else, the celebrated warrior hero was responsible for the greatness of Siam which dazzled the first East India merchants from the Netherlands and Elizabethan England. *See* also Thailand: *History*. (C. A. B.)

NARIÑO, southwesternmost department of the republic of Colombia, bounded by Ecuador on the south, the Pacific ocean on the west, and by the department of Cauca and the *comisaria* of Putumayo on the north and east. The *comisaria* of Putumayo was made a part of Nariño in 1953 and re-established as a *comisaria* in 1957. Area, 12,499 sq.mi. The population of Nariño (547,323 in 1951; [1961 est.] 613,640) is principally concentrated in the volcanic Andean highlands above 5,000 ft. Indian physical and cultural characteristics predominate but Spanish is the universal language. The densely settled *altiplano* of Túquerres-Ipiales on the Ecuador frontier is separated by the Patía river from that of Pasto, where Nariño's capital of that name is located. The economy of Nariño is based almost entirely on agriculture. Wheat, barley, beans and potatoes are the principal highland crops. Bananas are exported from the port of Tumaco, which handles large ocean-going vessels. A railroad from Tumaco ascends the Patía valley for 70 mi. to El Diviso. (Js. J. P.)

NARMADA (Narbada), a river of central India. It is sometimes regarded as the boundary between Hindustan or northern India and the Deccan or peninsular India. It rises near Amarkantak in the Maikala range in Madhya Pradesh and for the first 200 mi. of its course winds among the Mandla hills. Then at Jabalpur, passing through the Marble Rocks (noted dolomitic marble gorge, about 2 mi. long), it enters the structural trough between the Vindhya and Satpura ranges, and pursues a direct westerly course to the Gulf of Cambay. Its total course through Madhya Pradesh and Gujarat is 801 mi., and it flows into the sea in the district of Broach. It receives the drainage of the northern slopes of the Satpuras, but not that of the Vindhya tableland, the streams from which flow into the Ganges and Jumna. After entering Gujarat state, the river widens out in the fertile district of Broach, with an average breadth of ½ to 1 mi. Below Broach city it forms an estuary which is 13 mi. broad where it enters the Gulf of Cambay. The Narbada is nowhere utilized for irrigation, and navigation is confined to the lower section. In the rainy season boats of considerable size sail about 60 mi. above Broach city. In sanctity the Narbada ranks second to the Ganges among the rivers of India, and along its whole course are special places of pilgrimage such as Suklatirtha and Nemawar. The most meritorious act that a pilgrim can perform is to walk from the sea to the source of the river and back along the opposite bank. The valley of the Narbada has always been an important routeway between the Arabian sea and the Ganges valley. Its middle section is followed by the main railway from Bombay to Jabalpur on its way to Allahabad. (L. D. S.)

NARODNIKI (Populists), the adherents of a 19th-century socialist movement in Russia based on the idea that political propaganda among the peasantry would lead to the awakening of the masses and, through their influence, to the liberalization of the regime. Since Russia was a predominantly agricultural country the peasants represented the majority of the people (*narod*); hence the name of the movement, *narodnichestvo* or populism.

The movement arose among the Russian intelligentsia (*i.e.*, professional people, students and the so-called *raznochintsi* or intellectuals not belonging to the gentry) in the 1860s; it gained momentum in the 1870s and culminated in the assassination of the emperor Alexander II in 1881. It was enhanced by dissatisfaction with Alexander's land reforms of 1861, which, though liberating the peasants from serfdom, created unsatisfactory economic conditions for peasant agriculture by favouring the landowners in the partition of land and by imposing an involved system of collective compensation on the villages. At the same time the movement was influenced by western ideas; *e.g.*, those of Herbert Spencer, Auguste Comte and John Stuart Mill.

The Narodniki also embodied in their teachings a considerable amount of Communist ideology gathered from Karl Marx's works, accepting for instance his ideas of communal ownership and production, his dislike for private enterprise and his definition of surplus value. However, they modified two of Marx's fundamental principles, thus bringing upon themselves the criticism of orthodox Marxists. First, they believed in agrarian communism and disregarded the industrial proletariat, which in their days represented but a small minority of the population of Russia. Second, they adapted to their needs Marx's theory of historical development, according to which human society must progress inevitably from primitive communism to industrial capitalism and thence to the dictatorship of the proletariat. That, the Narodniki argued, would not apply to Russia, where peasant life was traditionally organized in the *mir* or village community. A successful change of regime would, in their view, allow Russia to skip the intermediate stages and pass straight from primitive communism to modern socialism. Thus, like so many Russian doctrines, populism embodied a messianic element reminiscent of certain teachings of the earlier Russian nationalist philosophers, the Slavophils, who also believed in the inherent virtues of the peasant commune. Yet an evolution of thought did take place. While the Slavophils idealized the *mir* as an ancient and peculiarly Slavonic institution, the Narodniki laid stress on social questions.

The economic theories of the Narodniki were vague. Unlike the Marxists, they did not distinguish between the various income groups of the peasantry and did not class the richer peasants as enemies of the people. The *mir* and the *artel* (a primitive village productive co-operative), they believed, would naturally evolve a system of production and distribution beneficial to the community.

On the political methods whereby reforms and the drafting of a constitution should be achieved, the Narodniki differed widely

among themselves. The moderates believed that propaganda among peasantry would undermine the tsarist regime and enforce a democratization of the government, but there was disagreement as to how this would take place. On the one hand M. A. Bakunin, the anarchist of the older generation of idealistic socialists, put his hopes into peasant risings the sheer force of which would, he believed, effect political changes; on the other, the moderate P. L. Lavrov (1823–1900) advocated propaganda among the people and the enlightenment of the illiterate peasantry, which would lead to gradual reforms. In opposition to both those theories the radical P. N. Tkachev (1844–85) preached a forcible overthrow of the tsarist regime followed by gradual education of the masses to communist standards: until such time as the people were enlightened enough to govern, Tkachev suggested the rule of an intellectual minority which would guide them to this goal. The Narodniki were predominantly atheist in their philosophical outlook and positivist in their method and claimed to accept only phenomena confirmed by experience.

The activities of the Narodniki developed in the late 1860s in a movement known as *khozhdenie v narod* ("going to the people") in the course of which young intelligentsia, dressed in peasant clothes, canvased rural regions, mainly those of the Volga, Don and Dnieper. This led to persecution, arrests and political trials, the most famous one of which was the "trial of the 193" (1878). The illiterate peasantry did not always respond to propaganda in the expected way and sometimes gave the dedicated intellectuals away to the police. This campaign and its outcome have been well described by Ivan Turgenev in his novels.

The Narodniki retaliated to persecution by acts of counter-violence and by the "execution" of *agents provocateurs*. In 1876 a secret organization, the *Zemlya i Volya* ("Land and Freedom"), was formed, and the Narodniki started switching over from peaceful propaganda to terrorist and conspiratorial activities.

Differences between moderates and radicals widened and, in 1879, at the Voronezh party meeting, the movement split. The moderates, G. V. Plekhanov and P. B. Axelrod (1850–1928), then formed the organization *Cherny Peredel* ("Black Redistribution") which, as the name indicates, aimed at a fairer distribution of land among the peasantry. The radicals, A. I. Zhelyabov (1850–81), A. D. Mikhailov (1855–84), Vera N. Figner and Sofia L. Perovskaya (1853–81), gathered around *Narodnaya Volya* ("People's Will"), a terrorist organization which set out to change the regime by violence. A series of political murders was arranged, culminating, on March 13 (N.S.), 1881, in the assassination of the emperor Alexander II, accompanied by the party's open letter to his successor demanding constitutional reforms.

This was the climax of the activities of the *Narodnaya Volya* organization, which thereafter deteriorated. The 20th-century Socialist Revolutionary party can be called the ideological descendant of the Narodniki. In the 1880s Plekhanov became the head of a Marxist group, *Osvobozhdenie Truda* ("Liberation of Labour"), and an outstanding theorist of Social Democratic thought.

NARRA (ASANÁ), the local Philippine name applied to certain timber trees of the genus *Pterocarpus* of the pea family (Leguminosae), especially to *P. indicus*, also called India padauk. Narra wood is used for cabinet work; it is usually a red or rose colour, often variegated with yellow, and is hard and heavy. The trunk is surrounded (or, occasionally, supported) by huge buttresses extending outward and upward for 10 to 20 ft.; these are sometimes made into table tops, the pattern of the grain and the colouring being hardly equalled by any other timber. The wood cells contain a peculiar substance: a minute chip placed in a bottle of water soon gives an opalescent colour to the liquid. Narra wood is known also as Burmese rosewood, Andaman redwood and Kiabooca wood.

NARSES (*c.* 478–*c.* 573), Byzantine general, born in Persarmenia, was a eunuch who played an important role during Justinian I's reign. He became an official in the imperial household (*sacellarius*) which entailed command of the spatharocubiculars (a bodyguard of eunuchs), eventually rising to be grand chamberlain (*praepositus sacri cubiculi*). When the Nika riot broke out in Constantinople in 532, Narses was one of those who saved Justinian his throne in winning over the Blue political faction by lavish distribution of bribes and by timely military action. In 535 he was sent to Alexandria with troops to ensure the reestablishment of the imperial candidate Theodosius as patriarch and to quell disturbances which had arisen by reason of the election. In 538 he took part in Justinian's reconquest of Italy ostensibly to assist Belisarius. The two commanders, very different in character, found it difficult to co-operate and in 539 Narses was recalled to Constantinople. In the summer of 551 Narses was in charge of troops directed against barbarian raiders, mainly Huns, Gepids and Lombards, who were devastating the Balkans. On the resurgence of Ostrogoth power in Italy under Totila, Narses was made commander in chief in the autumn of 551, and in the following year opened a vigorous campaign. At the end of June in 552 he defeated Totila, who died of his wounds, and he entered Rome. During the following years scattered resistance by the Goths was crushed, and Franks and Alamans entering north Italy were subdued. Imperial control was gradually restored under Narses, who appears to have exercised both civil and military authority. He was recalled by Justin II in 567 and is said to have retaliated by inviting the Lombards to enter north Italy.

In appearance he was small and elegant, and as a eunuch could never be a candidate for the imperial throne, which may have been one reason for the continuous favour he enjoyed from Justinian. He was a devout man and during the empress Theodora's lifetime he seems to have inclined toward Monophysitism. Though apparently not a particularly cultivated man, he had moral and intellectual qualities. Astute, controlled, with excellent judgment, he served Justinian well, and his evil reputation for oppression and avarice in Italy during his later years should not obscure this.

NARSIMHAPUR (NARSINGHPUR), is a town and district in the Jabalpur division of Madhya Pradesh, India. The town, headquarters of the district, lies on the Central railway 50 mi. W. of Jabalpur. Pop. (1961) 17,940. Once called Chhota Gadarwara, it was renamed Narsinghpur when a temple of Narsingh (the "man lion," an incarnation of Vishnu) was erected about 150 years ago. The river Singri divides the town into two parts, Kandeli on the east and Narsimhapur on the west. The chief trade is in timber.

NARSIMHAPUR DISTRICT (area 1,979 sq.mi.; pop. [1961], 412,406) is a narrow strip of fertile black alluvium between the Narmada (Narbada) river and the Satpura ranges. The Narmada, which marks its northern border, receives many tributaries from the south whose ravines are an ever-growing problem. Much of the district is forested and the remainder is under cultivation, the main crops being wheat, cotton, jowar millet and sesamum.

Narsimhapur once formed part of the territory of the Mandla Gond kings of Chauragarh, 20 mi. S.W. of Narsimhapur town. Later, the Bundelas of Orchha conquered Chauragarh and in 1781 the Gond dynasty was overthrown by the Marathas who were ousted by the British in 1818. (S. M. A.)

NARTHEX, in architecture, a long, narrow porch, usually colonnaded or arcaded, at the entrance of a church, sometimes alone, sometimes as the side of the atrium (*q.v.*) adjacent to the church façade. In the early days of Christianity it was the only portion of the church to which catechumens and penitents were admitted. Occasionally an additional vestibule exists within the church building proper. In this case, the inner vestibule is called the narthex and the outer porch an exonarthex. The narthex is common in basilican, Byzantine and some Romanesque churches, particularly in Italy; in the Gothic period its use had almost disappeared, but during the Renaissance it was again found, although its ritual usage had entirely died out and it had become a simple

porch or vestibule. *See* BASILICA; RELIGIOUS ARCHITECTURE.

NARVA, a river port of the Estonian Soviet Socialist Republic, U.S.S.R., situated on the Narva (Narova) river a few miles above its entry into Narva bay on the Gulf of Finland and 120 mi. E. of Tallinn on the Tallinn-Leningrad railway. With it is associated the nearby seaside resort of Narva-Joesuu. Its population, mostly Russian immigrants, was 27,600 in 1959.

The town is dominated by two medieval fortresses—Ivangorod on the east bank built by the Russians and Hermann fortress on the west bank founded by the Danes. In the 13th century a settlement developed under the protection of the Danish fortress and obtained city privileges. In 1346 the Danish king, Valdemar IV, sold Narva to the Teutonic knights whose stronghold it remained until its capture in 1558 by the Russians. In 1581 it was taken by the Swedes who lost it in 1704 when the Russian emperor, Peter the Great, took it from Charles XII by assault after having suffered a great defeat under its walls four years earlier. Narva remained under Russian rule until Estonia obtained independence in 1918–20; it was annexed by the U.S.S.R. with the rest of Estonia in 1940–41. During World War II it was occupied by the Germans (1941–44) and it suffered much from artillery fire when it was recaptured by the Soviets. In 1945 the suburb of Ivangorod (Jaanilinn) was incorporated into Leningrad *oblast* of the Russian Soviet Federated Socialist Republic.

Narva is an important textile centre, the site of the large Kreenholm mills. In 1955 a hydroelectric power station with a capacity of more than 100,000 kw. was completed on the Narva river. To the west at Soldina is a huge Baltic electric power station run by shale oil.

NARVÁEZ, PÁNFILO DE (*c.* 1480–1528), Spanish adventurer, was born at Valladolid. He helped Diego Velásquez in the reduction of Cuba and was put at the head of the force sent to the Aztec coast to compel Hernán Cortés to renounce his command. He was defeated by his compatriot and made prisoner (1520).

On his return to Spain Narváez obtained from Charles V a grant of land in Florida as far as the River of Palms. Landing near Tampa bay in April 1528, he struck inland with 300 of his followers and reached "Apalache" on June 25. Disillusioned in their hopes of fabulous wealth, they made for the coast, arriving in July at the Bahia de los Caballos, at or near St. Mark's. Having built rude boats, the much-reduced company sailed on Sept. 22 for Mexico, but the vessel that carried Narváez was destroyed in a storm. His lieutenant, Nuñez Cabeza de Vaca, and three others ultimately reached the Gulf of California by way of Texas. *See* FLORIDA.

NARVÁEZ, RAMÓN MARÍA (1800–1868), DUQUE DE VALENCIA, Spanish general and politician, a leading Conservative supporter of Isabella II, was born at Loja (Granada) on Aug. 5, 1800, of an illustrious Andalusian family. He joined the Guardias Valonas in 1815 and was one of the ablest of the regent María Cristina's military leaders during the first Carlist war. He rose to the rank of brigadier in 1836 and began his political career with election to the *Cortes* in 1838. An opponent of Gen. Baldomero Espartero (*q.v.*) and the Progresista party, Narváez led an unsuccessful rising at Seville in 1838 and had to flee, first to Gibraltar and then to France. There he plotted against Espartero, especially after María Cristina (*q.v.*) had been driven from the regency.

In 1843 he staged a successful *coup d'état* in Spain and the next year was asked to form a government. Narváez's first ministry was notable for the promulgation of the 1845 constitution and for the tax reforms of the finance minister, Alejandro Mon. The government fell early in 1846 and Narváez was replaced first by the marqués de Miraflores and then, after a brief return to office, by Francisco Istúriz, who offered him the post of ambassador to Naples. Narváez refused this appointment and went into exile, but Joaquín Pacheco's government made him ambassador to France, whence he returned in 1847 to head another ministry. The new administration (Oct. 1847–Jan. 1851) was Narváez's period of greatest achievements—including the suppression of a fresh Carlist rising and the execution of numerous public works. He retired from politics in 1851, but returned briefly to power in 1856–57, 1864–65 and 1866. He died in Madrid on April 23, 1868. He was created duque de Valencia in 1844.

NARVIK, an ice-free seaport on the Ofotfjord in the northern part of Nordland *fylke* (county), Norway, 110 mi. N.E. of Bodø. Pop. (1960) 13,219. The iron ore store and the railway divide the town into two districts: Frydenlund, with the slate church (1925), hospital, college and primary schools; and Oskarsborg, with the marketplace, market hall, Kongens gate (main street), town hall, technical schools and a cableway ascending 2,100 ft. above the town toward the top of the Fagernesfjell (4,186 ft.). A railway links Narvik with Kiruna and other places in Sweden. Narvik is connected with other parts of Norway by roads, coastal shipping and airlines. The main occupation of the inhabitants is the export of iron ore, brought from the Kiruna-Gällivare region in Sweden. The town dates from the 1880s (it was called Victoriahavn, 1887–98, in honour of the crown princess Victoria, wife of crown prince Gustavus, later Gustavus V, and of the princess royal Victoria of Great Britain, wife of Frederick III of Prussia), and developed after the construction of the Ofot railway (opened 1903), the most northerly in the world. During World War II the Germans seized Narvik on April 9, 1940. Two naval battles were fought there on April 10 and 13, 1940, and the port was captured on May 28 by a British-French expeditionary force which withdrew on June 9. (A. L. So.)

NARWHAL (NARWAL, NARWHALE), one of the toothed whales (*Monodon monoceros*) of the Arctic in which the left of the two teeth present (very rarely both) is developed in the male as a long unicornlike, forward-directed tusk (which may be in excess of nine feet), twisted in a left-handed spiral. The body, which reaches about 15 ft. in length, is gray, mottled with darker and lighter markings, and has no dorsal fin; the head is bluntly rounded in profile. The right tooth of the male, generally, and both teeth of the female, usually, remain unerupted in deep sockets in the skull. In young narwhals several small teeth are present but disappear soon after birth.

The narwhal is rarely found south of latitude 65° N.; it is gregarious and usually found in schools of 15 or 20, sometimes many more. Its food consists of squid and fishes, in the capture of which it appears to be in no way handicapped by its reduced dentition. Little is known of the biology of the narwhal. The use of the tusk to the animal is unknown and its value as ivory to man is not great because it contains a central cavity that precludes its use in the manufacture of anything but small articles. *See* also WHALE. (L. H. M.)

NARYN, a river and town in Soviet Central Asia. The river flows westward for 431 mi. (694 km.) from the Tien Shan to the Fergana valley where it joins the Syr-Darya. It crosses the Uzbek and Kirgiz Soviet Socialist Republics, and although the winters are cold it does not freeze and has a large hydroelectric potential. The first of a series of power stations to be built on the Naryn and its tributaries was completed near Uch-Kurgan on the border of the Uzbek S.S.R. in Nov. 1962, and generates 180,000 kw.

The town (pop. [1959] 15,000), in the Kirgiz S.S.R., was founded by the Russians as a fortified outpost in 1868. It lies at the point where the motor road from Frunze to the Torugart pass crosses the river, and is 110 mi. S. by road of the railway station at Rybachye. (G. E. WR.)

NARYSHKIN, a Russian family which gave its name to the faction contending for the Russian throne on behalf of Peter Alekseevich (later Peter I the Great) against the Miloslavskis, who represented the interests of Ivan Alekseevich (Ivan V).

The Naryshkins sprang into prominence and entered the closed circle of the Kremlin aristocracy with the marriage in 1671 of the tsar Alexis (*q.v.*), after the death of his first wife M. I. Miloslavskaya, to Natalia Kirillovna Naryshkina (1651–94). When, in 1672, Natalia gave birth to Peter, a sturdy child—unlike Alexis' two sons by Miloslavskaya, the sickly Fedor and the halfwitted Ivan—the fortunes of the Naryshkins rose and those of the Miloslavskis declined. In the next 20 years eight Naryshkins were to be elevated to the dignity of boyar. The actual leader

of the Naryshkin party was A. S. Matveev (*q.v.*): related to them through a niece of his by marriage, he had also been Natalia's guardian and brought about her marriage with Alexis.

On the accession of Miloslavskaya's elder son to the tsardom as Fedor III (*q.v.*) in 1676, the Miloslavskis regained their ascendancy and prevailed on the tsar to banish Matveev and his family. During his disgrace, Natalia won the support of many powerful families and some of the higher clergy, including the patriarch of Moscow, Ioakhim, who in 1682, on Fedor's death, proclaimed Peter tsar in accordance with the wish of the vestigial *zemski sobor* (land assembly). To mark the occasion, six Naryshkins were at once promoted grooms of the bedchamber (*spalniki*).

Meanwhile the discontented *streltsy* (musketeer troops) were threatening revolt, and the Miloslavskis deftly presented them with a collective scapegoat in the persons of the Naryshkins. From May 25 (new style; 15 old style), 1682, for a whole week, the *streltsy* wreaked death and destruction on the persons and possessions of their true and imaginary enemies. Among their victims were Matveev and three Naryshkins; a rumour circulated by the Miloslavskis had accused them of plotting to murder Peter's half brother Ivan, the *streltsy's* own candidate for the throne. On June 5 (N.S.), Ivan and Peter were proclaimed joint rulers, with Ivan's sister Sophia (*q.v.*) as regent. Natalia's father, Kiril Poluektovich Naryshkin (1623–91), and her brothers Lev Kirillovich (1664–1705) and Martemyan Kirillovich (1665–92) were all banished.

Time, however, was on the side of the Naryshkins. While Natalia, counseled by B. A. Golitsyn (*q.v.*), managed to hold her own, Peter was growing up. In the spring of 1689, thanks to V. V. Golitsyn's absence in the Crimea, the Naryshkins, including Lev (who had been allowed to return from exile), were able once more to seize the initiative. It was now their turn to expose a plot being hatched by the Moscow *streltsy*, whose commander, F. L. Shaklovity, was openly accused of conspiring to wipe out the Naryshkin family. Tension reached its climax in August, when Peter, hearing that the *streltsy* were after his blood, sought sanctuary in the Troitse-Sergiev monastery, where he was joined by the Naryshkins and growing numbers of his supporters. By the end of the first week in September, Sophia threw her hand in, leaving the Naryshkins, especially Lev and Natalia, and their adherents in control. In 1690 Lev Kirillovich was appointed head of the foreign office (*posolski prikaz*), a post which he occupied until 1702, though he had ceased to exercise any political influence by 1699.

See C. Bickford O'Brien, *Russia Under Two Tsars, 1682–1689* (1952). (L. R. Lr.)

NASBY, PETROLEUM V., pen name of David Ross Locke (1833–1888), U.S. humorous satirist of the Civil War period. He was born near Binghamton, N.Y., on Sept. 20, 1833. From an early age he worked for various newspapers in New York and Ohio. In 1861, as editor of the *Findlay* (Ohio) *Jeffersonian*, he published the first of many satirical letters purportedly written by one Petroleum Vesuvius Nasby. For over 20 years Locke contributed "Nasby Letters" to the *Toledo Blade*, which under his editorship gained national circulation. Many of the letters appeared also in book form.

An ardent Unionist and foe of slavery, Locke vigorously supported the Northern cause. His chief weapon was a heavy irony. He let his character Nasby, a "Copperhead," argue in favour of the Southern position; but because Nasby is stupid, illiterate, coarse and vicious, he damns the cause he favours. His reasoning is absurd, his grammar and spelling atrocious. Used for a serious end, such verbal fooling delighted Northern readers, including President Lincoln, who occasionally read Nasby letters to his cabinet. But topical satire and humour date quickly. Among the many humourists who flourished during and immediately after the Civil War, Locke, perhaps the most influential of his time, is today one of the least readable. He died on Feb. 15, 1888.

See Cyril Clemens, *Petroleum V. Nasby* (1936); Walter Blair, *Horse Sense in American Humor* (1942). (L. T. D.)

NASCIMENTO, FRANCISCO MANOEL DO (pseudonym, Filinto Elísio) (1734–1819), the last of the Portuguese neoclassical poets. He was born in Lisbon on Dec. 23, 1734, of humble and probably adulterous origin. He was educated by the Jesuits and ordained in 1754. Not long afterward he founded a literary society known as the *Grupo da Ribeira das Naus*. In 1768 he became tutor to the daughters of the marquis of Alorna and fell in love with one of them, the "Maria" of his poems. Disapproving of the low-born poet's affection for his daughter, the marquis may have been ultimately responsible for Nascimento's being denounced to the Inquisition in June 1778. He succeeded in escaping to France, however, and there, except for some four years in The Hague during the revolutionary Terror, he remained, living by translations and by taking private pupils. But when he died, in Paris on Feb. 25, 1819, it was recognized that Portugal had lost its foremost poet.

The themes of Nascimento's poetry, which is usually in blank verse, polished, robust but often overladen with archaisms, range from denunciations of the tyranny of the aristocracy, the Inquisition and the hierarchy, coupled with praise of liberty and patriotism, to homely evocations of the joys of life in his native land and laments on the poverty and loneliness of exile. His demonstration of the flexibility and richness of the Portuguese language, his choice of themes and his translations of such works as Wieland's *Oberon* and Chateaubriand's *Les Martyrs* influenced the romantic writers. For portrait *see* article Portuguese Literature.

Bibliography.—*Obras completas de Filinto Elísio*, 22 vol. (1836–40); a useful selection is that edited by J. P. Tavares (1941). *See* also J. M. Pereira de Silva, *Filinto Elísio e a sua época* (1891); T. Braga, *Filinto Elísio* (1901). (N. J. L.)

NASEBY, BATTLE OF, was fought on June 14, 1645, about 20 mi. S. of Leicester, between the parliamentarian army and the royalists under Prince Rupert; it largely decided the first phase of the English Civil War (*see* Civil War, English). Sir Thomas Fairfax, commander in chief of the parliamentarian New Model army that had been formed earlier in 1645, had ultimately been given a free hand on strategy and had made up his mind to attack the main royalist army whose headquarters were at Oxford. Oxford had long been under siege. To relieve the pressure the royalist army broke out and stormed Leicester on May 30, but afterward Charles I was uncertain what to do next and his army lingered at Daventry, in Northamptonshire, collecting supplies. Fairfax advanced to Kislingbury, 8 mi. E. of Daventry, on June 12. On June 14 the king's council of war decided it must accept a battle.

The two armies drew up and faced each other on a one-mile front. The royalist army was deployed along a ridge called Dust hill, the parliamentarian army on another ridge half a mile away; between them lay a valley known as Broad Moor, lying about a mile north of Naseby. Prince Rupert had approximately 10,000 men under his command; the parliamentarians about 14,000. Rupert himself commanded the cavalry on the royalist right, Lord Astley the infantry in the centre and Sir Marmaduke Langdale the cavalry on the left. Facing them were, respectively, the parliamentarian cavalry under Commissary General Henry Ireton, the infantry under Maj. Gen. Philip Skippon and the cavalry on the right under Fairfax and Lieut. Gen. Oliver Cromwell. In spite of his inferior numbers Rupert attacked all along the line. He himself drove back the horse on Ireton's left but then made the mistake of engaging in a wild pursuit; Ireton himself harassed the royalist infantry but soon was wounded and taken prisoner. Meanwhile on the right Fairfax' first line of horse repulsed the royalists. Fairfax himself then went to rally the infantry in the centre and handed over the cavalry command to Cromwell. Unlike Rupert, Cromwell successfully regrouped his troopers and was thus able to go to the help of the parliamentarian foot, who were hard pressed in the centre where Skippon had been wounded. At this stage Charles I, who had a small reserve in hand, wanted to commit it to redress the course of the battle, but was prevented from doing so, and in the confusion the opportunity was missed. By the time Rupert and his men returned from attacking the parliamentarian baggage train near Naseby village, the battle was

virtually over. The parliamentarians claimed to have killed between 400 and 1,000 men, to have taken 4,500 prisoners, and to have captured arms for 8,000 men, while themselves losing only 150 men.

The inferiority of the royalists in numbers and in morale after three years of war chiefly explains the victory. But Rupert's inability to keep his troopers in check, which contrasted with Cromwell's fine discipline of his cavalry, contributed notably to the royalist defeat. The attacks on the royalist infantry's flanks by Ireton and by Cromwell had saved the weakened parliamentarian centre. Fairfax, unlike Rupert, exerted considerable control over the course of the battle and, together with Cromwell, deserved the triumph.

See Austin Woolrych, ***Battles of the English Civil War*** (1961). (M. P. A.)

NASH, JOHN (1752–1835), English architect best known as architect to the prince regent, later George IV, was born in London, son of an engineer and millwright. Starting his career in the office of the architect Sir Robert Taylor, Nash remained there for about ten years. In 1778 he set up in business as architect and builder but in 1783 became bankrupt through speculation and moved to make a fresh start in Carmarthen. Various moderate commissions followed, including jails at Carmarthen, Cardigan and Hereford. He became well established as a country-house architect, designing freely in adaptations of the classical, Gothic and picturesque "cottage orné" styles. Surviving examples of his houses include Llanayron, Cardiganshire; Southgate grove, Middlesex; Sundridge park, Kent; Blaise hamlet, near Bristol; and Cronkhill, Shropshire.

In about 1796 he returned to London and soon entered into informal partnership with Humphrey Repton, the landscape gardener. From the time of his marriage in 1798, Nash seems to have acquired the patronage of the prince regent and also a reasonable fortune, enabling him to remodel and live in a town house, 29 Dover street, and to build himself East Cowes castle, Isle of Wight, in semi-baronial manner.

His major work, begun in 1811, was the development of Regent's park and Regent street as a residential area, linked by a new street to Carlton house and the centre of Georgian London. It incorporated the Regent's canal, churches, artisans' houses, shops and arcades as well as the layout of many of the surrounding streets. Regent street with its well-known Quadrant and colonnades, the latter demolished in 1848, was finished in about 1825 by which date Nash had also built the circular porticoed Church of All Souls, Langham place. These schemes of town planning with their appreciation of the picturesque and skilful use of urban composition on a large scale still provide many of London's most charming features such as Park Village East, Park crescent and Carlton House terrace.

From 1813 to 1815 Nash held the post of deputy surveyor general; he had also become the prince regent's personal architect in which capacity he extended and greatly altered the Royal pavilion, Brighton (1815–23), in a fanciful "Hindoo" style at enormous total cost of about £160,000. In 1821 instructions were given that Buckingham house should be rebuilt as a royal palace, again regardless of expense. The king, however, died in 1830 and Nash's work at Buckingham palace was never completed as he shared his master's unpopularity and was dismissed. Subsequently, in 1831, he was required to answer an inquiry into the expenditure and alleged defects of the building. He died at Cowes on May 13, 1835.

See J. N. Summerson, ***John Nash*** (1935). (E. C. D.)

NASH, PAUL (1889–1946), English painter appointed an official war artist in both World Wars I and II, was born in London on May 11, 1889, and studied at the Slade school, London. In 1914 he enlisted in the artists' rifles and his 1918 exhibition of paintings portrayed with abstract detachment shattered war landscapes, such as "Menin Road" (Imperial War museum, London). There followed seascapes ("Wall Against the Sea," Carnegie institute, Pittsburgh) and landscapes ("Oxenbridge," Birmingham art gallery, Eng.) of distinguished design and cool, vibrating colours; and book illustrations and wood engravings. In the 1930s his paintings developed freer design and richer colour, together with a symbolic, "fourth-dimensional" vision influenced by surrealism. One of his best-known paintings of World War II was "Totes Meer" ("Dead Sea," Tate gallery, London). Later paintings reveal his imaginative poetic symbolism; *e.g.*, "November Moon" (Fitzwilliam museum, Cambridge, Eng.) and "Solstice of the Sunflower" (National gallery, Ottawa). Nash died at Boscombe, Hampshire, on July 11, 1946.

See Paul Nash, ***Outline*** (1949); M. Eates (ed.), ***Paul Nash*** (1948). (M. T. N.)

NASH, RICHARD (1674–1762), first of the great dandies of England, known as BEAU NASH, and also as "Monarch of Bath and Tunbridge Wells." He was born of upper-middle-class Welsh parents on Oct. 18, 1674, at Swansea, where his father, reduced by Cromwell's wars, was operating a bottle factory. Young Nash, after Carmarthen grammar school and a year at Jesus college, Oxford, bought his way into the guards as an ensign. Introduced thereby to London society, he "put his whole intellect into a bow." When army pay proved insufficient he entered at 20 the Inner Temple, less to study law than "the art of living without money." Over the gaming tables Nash rounded his manner. The epicures dubbed him "the Count" and the benchers chose him master of the revels on the accession, singly, of William III in 1695. Capt. (afterward Sir) John Vanbrugh, to depict a beau, modeled from Nash the title part of the comedy *Aesop* (1697).

When Queen Anne passed a month at Bath, she drew thither the nobility, who in turn attracted gamblers, among them, in 1705, Beau Nash. He gained the patronage of the manager, Captain Webster, who was soon afterward killed by a duelist. Bath corporation thereupon elected Nash master of ceremonies. He elevated the standard of manners by forbidding swords, boots and aprons in assemblies; he regulated chair-men; he fixed charges for lodgings. Improving Bath itself, he built roads, promoted assembly rooms and founded a mineral-water hospital with 108 beds for the poor. In 1715 the Beau began opening the season in Tunbridge Wells and controlled the resort from 1735, when its manageress died. Three years later he entertained the prince of Wales at Bath. Nash wore a large white three-cornered cocked hat, dressed elaborately and traveled in royal manner in a coach-and-six. Lord Chesterfield said many in the ballroom took the gold-laced master, at a distance, for "a gilt garland." Unmarried, he was egoistic and flippant, though openhanded, and excelled as a mediator. After 1745 antigambling laws ruined his livelihood. Nash died at Bath on Feb. 3, 1762, a threadbare pensioner, but was buried with pomp in Bath abbey.

NASHE (NASH), **THOMAS** (1567–1601?), English pamphleteer, poet and dramatist, was born in 1567 at Lowestoft, Suffolk, the son of a Herefordshire minister. In 1581 or 1582 he matriculated at St. John's college, Cambridge. About 1588 he left Cambridge and went to London, where he became associated with Robert Greene and other professional authors. His first appearance in print was his preface to Greene's *Menaphon* (1589), though he probably wrote *The anatomie of absurditie* (1589) earlier. Both works reveal the recent university graduate: a fervid but traditional espousal of literary standards, violent hostility to popular literature, a conventional misogynic attitude and a style tainted by euphuism. The learning is pretentious and the tone often arrogant and sometimes coarse: "I will persecute those idiots and their heires unto the third generation, that have made Art bankerout of her ornaments, and sent Poetry a begging up and downe the Countrey."

In 1589 and 1590 he evidently became a paid hack of the episcopacy in the Marprelate controversy (*q.v.*), and matched wits with the unidentified, but enormously clever, "Martin." Almost all the replies to Martin have variously been assigned to Nashe, but the only one that has been convincingly attributed is *An Almond for a Parrat* (1590). He wrote the preface to Thomas Newman's unauthorized edition of Sir Philip Sidney's *Astrophel and Stella* (1591). Though Nashe penned an extravagant, servile

dedication to Sidney's sister, the countess of Pembroke, the book was withdrawn and reissued in the same year without Nashe's foreword.

Pierce Penilesse his supplication to the divell (1592) revealed Nashe's artistic strengths and weaknesses. Purged of euphuistic affectations, his prose had become a combination of colloquial diction and idiosyncratic coined compounds ideal for controversy and for his eccentric discussion of the seven deadly sins. But verbal facility was frequently an end in itself; Nashe rambled, inserting whatever came to mind, and failed to impose a consistent structure upon his material. In a digression he attacked Richard Harvey and thus added to Greene's diatribe against the Harveys in *A quip for an upstart courtier* (1592) a passage which Greene deleted before his death on Sept. 3, 1592. After Gabriel Harvey (*q.v.*) had assailed both Greene and Nashe in *Four Letters and certaine sonnets* (1592), in *Strange newes* (1592), Nashe defended, but not too strenuously, the memory of his friend and heaped further abuse upon the Harvey family. Then, in the foreword to *Christs teares over Jerusalem* (1593), he indicated willingness to end the dispute, but when Harvey, who was probably unaware of the proposal, printed *Pierces supererogation* (1593), Nashe withdrew the preface in the second edition, and wittily burlesqued his opponent in *Have with you to Saffron-Walden* (1596). Thomas Middleton, writing in 1604, was probably most accurate when he termed this controversy "but the running a tilt of wits in booksellers' shops on both sides of John of Paul's churchyard." For in 1592 and 1593 Harvey was in the employ of John Wolfe, who printed his pamphlets, and, if Harvey is to be credited, Nashe was as early as 1593 a hack in the printing establishment of John Danter. The flyting was officially terminated in 1599, when the archbishop of Canterbury ordered "that all Nasshes bookes and Doctor Harveyes bookes be taken wheresoever they maye be found and that none of theire books bee ever printed hereafter."

Apparently Nashe wrote *Strange newes* while he was living in late 1592 and early 1593 at the home of Sir George Carey, who dramatically relieved for the moment his oppressive poverty. *Christs teares over Jerusalem* and *The Terrors of the Night* (1593) were dedicated to members of the Carey family. In the former Nashe ominously warned his countrymen during one of the worst plagues that unless they reformed London would suffer the fate of Jerusalem, and so strenuously condemned the greed of London merchants that he was forced to cancel the offending passage. *The Terrors of the Night* was a discursive, sometimes bewildering, attack on demonology. Both works were medieval in their attitudes and almost puritanical in their moral indictments.

Pierce Penilesse excepted, Nashe's most successful works were his masque, *Summers last Will and Testament* (1592, publ. 1600), his novel *The unfortunate traveller, or, The life of Jacke Wilton* (1594) and *Nashes lenten stuffe* (1599). *The unfortunate traveller* has brilliant sections, including the romance of the earl of Surrey and Geraldine, but it is marred by Nashe's lack of artistic control and by his repellent fascination with cruelty and violence. *Lenten stuffe*, purportedly a panegyric of red herrings, contained a charming description of Yarmouth, Norfolk, and a serio-comic treatment of Hero and Leander.

By his share in a lost stage comedy entitled *The Isle of Dogs* (1597) and labeled seditious, Nashe offended the authorities. Exactly what punishment he received is unknown, but Ben Jonson and others were temporarily imprisoned. In the remaining years of his life Nashe apparently retired from London to Yarmouth. He died in 1600 or 1601. Nashe was the first of the English prose eccentrics, an extraordinary inventer of verbal hybrids, and, according to C. S. Lewis, "the supreme master of literary *sansculottisme*." (C. S. Lewis, *English Literature in the Sixteenth Century*, Oxford University Press, London, 1954.) Unfortunately he neither had time because of financial need nor the temperament necessary to realize fully his undoubted talents.

The Works were edited by R. B. McKerrow, five volumes (1904–10; revised edition by F. P. Wilson, 1958).

Bibliography.—C. S. Lewis, *English Literature in the Sixteenth Century* (1954); D. J. McGinn, "Nashe's Share in the Marprelate Controversy," *Publications of the Modern Language Association of America*, lix (1944); and E. H. Miller, "The Relationship of Robert Greene and Thomas Nashe, 1588–1592," in *Philological Quarterly* (1954). (E. H. Mr.)

NASHUA, a city of New Hampshire, U.S., is located on the Merrimack and Nashua rivers 40 mi. N.W. of Boston, Mass.; the seat of Hillsboro county. It has extensive manufacturing. With the post-World War II withdrawal of textiles the city developed a diversified industrial base through the Nashua-New Hampshire foundation, which includes shoes, paper products, electronics, chemicals, office equipment, millwork, plastics, greeting cards, asbestos products and machinery for the manufacture of plastic and paper.

The site was originally part of Massachusetts province but the 1741 boundary settlement placed it in New Hampshire. This led to local resentment and a five-year delay in applying for a charter as Dunstable, N.H. In 1803 the village of Indian Head, across the Nashua river, took the name of Nashua (believed to have been derived from a local Indian tribe). The two settlements joined in 1837 as Nashua. The northern section withdrew, as Nashville, in 1842 over a dispute in locating the town hall. They were reunited under a city charter in 1853.

Nashua is the site of Rivier, a Roman Catholic college for women, founded in 1933. The city early attracted Irish immigrants to the textile mills, followed by large numbers of French Canadians. The latter still form the major ethnic group, although Lithuanian, Polish and Greek immigrants subsequently contributed to the cosmopolitan character of the community. For comparative population figures *see* table in New Hampshire: *Population*. (L. F. R.)

NASHVILLE, capital city of Tennessee, U.S., and seat of Davidson county, is situated on the Cumberland river in the north central portion of the middle Tennessee basin. Pop. (1960) 170,874. (For comparative population figures *see* table in Tennessee: *Population*.)

History.—The first English settlement in Tennessee west of the Allegheny mountains, the city was founded in 1779 by settlers from eastern Tennessee under the leadership of James Robertson and John Donelson. The site of the city had been occupied much earlier by French traders, who operated a trading post near the present downtown area, and before that by the Shawnee Indians. It was originally named Fort Nashborough, for Gen. Francis Nash of North Carolina, and in 1784 took its present name.

One of the prime movers behind the settlement of Fort Nashborough was Richard Henderson, a North Carolina jurist, who in 1775 acquired most of middle Tennessee and Kentucky in the famous Transylvania purchase from the Cherokee Indians. He also is credited with having written the Cumberland Compact, the articles of self-government adopted by the settlers, which contained the first known provision in the United States for recall of elected officials (*see* Tennessee: *History*). Henderson's settlement was under frequent Indian attack in its early years and for a while these attacks seemed likely to destroy the infant colony. But with the end of the American Revolution many new settlers arrived increasing the population and treaties of peace were soon signed with the formerly hostile Indians.

The city grew rapidly in the first half of the 19th century and soon became a thriving trade centre for the entire middle Tennessee area. Radiating from the city like the spokes of a wheel was an extensive system of turnpikes over which the produce of the surrounding area was brought to the city's Cumberland river docks. Nashville's commercial importance was further enhanced in the 1850s when it acquired railroad connections with major commercial cities to the north and south. The city also became a political centre of the state. In 1826, just two years before Andrew Jackson became president of the United States, Nashville was selected as temporary capital of the state; in 1843 it became the permanent capital.

Its transportation facilities and strategic location made Nashville an important city in the campaigns of the American Civil War. It was occupied by Federal troops in Feb. 1862, shortly after the capture of Ft. Donelson, the Confederacy's key defense position on the Cumberland river. Nashville was under Federal

military control for the remainder of the war and from March 3, 1862, to March 1865 it was the seat of government for Military Governor Andrew Johnson. It also was a major supply base for Federal operations in the lower South. Its warehouses and railroads played an important part in Gen. William T. Sherman's 1864 campaign against Atlanta.

The last major battle of the Civil War took place at Nashville a few months after the fall of Atlanta. Confederate Gen. John B. Hood moved back into Tennessee in an effort to cut Sherman's supply lines and perhaps threaten Cincinnati and other northern cities. After suffering heavy losses in the battle of Franklin (Nov. 30, 1864), Hood advanced to the southern outskirts of Nashville, about 15 mi. N. of Franklin and there established defensive lines across the railroad tracks leading south. On Dec. 15, 1864, the Union army, commanded by Gen. George H. Thomas, marched out against Hood and overwhelmingly defeated the badly outnumbered Confederates. On the following day the Union victory was made complete and the Confederate army retreated in near disorder into Alabama.

Since Nashville had been occupied early in the war and without a fight, the city suffered less physical destruction than most occupied southern cities. Union warehousing and supply operations were not without economic benefit to the city and the many Federal soldiers who remained in Nashville after the war helped promote its economic recovery. Nashville resumed and improved its position as a leading investment and commercial centre and by the turn of the century was also becoming an important manufacturing centre in the state. Its continuing industrial development was greatly accelerated in the 20th century by the availability of cheap electric power from the Tennessee Valley authority and from the Cumberland river dams of the U.S. army corps of engineers.

Population and Government.—In 1960 the Nashville standard metropolitan statistical area (SMSA), consisting of Davidson county, had a population of 399,743. In 1963 the SMSA was enlarged to include Sumner and Wilson counties, bringing its population (based on the 1960 census) to 463,628.

Prior to April 1, 1963, government of the city was by a mayor and council, while most residents of Davidson county outside the city were governed by a county judge and county court. A few areas in the suburbs were incorporated as separate cities under varying forms of city government. For many years the city had been slow to expand its boundaries. On June 29, 1962, however, a new metropolitan form of government, to replace the separate city and county governments, was adopted in a special election. The validity of this new form of government was subsequently affirmed by the state supreme court on Oct. 5, 1962, and put into effect on April 1, 1963. During the following year a planned and orderly consolidation of city and county functions was effected. While these changes were being made, the city was also engaged in ambitious and progressive programs of urban renewal, slum clearance, improved street lighting, expansion of airport facilities and other civic improvements.

As was the case with other Tennessee cities, Nashville was for many years grossly underrepresented in the state legislature. The U.S. supreme court decided in *Baker* v. *Carr* (1962) that the state's legislative apportionment was a proper subject for review by federal courts, resulting in legislation giving greater representation to Nashville and other urban areas (*see* TENNESSEE: *Government*).

Commerce, Industry and Transportation.—Nashville has a well diversified economy. Investment firms and insurance firms are both important. There are more than 500 manufacturing plants but no single one is a dominant element in the city's economy. The largest industrial plant is one producing dacron and cellophane at Old Hickory, a suburban industrial city built as an explosives centre during World War I. Other major industries produce shoes, major parts for airplanes, vacuum bottles and lunch kits, river transport equipment and paper bags. Important additions to the city's industrial development include a glass plant and a rubber plant.

Nashville is widely known as a religious centre. It is the site of the national headquarters of several boards and agencies of the Methodist Church, the Sunday School board of the Southern Baptist convention and the international headquarters of the Disciples of Christ Historical society. The Methodist Publishing House is said to be the largest religious publishing house in the world and is one of the few major publishers that operates its own printing plant; its interdenominational magazine *The Upper Room* is claimed to be the world's most widely used devotional guide, being printed in over 30 languages. This publishing house is only one of a large number that make printing and publishing one of the city's major industries. The Southern Baptist convention also operates a publishing house.

During the second quarter of the 20th century the city became widely known as an entertainment centre, largely through its "country music" industry. Regular radio broadcasts of the "Grand Ole Opry" began in 1925 and national network broadcasts in 1939; it consistently attracted capacity audiences to its performances in historic Ryman auditorium. Country music is also the mainstay of a very large recording industry.

Nashville is served by several airlines, two railroads and more than 40 motor-freight lines, several of which have their home offices in the city. It is the major river port on the Cumberland.

Education.—Vanderbilt, a private university founded in 1873, ranks as one of the nation's leading universities; it has schools of liberal arts, medicine, law, religion, engineering, nursing and graduate studies. On adjoining campuses are George Peabody College for Teachers (private), founded as Davidson academy in 1785, and Scarritt College for Christian Workers, a Methodist senior college and graduate school chartered in 1924. Nearby is Belmont college, established in 1951 by the Tennessee Baptist convention on the historic property formerly occupied by Ward-Belmont college, now defunct; farther south is David Lipscomb college, founded in 1891 and affiliated with the Churches of Christ. In the west portion of the city are Fisk university, established in 1865 and affiliated with the American Missionary association, and, on an adjoining campus, Meharry Medical college (Methodist), founded in 1876. Still farther west is Tennessee Agricultural and Industrial State university, established in 1912. The city also has two highly regarded private preparatory schools, Harpeth Hall (for girls) and Montgomery Bell academy (for boys). Well-known private schools in nearby outlying towns are Battle Ground academy in Franklin, Castle Heights Military academy in Lebanon and Columbia Military academy in Columbia, all for boys.

Parks and Recreation.—Nashville's park system includes more than 30 city parks. The best known is Centennial park, which occupies 132 ac. of the state centennial exposition grounds and features the world's only full-scale reproduction of the Parthenon. Edwin Warner park and Percy Warner park, adjoining each other in the southwestern portion of the county near the city's Fine Arts Center and Botanical Gardens, contain 2,665 ac. of hilly land of great natural beauty. These parks contain scenic roads, picnic and play areas, hiking and riding trails and a municipal golf course. Old Hickory lake, a 22,500-ac. impoundment of the Cumberland river, is another major recreational area.

The area's best-known historic site is The Hermitage, the home of Andrew Jackson. It annually attracts thousands of visitors, many of whom also visit Belle Meade, a famous 19th-century plantation home and thoroughbred nursery; Traveler's Rest, the home of Jackson's close friend and business associate, John Overton; and Ft. Nashborough, a reconstruction of the fort around which the city developed. (W. T. A.)

NASI, JOSEPH (1520?–1579), Jewish statesman and financier, who rose to a position of power in Turkey under the sultans Suleiman the Magnificent and Selim II. Of Marrano descent, Nasi was born in Portugal and baptized under the Christian name of João Miguez. He moved to Antwerp in 1536 with his aunt Doña Gracia Nasi, wife of the banker Francisco Mendes. There he gained a thorough knowledge of commercial and financial affairs in the service of the house of Mendes. In 1554 Nasi settled at Istanbul, declared himself to be a Jew and married his cousin Reyna, the daughter of Doña Gracia. He soon attained high favour with Sultan Suleiman and his son Selim. At Tiberias in Palestine—the town and seven neighbouring villages were granted to him by the sultan in 1561—he strove to establish a community

of Jewish refugees from Europe. Five years later, in 1566, Selim II, having just ascended the Ottoman throne, made him duke of Naxos. His influence, hostile to Venice, contributed not a little to the decision made at the Porte in 1571 to attempt the conquest of Cyprus. After the death of Selim II in 1574 Nasi found himself excluded from an effective role in public affairs. The last years of his life were spent in virtual retirement at his villa of Belvedere near Galata. He died there on Aug. 2, 1579.

See C. Roth, *The House of Nasi, the Duke of Naxos* (1948).

(V. J. P.)

NASIK, a town and district in the Bombay division of Maharashtra, India. The town, headquarters of the district, lies on the Godavari river, 6 mi. from the Central railway and 110 mi. N.E. of Bombay. Pop. (1961) 131,103. It is a place of Hindu pilgrimage because of the sanctity of the Godavari river and the belief that Rama, the legendary hero of the epic *Ramayana,* lived there for a time with his wife Sita and his brother Lakshman. The town lies mainly on the right (south) bank of the river; Panchavati, the quarter on the left bank, has several temples. The river banks are lined with ghats (stepped bathing places). The town has an arts and science college, affiliated to Poona university, and is the seat of an Anglican bishop. Brass- and copperware, especially statues, caskets, chains and lamps, are manufactured. Interesting places include the *Dasahara* maidan (open space), the Jain Chambhar caves and Pandu Lena, a group of Buddhist caves (1st century B.C.–6th century A.D.).

NASIK DISTRICT, with the exception of a few villages in the west, is on a plateau 1,300–2,000 ft. above sea level. Area 6,020 sq.mi. Pop. (1961) 1,855,246. The west is hilly and intersected by ravines; the east is open, fertile and well cultivated. The Sahyadri range stretches north-south, the watershed formed by the Chandor range running east-west. All streams south of this watershed join the eastward-flowing Godavari; north of it the Girna and its tributary the Mosam join the westward-flowing Tapti. The Kadva canal (1874), the Girna left-bank canal (1909) and the Godavari right- and left-bank canals (1911) irrigate about 87,000 ac. At Gangapur, 8 mi. W. of Nasik, an earthen dam (built 1949–54) irrigates about 45,000 ac. The chief crops are bajra, jowar, pulses, oilseeds, cotton, sugarcane, guavas, potatoes, peanuts and betel nuts. Manufactures include cotton and silk textiles, gold and silver thread and copper, brass and silver vessels. At Ravalgaon is a sugar factory and there are railway workshops at Igatpuri and Manmad. Places of interest include the Govindeshwar temple at Sinnar, the Ankai and Tringalwadi caves near Igatpuri, the Jogeshwar temple in Baglan, and numerous hill forts. Other larger towns include Malegaon, Yeola and the military station Deolali. (M. R. P.)

NASIR AD-DIN (NASR AD-DIN) (1831–1896), shah of Persia from 1848 to 1896, was born probably at Teheran on July 17, 1831. Although not the eldest son of his father, Mohammed Shah, he was, through his mother's influence, made heir apparent. Serious disturbances which broke out on his accession in 1848 were quelled mainly through the efforts of his extremely capable and honest chief minister, Mirza Taqi Khan. Thereafter some much-needed reforms were introduced. These reforms, however, made Taqi Khan many enemies, and he was hated by the queen-mother, who had great influence over the young shah. The consequence was that Taqi Khan was disgraced and finally murdered. In 1853 the shah himself narrowly escaped death at the hands of three fanatical Babis (*see* BABISM). Although in general kindly and humane, Nasir ad-Din thereupon embarked on a fierce persecution of the Babis.

Being unable to regain any of the territory lost to Russia in the two disastrous wars which were waged in the reign of Fath Ali Shah, Nasir ad-Din endeavoured to seek some compensation for these losses by seizing Herat in 1856. Great Britain thereupon declared war on Persia, forcing the shah to relinquish Herat and to recognize the kingdom of Afghanistan.

Although imbued at first with liberal ideas through the influence of Taqi Khan, the shah subsequently became opposed to reforms. Nevertheless, he ruled his country firmly and well for the greater part of his reign. It can indeed be said that he was the best sovereign of the Qajar line. He curbed the excessive power of the mullahs by the gradual reassertion of the civil authority and by the introduction of the lay administration of religious properties; and despite his fear of reforms, he took certain measures which resulted in the partial opening up and modernization of the country. Telegraph and postal services were introduced; the construction of roads practicable for wheeled traffic was begun; and education on modern lines was initiated by the establishment, in 1851, of the *Dar al-Funun* (École Polytechnique) in Teheran, where modern scientific ideas and European languages could be studied.

Nasir ad-Din visited Europe in 1873, 1878 and 1889; he kept diaries of these visits which were published in Persian and English. The shah became unpopular in his later years because of his refusal to yield to the increasing demands for reforms and of his granting extensive concessionary rights to foreigners in return for lavish payments most of which went into his own pocket. He was assassinated at Teheran by a fanatic on May 1, 1896. *See* also IRAN: *Administration and Social Conditions;* PERSIAN HISTORY: *Qajar Dynasty.*

See G. N. Curzon, *Persia and the Persian Question,* vol. i, pp. 391–412 (1892); J. Feuvrier, *Trois Ans à la cour de Perse,* 2nd ed. (1906).

(L. Lo.)

NASIR-I KHUSRAU (1004–1088), Persian poet, theologian and religious propagandist, whose later life and work were influenced by his conversion to Isma'ilism, was born near Balkh (in Afghan Turkestan) of a Shi'ite family. He served in the Saljuq government of Khorasan before resigning to make the pilgrimage to Mecca. Continuing his journey into Palestine and Egypt, he was impressed by the splendour of Fatimid rule in Cairo and it was as an ardent Isma'ili convert that he returned to Balkh in 1053. His vigorous advocacy of that heresy obliged him soon to flee to the mountains of Badakhshan (northwest Hindu Kush), where he ended his days. His poems of a didactic and devotional character consist mainly of long odes considered to be of high literary quality; he is also credited with two moralizing sequences, the *Sa'adat-nama* and the *Raushana'i-nama.* His most celebrated prose work is the *Safar-nama,* a diary describing his journey. It is a most valuable record of the scenes and events which he witnessed. He also wrote more than a dozen treatises expounding the doctrines of the Isma'ilis, among them the *Jami' al-hikmatain,* in which he attempted a harmony between theology and philosophy. Nasir-i Khusrau's style is straightforward and vigorous. In his verse he displays great technical virtuosity, while his prose is remarkable for the richness of its philosophical vocabulary.

Wickens, two articles in the *Islamic Quarterly,* vol. ii, pp. 117–132, 206–221 (1955) and vol. iv, pp. 66–67 (1957) on the "Sa'adat-nama" and "Safar-nama" respectively. (A. J. AY.)

NASIRIYAH (AN NASIRIYAH), a town of southern Iraq, capital of the *liwa'* (province) of the same name, about 110 mi. N.W. of Basra. Pop. (1957) 39,060. A bridging point and local market situated on the north bank of the Euphrates, Nasiriyah was founded about 1870 by Nasir Sadun Pasha, then paramount sheikh of the Muntafiq confederation, who became an Ottoman official and furthered Midhat Pasha's policy of reducing nomadism in Iraq. The town, surrounded by a mud wall and numerous bunds to prevent flooding, is built mainly of brick (mostly sun-dried), with relatively broad streets. About three-quarters of the population are Shi'ah Muslims, and there is a community of Sabians engaged in silverworking, boatbuilding and carpentry, together with a few Persians and Kurds.

NASIRIYAH LIWA', formerly named after the Muntafiq tribe, lies between Diwaniyah *liwa'* on the west and Basra *liwa'* on the east. Area 5,580 sq.mi. Pop. (1957) 455,644. Though relatively small in size, it is one of the most densely populated regions in Iraq owing to the relative abundance of cultivated land and the presence of many nomads and semisettled pastoralists. Wheat, barley and dates are grown, and there is an important rice area in the extreme southeast extending from the head of Lake Hammar. The sheep-herding nomads play a greater part in local economic life than they do in many other riverine areas of Iraq. Corresponding

closely in boundaries with the Ottoman sanjak of Muntafiq, which with Basra and Amarah formed the old *vilayet* of Basra, Nasiriyah *liwa'* is the lowest portion of the Euphrates valley before the river spreads out into the extremely shallow and marshy Lake Hammar. The ruins of Larsa, Ur, Erech, Eridu and Lagash are all found in this region. (W. B. Fr.)

NASMYTH, ALEXANDER (1758–1840), Scottish portrait and landscape painter, was born in Edinburgh on Sept. 9, 1758. His work attracted the attention of the portrait painter Allan Ramsay, who took him to London and employed him upon the subordinate portions of his portraits. Nasmyth returned to Edinburgh in 1778, and was soon largely patronized as a portrait painter. He also assisted Patrick Miller of Dalswinton, as draftsman, in his mechanical researches and experiments. Miller advanced him money to go to Italy in 1782, where he remained two years. On his return he painted the portrait of Robert Burns now in the Scottish National Portrait gallery. Although they are little known, some of his portraits, and in particular the conversation pieces he executed in the 1780s and 1790s, are of considerable interest. Nasmyth's pronounced Liberal opinions gave offense to many of his aristocratic patrons, and led to the diminution of his practice as a portraitist. In his later years, accordingly, he worked mainly at landscapes. His subjects are carefully finished and coloured, but are wanting in boldness and freedom. He also designed sets for the theatre and worked as an architect. He invented the "bow-and-string" bridge and is known for his designs for the Dean bridge, Edinburgh, and the graceful circular temple covering St. Bernard's well. Nasmyth died in Edinburgh on April 10, 1840.

NASMYTH, JAMES (1808–1890), Scottish engineer and inventor of the steam hammer, was born in Edinburgh on Aug. 19, 1808, the youngest son of Alexander Nasmyth (*q.v.*). He started his own business in Manchester in 1834, and in a few years was at the head of the prosperous Bridgewater foundry at Patricroft, near Manchester. The invention of the steam hammer was actually made in 1839, when a drawing of the device appeared in his notebook, or "scheme-book," as he called it, in that year. Nasmyth designed the steam hammer to meet the difficulty experienced by the builders of the "Great Britain" steamship in finding a firm that would undertake to forge the 30-in.-diameter paddle wheel shaft originally designed for that vessel, but he did not construct the machine until 1843. He did much to improve machine tools and devised many new appliances—the shaping machine ("Nasmyth steam-arm"), a nut-milling machine, steam pile driver, and hydraulic machinery. He died in London on May 7, 1890.

His autobiography was edited by Samuel Smiles (1883).

NASRIDS, the last of the Muslim dynasties of Spain, ruled in Granada from 1238 to 1492 (*see* Granada, Kingdom of). The family rose to power in the turmoil which followed the defeat of the Almohads at the battle of Las Navas de Tolosa in 1212. The first Nasrid ruler, Mohammed I (d. 1273), became a tributary vassal of King Ferdinand III of Castile and assisted him at the capture of Seville in 1248. He started the construction of the Alhambra (*q.v.*) and laid the basis of Granada's prosperity by welcoming refugees from Seville, Valencia and Murcia. His successors were weakened by dynastic and factional strife: in two and a half centuries there were 20 Nasrid rulers. Most of them died violently; several were expelled and restored two or three times. The dynasty wavered between submission to Castile and dependence on their Marinid kinsmen of Fès, whose mercenaries often dictated the political fortunes of Granada. The African alliance proved disastrous, leading, for example, to the defeat of Yusuf I (1333–54) at Río Salado (1340) by Alfonso XI. After two centuries of internal disorder and border warfare, in which the Christians had taken a series of key positions (notably Gibraltar in 1462), Nasrid rule was finally doomed by Mulay Hasan (Abu-l-Hasan Ali) (1466–82), who renewed hostilities against Castile and at the same time plunged his subjects into civil war by opposing the succession of his legitimate heir, Boabdil (*q.v.*).

NASSAU, the capital of the Bahamas, is a port on the northeastern coast of New Providence Island. Founded on the site of the village of Charles Towne, it was not until 1690 that it took its present name and not until 1729 that the city was laid out. (*See also* Bahamas.) Pop. (1963) 80,907.

The temperate climate (average temperature November–May, 23° C. [74° F.], June–October, 28° C. [82° F.]), beautiful scenery and fine beaches make Nassau one of the chief pleasure resorts of the world. The city proper covers a comparatively small area but the residential districts extend for a considerable distance along the coast. From Bennett's hill, a ridge south of the city, there is a view not only of the city and harbour but also of almost the whole island. The water tower, a conspicuous landmark on the ridge, is the source of the city's water supply. Below the tower is Ft. Fincastle (1793), one of several built during the 18th century when Nassau was fortified. On Mt. Fitzwilliam above the city is the imposing white building of Government house; in the middle of a long flight of steps in front of it stands a statue of Christopher Columbus. On George street, which leads downhill to the town, stands Christ Church Anglican cathedral. The city's centre is Rawson square with the law courts and chief government buildings; Christ Church cathedral and the public library are nearby. The main shopping and business street is Bay street, which also has the public market (1901). Bay street runs parallel with the harbour front. Offshore, at the eastern end of the harbour, are the marine gardens, where glass-bottomed boats are available for sight-seeing. The natural vegetation of Nassau is exceedingly beautiful, the scarlet poinciana tree flowering from May to September and the poinsettia at Christmastime, and the purple bougainvillea growing profusely along the hedgerows. In the Ardastra gardens along Bay street to the west of the city are many rare tropical plants.

The harbour, which is sheltered by Hog Island, accommodates vessels of 24-ft. draft. There are no important industries on the island, but products including sisal, sponges, citrus fruits, tomatoes and pineapples are exported.

Nassau is easily reached by sea or air. From the airport at Windsor field there is regular service to airports in the U.S., Great Britain and elsewhere. There is also local service to other islands in the Bahamas.

See W. W. Cartwright (ed.), *Pocket Guide to Nassau,* 8th ed. (1954); *Historic Forts of Nassau* (1932).

NASSAU, a historic territory of western Germany, corresponding under the Federal Republic of Germany to the westernmost part of the *Land* Hesse (*q.v.*) together with the district of Montabaur in the *Land* Rhineland-Palatinate. In its consolidated form (1816–66) as a sovereign duchy, Nassau had an area of 1,830 sq.mi., being divided approximately into halves by the Lahn river and bounded south by the Main, southwest by the Rhine, northwest and north by parts of Prussia's Rhine province and Prussian Westphalia and east by parts of Grand-Ducal Hesse, by Prussian Wetzlar, by Hesse-Homburg and by Frankfurt am Main. South of the Lahn are the Taunus mountains; north is the barren Westerwald. Thickly wooded, Nassau has valleys rich in grain and fruit, notable vineyards, numerous spas and deposits of iron, lead, copper, silver and malachite.

History.—In Roman times the south of the country was inhabited by the Germanic Mattiaci. During the great migrations, it was occupied by the Alamanni. The Franks, having annexed the north, overran the south in the reign of Clovis; and in the 6th–7th centuries Christianity was introduced. Before 1128 the counts of Laurenburg, of the local nobility, built a castle overlooking the Lahn near the town of Nassau; and Walram (d. 1198) took the title of count of Nassau. His grandsons divided their inheritance in 1255: Walram II took the south, with Weilburg, Idstein and Wiesbaden; Otto I took the north, with Dillenburg and Siegen.

Walramian Nassau.—Walram II's son Adolf (*q.v.*) was German king from 1292 to 1298. His descendants, however, continually partitioned their lands. Nassau-Weilburg, separated from Nassau-Idstein-Wiesbaden in 1355, became a princely countship of the *Reich* in 1366 and acquired Saarbrücken and also Commercy (in Lorraine) in 1381, but was split into Weilburg and Saarbrücken branches from 1442 to 1574 and again in 1574 and 1594. After the reversion of the whole Walramian inheritance to Weilburg (1605) new partitions in 1629 and 1651 divided it between three lines,

Weilburg, Idstein and Saarbrücken-Usingen. The last named was subdivided into branches of its own from 1659 to 1728 and from 1735 to 1797, but had the Idstein succession from 1722.

When the lands west of the Rhine were ceded to France (1801), Nassau-Weilburg and Nassau-Usingen made common cause and won substantial compensation in 1803 (*see* GERMANY: *History*). Entering Napoleon's Confederation of the Rhine and making some cessions to Berg in 1806, Walramian Nassau received further territory (notably at the expense of Ottonian Nassau) and became a duchy. It was maintained as a sovereign duchy by the congress of Vienna; and the extinction of the Usingen line in 1816 made William of Weilburg (1792–1839) sole duke of Nassau. His successor Adolf (1817–1905) took Austria's side in the Seven Weeks' War; and on Oct. 3, 1866, Nassau was annexed by Prussia—to form the bulk of the Wiesbaden district of the province of Hesse-Nassau.

Ottonian Nassau.—Otto I's descendants also indulged in partitions and subdivisions: Dillenburg and Hadamar (1290–1394); Dillenburg-Dillenburg and Dillenburg-Beilstein (1343–1561); and Dillenburg-Dillenburg and Dillenburg-Breda (1516–44). It was by legacy from the Breda branch that William of Nassau-Dillenburg became prince of Orange (*see* ORANGE, HOUSE OF; WILLIAM I the Silent). The sons of his brother John VI of Nassau-Dillenburg (d. 1606) effected a fourfold partition of their patrimony, but the branch of Nassau-Dietz eventually reaccumulated it as the others died out (Nassau-Hadamar in 1711, Nassau-Dillenburg in 1739, Nassau-Siegen in 1743). Having lost their German possessions in 1806, the Ottonians in 1815 received Luxembourg in compensation. They also had the kingdom of the Netherlands. When their male line died out in 1890, Luxembourg passed to their distant Walramian cousin Adolf.

NASSER, GAMAL ABD-AL- (1918–), Egyptian army officer and political leader, became the president of Egypt in 1956. He was born at Beni Mor in Asyut province, upper Egypt, on Jan. 15, 1918, the son of a post-office civil servant, and was educated in Cairo at a secondary school and at the military college to which, after a period of normal military duties, he was appointed a lecturer in 1942. Intensely patriotic and politically active, Nasser formed a group of young officers dedicated to the cause of Egyptian nationalism. By 1945 a substantial group of "free officers" formed a secret organization around Nasser. The Palestine war of 1948–49, in which Nasser narrowly escaped death from a chest wound, did much to harden their bitterness and determination. After the war the organization of the free officers was tightened, and underground propaganda against the regime was undertaken. In July 1952 the coup was executed that led to the deposition of King Faruk (*q.v.*). Although from the outset real power rested in the hands of the Revolutionary Command Council of 11 officers controlled by Nasser (by this time a lieutenant colonel), Maj. Gen. Mohammed Naguib (*q.v.*) was at first put forward as the leader of the military regime. In 1953 Naguib was named prime minister and president of the new republic with Nasser as deputy prime minister and minister of the interior. In 1954, however, Naguib was deprived of his titles, and Nasser, escaping unhurt from an attempt on his life in Alexandria, emerged as prime minister and the real ruler of Egypt. In June 1956 he was elected president.

Nasser, like most of the other cadets who joined the military college with him in 1936, had sprung from the *fellah* middle class, the native Egyptians of the provincial towns. What he and they wanted was not only the effective independence of the country but good, uncorrupt government in the hands of people like themselves. Something of their aims at this time may be learned from Nasser's published writings and speeches (including his *Philosophy of the Revolution*, 1954).

Although at first inexperienced in the problems of power, Nasser soon became not only a national but an international figure. His first major success was the negotiation of the agreement for the withdrawal of British troops from the Suez canal zone (1954). His

nationalization of the Suez Canal Company (July 26, 1956), following withdrawal of Western promises of aid in building the Aswan High Dam, was interrupted, but only briefly, by the Suez conflict of that year (*see* SUEZ CANAL), from which Nasser emerged with great prestige throughout the Arab world. One consequence of this prestige was the Syrian-Egyptian union of February 1958 which led to the creation of the first United Arab Republic (U.A.R.), of which Nasser was the president. This federation to which Yemen had become affiliated, collapsed in 1961 with Syria's secession, but following military coups in Iraq (February 1963) and in Syria (March 1963) a draft constitution, subject to referendum, for a second (tripartite) U.A.R. federation was signed in Cairo on April 17, 1963 (*see* UNITED ARAB REPUBLIC). Nasser's aspirations toward leadership of the Arab world were strongly based on the resources, political stability, and social and economic progress of Egypt. Among Arabs, he became the principal symbol of modernization without loss of identity, and of government in the interests of the people. His leadership was repeatedly challenged —by the Syrian Baath Party, by the rulers of Saudi Arabia and Jordan from time to time, and in 1964 by Pres. Habib Bourguiba of Tunisia—but it remained strong.

Other main features of Nasser's regime have been his hostility toward Israel (*q.v.*); anticolonialism; support for the nonaligned nations; occasional moves toward leadership among the emerging African nations; and the use of Cairo radio for the dissemination of political propaganda. In the Yemeni civil war which broke out in 1962, he gave strong military support to the Republican Party.

In Egypt he remained strong and provided government which inspired more continuing confidence than could be felt in most major developing countries. The problems were very great, not the least being a sharply rising population, but the standard of living improved perceptibly though slowly. Opposition, not easily expressed, showed itself principally through the Muslim Brotherhood, which was twice severely repressed. The Aswan Dam, the first stage of which was completed in 1964, was important not only economically but as a symbol of what Egypt under Nasser was trying to achieve and as some indication that these purposes were consistently pursued and capable of a large measure of fulfillment. *See* also EGYPT: *History*.

NAST, THOMAS (1840–1902), U.S. cartoonist, best known for his attack on the political machine of William M. Tweed (*q.v.*) in New York city in the 1870s, was born in Landau, Ger., on Sept. 27, 1840. He was brought to New York city by his mother in 1846. He studied art there with Theodore Kaufmann and at the National Academy of Design, at the age of 15 became a draftsman for *Frank Leslie's Illustrated Newspaper,* at 19 for *Harper's Weekly,* at 20 went to England for the *New York Illustrated News* and in the same year went to Italy to cover Garibaldi for *The Illustrated London News* and U.S. publications. His cartoon, "After the Battle" (1862), attacked Northerners opposed to pushing the Civil War vigorously. This and other cartoons published in *Harper's Weekly* during the Civil War led President Lincoln to call him "our best recruiting sergeant." Nast's cartoon campaign against Tweed was climaxed when a caricature of him led to his identification and arrest in Vigo, Spain, in 1876. Originally a Republican, Nast turned first to the Mugwumps because of his advocacy of civil service reform and his distrust of James G. Blaine and in 1884 to the Democrats; in 1892 he returned to the Republicans. Having lost nearly all his money in the failure of the brokerage house of Grant and Ward in 1884, he was appointed consul general at Guayaquil, Ecuador, by Pres. Theodore

Roosevelt in 1902, and he died there on Dec. 7 of the same year.

Nast did some painting in oil and book illustrations, but his fame rests on his caricatures and political cartoons. From his pen came the Democratic party's donkey, the Republican party's elephant, and Tammany Hall's tiger.

(D. H. W.)

NASTURTIUM, the common name for soft-stemmed flowering plants of the genus *Tropaeolum,* only a few of the 50 species constituting the family Tropaeolaceae being cultivated as ornamentals, and the generic name sometimes used for certain aquatic crucifers (*see* WATER CRESS).

The garden nasturtium or Indian cress (*T. majus*), like others of the genus, is native to South America; it is a perennial climber in Peru, but in cultivation is treated as a hardy annual. It climbs by means of the long stalk of the peltate leaf which is sensitive to contact like a tendril. The irregular flowers have five sepals united at the base, the dorsal one produced into a spur; of the five petals the two upper are slightly different and stand rather apart from the lower three; the eight stamens are unequal and the pistil consists of three carpels which form a fleshy fruit. The pungent leaves are sometimes eaten in salads, and the young green fruits are pickled in vinegar as a substitute for capers. The dwarf variety known as Tom Thumb (*T. m. nanum*), is an excellent bedding or border flower, growing about one foot high. Other fine annual tropaeolums are *T. peltophorum,* with long spurred orange-red flowers, and *T. minus,* a kind of miniature *T. majus* with yellow, scarlet and crimson varieties. *T. peregrinum* is the well-known canarybird flower. A fine nasturtium with brilliant scarlet blossoms is *T. speciosum* from Chile; it has tuberous roots, as have also such perennials as *T. polyphyllum* and *T. pentaphyllum. T. tuberosum,* the anu, is grown in the Andean highlands for its edible tubers.

J. HORACE MCFARLAND CO.

NASTURTIUM (TROPAEOLUM MAJUS)

Garden nasturtiums are easily grown from seed, which is sown in a warm, sunny location after the danger of frost is past. They are quick growing and, if planted in too rich soil, may produce an abundance of foliage at the expense of blossoms. Cuttings made in autumn provide potted plants for winter blooms indoors.

See also TROPAEOLACEAE.

NATAL, the smallest of the four provinces of the Republic of South Africa, has an area of 33,578 sq.mi., or 7.11% of the area of the Republic. This area includes Zululand and Tongaland (*qq.v.*), which lie between the Tugela river and the Portuguese East African (Mozambique) border, together occupying 10,362 sq.mi. The province is bounded on the west by the Drakensberg escarpment, on the south partly by the upper Umzimkulu river and the Mtamvuna river. The northern boundary lies for most of its distance along the Pongola river, along the crest of the Lebombo range as far north as Usutu *poort,* along the Usutu river to its confluence with the Ingwavuma and from there to the 13th beacon along the boundary line with Portuguese East Africa, on the coast, 5 mi. N. of the inlet to Kosi bay. The provincial capital is Pietermaritzburg.

PHYSICAL GEOGRAPHY

Landforms.—The province lies in the eastern marginal area of the Republic of South Africa. Most of its surface is formed of beds belonging to the four series of the Karroo system, which in the coastal region have been folded to form the Natal monocline. Pre-Karroo formations (Archean granite, Table Mountain Sandstone, etc.) have been exposed along most of the monoclinal axis, except in a small area to the north of the Tugela river where the Karroo beds are still intact. In the lower Tugela basin the axis has been dislocated by a number of east-trending faults. In Zululand the flat coastal plain is covered by marine Tertiary beds forming the southern extremity of the great Mozambique plain.

Steeply graded rivers have worked powerfully on the different rocks to produce the present surface features, and headwater erosion of the largest of these rivers into the Stormberg basaltic lavas has carved out the prominent Drakensberg mountains (*q.v.*). Such deep river erosion has left high interfluvial spurs trending eastward from the plateau edge. Where strong sheets of dolerite have resisted erosion, wide open basins have been formed in the interior above such rock barriers. Two of these basins which occupy a considerable area are the Ladysmith basin on the upper Tugela river and the Newcastle-Utrecht basin on the upper Buffalo river. In general three surface divisions can be recognized: a coastal zone rising to between about 1,500 and 2,000 ft.; a midland zone on the interfluvial spurs rising to about 3,500–4,000 ft., and a high veld area from about 4,000 ft. up to the foot of the Drakensberg escarpment.

Climate.—Atmospheric temperature is related closely to altitude. Mean temperatures in July are highest in the coastal belt, where they exceed 15° C. (60° F.), and lowest on the high veld, where they are between 7° and 10° C. (45° and 50° F.). In January the mean monthly temperatures of the coastal belt to the north of Durban exceed 24° C. (75° F.), and in the interior basins and in Zululand the mean maximums generally exceed 29° C. (85° F.). Temperatures often exceed 32° C. (90° F.) when berg winds blow from the plateau. Frost is rare in the coastal belt except in July, when light frosts may occur in valley bottoms. In the high veld area the duration of the frost period extends from about the middle of May to the middle of September.

Natal lies wholly in the region of predominantly summer rainfall, but the coastal belt receives in general rather more than 30% of its annual rainfall in the winter half-year. From the coast to the midlands the mean annual rainfall decreases from about 40 in. to about 30 in., but increases with altitude to about 40 in. in the high veld areas. On the Drakensberg the precipitation is estimated to be over 60 in. The reliability of the annual rainfall over the province as a whole is between 80% and 90%. An important feature of the midland zone is the frequency of mist so that certain parts of the zone are known as the mist belt and are well suited to afforestation, especially of wattles.

Vegetation.—The coastal belt of subtropical forest or dense evergreen bush extends for 6 to 20 mi. from the coast. This is succeeded inland by more open bush or savanna which passes, in the southern part of the province, into remnant patches of temperate forest. Lying at an altitude of between about 3,000 and

BURTON HOLMES FROM EWING GALLOWAY

VALLEY OF A THOUSAND HILLS, A REMARKABLE CRUMPLED FORMATION NEAR PIETERMARITZBURG

4,000 ft., this zone marks the position of the mist belt. At higher altitudes the dominant vegetal type is tall "sour" grass. The lower valleys in the south and most of the low country in the north are areas of thornbush (*Acacia savanna*).

Animal Life.—Natal contains many distinctive southern species as well as tropical African species and may be considered as a corridor in which southern and northern fauna have intermingled. Tropical forms in the northern part of the province include the tsetse fly, which formerly infested Zululand as far south as the Umfolozi river, the tree-nesting tailor-ant (*Oecophylla smaragdina*), the tiger fish (*Hydrocyon vittatus*), the ghost frog (*Chiromantis zerampelina*), the white rhinoceros, the black rhinoceros, and of the antelopes the nyala and the suni. This tropical corridor has also been the passageway to the south of many east African birds such as the hornbills, louries and trogons, and the tropical barbets and parrots.

Most of the game is preserved in the provincial reserves. In Zululand the Hluhluwe game reserve (57,000 ac.) and the Umfolozi game reserve (72,000 ac.) have white and black rhinoceros, kudu, impala, waterbuck, wildebeest, zebra, buffalo and many other animals. In the Drakensberg, the Giant's Castle game reserve contains over 1,500 head of eland besides numerous oribi, klipspringer, grysbok, reedbuck and other antelopes. In the Nkuzi game reserve in Zululand among many other antelopes are the inyala and the suni. In the extreme north of Zululand, near the confluence of the Usutu and the Ingwavuma (Ngwavuma) rivers, the Ndumu game reserve, with its freshwater pans, contains many hippopotamuses, crocodiles and numerous waterfowl, as well as the suni antelope. Along the Zululand coast are several parks and nature reserves where a great variety of birds, fish and game are protected. (J. H. Wn.)

HISTORY

In 1497 the Portuguese Vasco da Gama, on his voyage to India, sighted the bluff at the entrance to the present harbour of Durban on Christmas day and so named the country Terra Natalis. Neither then nor subsequently did the Portuguese settle or claim Natal. The nearest Portuguese settlement was 296 mi. farther north at Delagoa bay, which offered safer anchorage and a more convenient entrepôt for trade. It was, then, from shipwrecked mariners that the first tales of the Natal coast reached Portugal. King Sebastian of Portugal in 1575 commissioned Manuel de Mesquita Perestrelo to survey the South African coast and mark points for safe anchorage in storms, for these had already taken heavy toll of the merchantmen. In 1593 the wreck of the Portuguese "Santo Alberto" north of the Great Kei river left a party of 285 stranded on the shore. This group, instead of pushing north along the coast to Delagoa bay, a route already notorious for its perils, used compass and sextant to "navigate" an inland route which took them through the heart of Natal Zululand and Tongaland to Lourenço Marques. These were the first Europeans known to have penetrated to the interior of Natal.

By the 17th century English, French and Dutch challenged the Portuguese monopoly of the Indian ocean, but for Natal the story was still one of wrecks and disasters rather than of trade and settlement. In 1685 the survivors of the English slaver "Good Hope" left a small company complete with guns in a shanty fort on the bluff. The following year the Dutch trader "Stavenisse" was wrecked farther south. The survivors were joined by English from the bluff and from another English vessel, the "Bonaventura." They built a boat and sailed with a cargo of ivory to Cape Town.

In 1689 Simon van der Stel dispatched thence the "Noord" to open up trade in ivory and secure the bay of Natal. The bay was duly purchased, but the wreck of the "Noord" on the return voyage and the repudiation of the sale by the natives made the venture abortive. In 1721 another venture was made by Gov. Maurits Pasques de Chavonnes to place a settlement during the Dutch attempt to hold Delagoa bay. Both moves were abandoned in 1730. The coast was difficult and for practical purposes the hinterland of Natal was terra incognita. There was no obvious source of wealth to be tapped. For yet another century Natal was to lie off the beaten track of European adventurers. (*See* also Cape of Good Hope.)

Within Natal the Nguni branch of the Bantu seems to have settled early in the 16th century, Zulu (reputed dates 1627–1709) being but the least of many founders of tribes. A. T. Bryant in his book *Olden Times in Zululand and Natal* (1929) estimated that about 50 separate clans inhabited Natal proper at the opening of the 19th century and hazarded the calculation that at least 78,000 and probably 100,000 natives were technically aboriginals in Natal. North of the borders of modern Natal, the Tembu-Tongas seem to have acted as middlemen between the Portuguese traders and the natives in Zululand and Natal. They are credited with introducing maize (corn), yams, peanuts and, legend has it, cats into Natal. Throughout the hinterland, which of course had as yet no political boundaries, there were the petty wars about land and cattle common to all primitive societies, but no major cataclysms. The first attempt at a paramountcy was made (1807–1818) by Dingiswayo. He was chief of the Mtetwa (Umtetwa), northeast of the Tugela river. He opened up trade with Delagoa bay by exchanging oxen and tusks for blankets and beads. Until his defeat and death at the hands of Zwide, chief of the Ndwandwes (Undwandwes), in 1818 he established a rough suzerainty which Shaka (Chaka) of the Zulus was to usurp (*see* Zululand). Already before Shaka crossed the Tugela in 1818, refugee tribes from Zululand headed by the Tembus and Cunus had hacked a way through the coastal tribes of Natal. Thereafter the Zulu impis (warrior regiments) first of Shaka and then of Dingaan (Dingane) completed the dispersal and destruction which was to mislead both Boer and Briton into thinking Natal was uninhabited. Those who had not been murdered or conscripted either hid or fled. From 1821 onward all the area between the Umzimkulu and the Umzimvubu rivers was in chaos. Ncapaai of the Ama-Baxa tribe (1826–44) forged some of the exiled tribes into a massive army of about 3,000 warriors. He defied both the pressure from Natal to the north and from Pondoland to the south until his destruction by Faku, chief of the Amapondo (Pondo), in 1844. Three prime factors, then, provide clues to the policy of early European settlement in Natal: fear of Zulu military power; the myth that Natal was uninhabited; and the chaos beyond the Umzimkulu which threatened both Natal and Cape province.

First British Settlement, 1824.—One consequence of the occupation of the Cape by Britain in 1806 was the attempt to map the east coast for naval purposes. Throughout 1822 and 1823 Capt. W. F. Owen of the Royal Navy laboured at this task. Merchants and traders, already speculating in the coastal trade, followed in his track. Two former naval lieutenants, F. G. Farewell and J. S. King, arranged with Owen to finish the survey of the port of Natal and St. Lucia bay. Farewell and King failed to land at St. Lucia bay, but a renewed attempt farther south brought them triumphantly across the bar of what is now Durban harbour. The following year Farewell with H. F. Fynn and others returned to the port of Natal to found a trading station and open up negotiations with Shaka at his Bulawayo (Zululand) kraal. Chiefly because of the courage, tact and medical skill of Fynn, Shaka rewarded Farewell's party by signing a treaty (Aug. 1824) ceding the port of Natal and about 50 mi. of coastline to a depth of 100 mi. inland. This was never revoked, but Shaka seems to have regarded the traders as in some sort his vassals or subchieftains for in 1826 they were virtually conscripted into Shaka's war with the Ndwandwes. Both Shaka and Dingaan protested against shelter given to refugees from royal wrath. Shaka did not hesitate to make peremptory demands, as for instance in 1828 when he was infuriated because his ambassadors to George IV had returned empty handed from Port Elizabeth; equally because they had forgotten the Macassar oil he ordered. John Cane was compelled to set out for the Cape to purchase the oil and dared not defy. While the Cape authorities unfairly blamed the traders for the tribal upheavals, the traders themselves led a precarious existence. King died of dysentery in 1828. Farewell was murdered by Nqueto and the Kwabis in 1829 in no man's land. In 1831 Fynn and his group narrowly escaped with their lives when Dingaan raided Port Natal, and the following year Fynn withdrew to Grahamstown.

It seems clear that both Shaka and, more particularly, Dingaan and their indunas (headmen) were perturbed by European diffusion, especially after the opening of the land route through Pondoland. Jacob the interpreter, a Kaffir former convict (shot in 1832), combined distorted pictures of European power and greed with the self-claimed power to prophesy that the coming of traders and white missionaries spelled doom to the natives, and it is inconceivable that Matiwana, who was murdered by Dingaan in 1829, can have failed to report his disastrous encounter with Col. H. Somerset at Baziya Mount. In 1832 Andrew Smith arrived from the Cape to report on Natal. In 1834 a *commissie* (committee) trek arrived from the Eastern province directed by Piet Uys. They made contact with the Zulus by shouting across the Tugela and reported that Natal was vacant and available for settlement.

The European settlers at Port Natal reiterated the demand first made by King in 1826 that Natal should be taken over as a colony. In 1834 the merchants at Cape Town petitioned to the same end, while in Britain there was some mercantile support for the move. In Natal the settlers backed their demands by laying out a municipality which in 1835 they called Durban after the then governor of the Cape, Sir Benjamin D'Urban. But in the Cape the renewal of frontier war and in Britain the reluctance of the colonial office to undertake wider commitments militated against intervention. One step was essayed. Capt. A. F. Gardiner had gone to Natal as a missionary and had secured from Dingaan (May 1835) a treaty ceding the southern half of Natal, on condition that refugees were handed back to Dingaan. He also secured the appointment of the Rev. F. Owen at Dingaan's kraal at Umgungundhlovu. With this behind him he secured in 1837 magisterial authority at Durban from the Cape. But without troops or police, he had no effective control in Natal where the traders, hunters and gunrunners wanted protection without control. For this reason the traders welcomed Piet Retief, the advance envoy of the trekkers who had crossed the passes of the northern Drakensberg in the late summer of 1837.

The Voortrekkers in Natal.—The settlers welcomed Retief and guided him to Dingaan's court. Dingaan promised Retief virtually the whole of Natal provided he first recovered cattle stolen from the Zulus by Sikonyela in Basutoland. This Retief rapidly achieved by a mixture of subterfuge and force so expeditious that together with the news of the defeat of Dingaan's kinsman Mzilikazi at the Marico river (Nov. 1837) it alarmed Dingaan and the indunas. The deed of cession was duly signed and witnessed but it was sealed with Retief's blood: Piet Retief and more than 60 followers who were all unarmed being massacred on the spot (Feb. 1838). From Umgungundhlovu Zulu impis sped to exterminate the scattered laagers along the Bushmans and Blaauwkrantz rivers. Loss of life was appalling. The English from Durban hastened to the rescue with their native levies but were overwhelmed. Save for a few stalwarts the survivors embarked from Natal on the brig "Comet."

Undeterred by the murder of Retief and the death of Gert Maritz the following September, the trekkers, reinforced by timely supplies brought up by Andries Pretorius from Graaff-Reinet, simultaneously pursued two ends—the defeat of Zulu military dominance and the organization of a government in Natal in touch with trekkers west of the Drakensberg. In Dec. 1838 the Boers under the supreme command of Pretorius defeated the Zulus at the battle of the Blood river and destroyed more than 3,000 of Dingaan's army. H. Jervis, the British agent, mediated a peace in May 1839, but it was broken by both sides and Dingaan was finally defeated by the trekkers in alliance with his brother Panda (Mpande) at Magongo in Jan. 1840 and fled to his death in Swaziland. Panda made valuable concessions to the allies of his treachery. He ceded a coastal belt from the Black Umfolozi river to the entrance to St. Lucia bay, undertook to withdraw behind the Tugela and rule in the newly defined Zululand as the vassal of the new republic with its capital at Pietermaritzburg. Even before the territorial position had been secured, a constitution had been drafted. The *volksraad* (elected legislature) was to meet four times a year at the capital, leaving a *commissie raad* (town committee) to function during the long recesses. Landdrosts (magistrates) were appointed at Pietermaritzburg, Weenen and Congella and 12 field cornets were elected. Financial stringency, acute after Capt. T. C. Smith took control of the port, lack of permanent trained officials, personal quarrels between the leaders, the difficulty of keeping touch with the adjunct *raads* at Winburg and Potchefstroom, all made progress toward effective administration difficult, but not necessarily impossible. What sabotaged the structure of the republic was the influx of natives returning to Natal to resettle the lands they had abandoned to the Zulus. The attempt of the trekkers to meet the crisis by their subjection and expulsion probably decided the British to intervene.

British Annexation of Natal, 1843.—Even before the trek, various groups in Britain and in the Cape had pressed for the annexation of the port of Natal. By 1838 there were clear grounds for decisive action. There were signs of coal in Natal which made Durban, in the days of steamships, a possible coaling point; there was anxiety about French colonial projects when it was discovered that J. A. Smellekamp, self-appointed political agent who visited the new republic in 1842, was financed in Paris; there was official as well as humanitarian concern that the "apprentices" scheduled for release at the end of 1838 should in fact be released; there was the ambiguity caused by the claim of jurisdiction to latitude 25° S. in the Cape of Good Hope Punishment act, together with the British refusal to admit that allegiance and therefore obedience could be discarded; there was above all the growing realization that disturbances in the Cape were in part the consequence of upheavals in Natal. At first British policy was dangerous by reason of its uncertainty. The Whig government was on its last legs by 1839 and fell in Sept. 1841. Between 1839 and 1846 there were five different secretaries of state for war and colonies. Though permanent officials like James (afterward Sir James) Stephen exercised great influence, decisions at cabinet level had always to reckon with parliament. The slowly forming convictions as to what was the right policy were tempered by practical politics and the already heavy drain on Britain's financial resources. In the circumstances, with changing fronts in South Africa and changing fronts at Whitehall, it was difficult for policy to crystallize. Between Dec. 1838 and Dec. 1839 Durban had been reoccupied and held. The military crisis over, the order came to withdraw the British forces from Durban in Dec. 1839. The republican flag was thereupon hoisted. But at the end of 1840 the Natalians sent a commando against Ncapaai, who with his Bushmen allies had raided republican cattle. This disturbed local opinion because of the scale of the plunder, which included "apprentices" taken in defiance of the Punishment act. It also alarmed Faku, chief of the Amapondo, to reassure whom, in Jan. 1841, Captain T. C. Smith was sent with a small force to the Umgazi river. Hitherto the colonial office had toyed with the proposal of Pretorius that the republic should be officially recognized. But in Dec. 1841 came the news that in August the *raad*, harrassed by the unceasing flow of native refugees, had decided to evict them and settle them in the disputed territories between the Mtamvuna and the Umzimvubu, the tinderbox of conflict. To avert this, in May 1842 Smith was ordered to reoccupy Durban. His leisurely advance gave the republicans time to organize, and Smith was besieged so closely at the port that only the heroic ride of Dick King to Grahamstown for reinforcements averted disaster. Col. A. J. Cloete rushed up reinforcements by sea and resistance collapsed. In June the republicans submitted. One year later Henry Cloete (brother of A. J. Cloete) arrived as special commissioner and thenceforward though the *raad*, shorn of its more virile members, continued to function until Oct. 1845, in theory the administration was British, the land settlement was liable to revision and the principle of legal equality was pronounced. In Aug. 1843 Panda, all claim to European suzerainty being tacitly dropped by Britain, accepted the Tugela river as his frontier and confirmed the cession of St. Lucia bay. This fixed the northern boundary of Natal. To the south, the Umzimkulu was fixed as the boundary and beyond it Faku, having disposed of Ncapaai, was given treaty status and recognized as ruler between the Umzimkulu and the Umtata rivers. When it is recalled that in Dec. 1843 similar treaty status had been given to Adam Kok and Moshesh across the Orange river,

the annexation of Natal to the Cape appears not merely as it obviously was, in part a commercial, in part a humanitarian, move but also as part of a constructive, if abortive, effort to give new stability to frontiers distorted by the Great Trek. On the maintenance of stability combined with flexibility, the well-being of all in southern Africa depended.

In this respect, when the War of the Ax broke out in the Cape in 1846, the annexation proved to have been a wise insurance. Partly because, theoretically, the colonial office would allow no distinction between black and white, and pendant on that a revision of the land settlement was considered necessary, many trekkers withdrew from Natal. It is estimated that by the beginning of 1847 the number of Boer families had shrunk to less than 100. The largest immigration project was that launched by J. C. Byrne who during 1849–51 brought out 2,500 emigrants from Britain.

From Annexation to Responsible Government in 1893.—Though from 1845 onward Natal had a local administration, until 1856 it was substantially an adjunct of the Cape. In 1856 it was given its own legislative council of 4 official members and 12 elected representatives. As the settlers increased, they sought to establish control over the executive by securing more complete control over the revenue. There were two chief bones of contention. In 1856 the crown stipulated that £5,000 annually should be set aside for native development. This was challenged on the constitutional ground that the legislature had incomplete control over expenditure. Secondly, Theophilus (later Sir Theophilus) Shepstone (*q.v.*), first as diplomatic agent, then as secretary of native affairs, was a permanent official and tended to move without consultation with either government or legislature. Overemphasis on the niceties of constitutional theory reached their climax during the depression which coincided with the lieutenant governorship of R. W. Keate (1867–72). Economic crisis, constitutional deadlock, uneasiness in the native areas, the threatened repercussions of the Langalibalele affair (*see* below) resulted in the dramatic intervention of the colonial office which sent out Sir Garnet Wolseley in 1875 to stiffen official control. By dint of "drowning the constitution in champagne and sherry" he added, for a five-year period, eight more official members to the legislature. Between 1845 and 1877 Shepstone built up the Natal pattern of native administration. His influence was at its height when, in 1849, by ordinance, the lieutenant governor was made supreme chief and Shepstone his chief induna. Natal was geographically isolated from the rest of South Africa, the European population was small and its resources slight. Across the Tugela was the powerful Zulu monarchy and within Natal the Europeans were hopelessly outnumbered. Merely to have preserved peace during the crucial period of Natal's growth was a major development. When in 1849 a hut tax of 7*s.* was imposed on the natives, Shepstone supervised its collection. For years the hut tax was the most stable revenue of the colony. During 1851–54 Shepstone sought leave to draw off the natives to districts south of the Umzimkulu and to create, as the trader John Dunn was to do in Zululand, a quasi monarchy. This was vetoed by the colonial office. Instead, he settled about 80,000 natives in fixed locations in Natal, leaving about 50,000 as squatters on crownlands or on private property. In 1864, largely at his instigation, the Native Land trust was created with control over more than 2,000,000 ac. of land. In the same year provision was made for educated natives to apply for exemption from native law. Little attempt was made nor indeed, with deficiency of men and money, could be made, to civilize the tribes, though by the end of the century 188 mission schools were subsidized. Measure of Shepstone's achievement was given when, in 1873, Langalibalele, chief of the Hlubi tribe, settled at the foot of the Drakensberg and rebelled rather than hand in for registration the firearms his young men had earned in Kimberley. In the existing state of tension in South Africa, the revolt was probably intended to touch off a general rising. Its prompt suppression by Sir Benjamin Pine without a ripple of revolt in the rest of Natal is comment enough on the effectiveness of the Shepstone system at that stage of Natal's economic development.

As the European population of Natal in the 1870s was little more than 20,000, the Natalians sought not so much land as a reliable labour supply. Various crops had been sampled; tobacco, indigo, cotton and tea in addition to staple farm products had been tried and found wanting. The future of the colony seemed to turn on the coastal belt which in the late 1850s was found suitable for sugar cane. Many natives, acclimatized to the uplands, could not adapt themselves to the malaria-ridden coastal belt. Most had all they needed without work. In 1860, therefore, and, save for the period 1866–74, without interruption until 1911, coolie labour was recruited in India on a five-year indenture with the option of settling on the expiration of the contract. At the same time free immigrants began to arrive in numbers.

The prosperity of the Natal sugar industry as well as the development of market gardening was substantially due to Indian labour. On the eve of the union in 1910 there were 65,917 free Indians and 42,777 were still under indenture.

Until the 1870s Natal remained relatively isolated from the rest of South Africa. The Drakensberg, though not insurmountable, was a formidable barrier. Across the Tugela lay Zululand and to the south (though Alfred county beyond the Umzimkulu was added to Natal in 1865) lay Pondoland and Griqualand East, both potential storm centres. Communications by sea were not easy. Repeated attempts to make the harbour safe had failed and the coast was often the scene of wrecks until the harbour mouth was narrowed and dredged. Economic impetus was, though, sharply felt in the 1870s and 1880s. The opening of the Kimberley diamond fields (1870) made transportation a profitable venture. The coming of railways facilitated the development of the Natal coal fields and railways in their turn were indebted to the development of the coal mines as well as to the opening of the Witwatersrand gold fields in 1886. By the 1890s Natal had a key role to play in the making of a new South Africa.

From 1875 to 1880, moreover, Natal had been the hub of political crisis. The annexation of the Transvaal (*q.v.*) by Shepstone on the instruction of the earl of Carnarvon, secretary of state for colonies, in 1877 and the Zulu War of 1879 (*see* ZULULAND) were prelude to the first Transvaal War of 1880–81 which was fought and extinguished in the Laing's Nek pass and over the Drakensberg at Majuba (Feb. 1881). The crisis made the Natalians acutely aware of the South African position as a whole and H. Escombe and John (afterward Sir John) Robinson began to press for responsible government. Robinson in particular pressed for a federal union, which, Carnarvon's project having ended so disastrously, he argued should next originate with South Africa. Zululand, after abortive experiments, was annexed to the crown in 1887 and the sensitivity of the foreign office as well as the colonial office to the vulnerability of the South African coast line was shown in the sealing off of the coast by annexation. In 1884 St. Lucia bay was annexed, in 1884 Port St. Johns, in 1885 Galekaland, in 1886 Bomvanaland, in 1894 Pondoland and in 1895 Tongaland.

Economic development and greater security necessarily reacted on internal politics. The retirement of Shepstone in 1877 saw the beginning of a transitional phase in native policy. In 1875 a native high court of three judges had been established, thus separating the judicial from the administrative powers of the secretary for native affairs. A commission was appointed to draw up a code of native law (1878), but in practice magistrates in each district had a wide margin of discretion. There was a growing interest in native administration not altogether then divorced from land hunger and desire to tap more effectively the labour and fiscal potentialities of the natives. Native affairs were more exposed to the exigencies of politics. Codification of native law tended to give rigidity to a tribal structure that economic changes were beginning to undermine.

In 1893 the increase in European colonization and settled development, greater prosperity and, it seems, conviction that the economic prosperity of Natal turned on forging links with the Transvaal, brought to a successful conclusion the demands for responsible government in Natal. The first prime minister was Sir John Robinson (1893–97). He had been a member of the legislative council since 1863 and had represented Natal at the London conference on federation (1876) and at the jubilee celebra-

tions of 1887. In 1888 he had represented Natal at the South African customs conference and had declined to commit Natal to agreements which would have sacrificed the advantages of its geographical proximity to the Rand. In the three years that followed the customs agreement between the Cape and the Orange Free State and the extension of the Cape railway system to Pretoria, Natal revenues shrank by 50% and the colony was crippled by £250,000 interest charges on debt incurred to improve railways and harbours. Natalians tended unwarrantably to blame a non-responsible administration for failure to press Natal's economic interest. The popular response to Robinson's renewed agitation for responsible government was due to popular conviction that the colony's future depended on the exploitation of the Rand market which was only 130 mi. from the Natal border. One reason for this belief was that Natal was still a crown colony, so that obliquely the Natal railway was a "crown" railway, the extension of which was prohibited by the Transvaal after it had reached Charlestown near the border in 1891. Certainly the conclusion of a railway agreement with the Transvaal (Feb. 1894) followed hard on the heels of the establishment of responsible government. In Oct. 1895 the new line was completed to Pretoria.

Economic forces had proven a basic community of interests between the South African states, a conclusion endorsed in Natal which belatedly in 1898 concluded customs agreements with the Cape and Orange Free State. In the same way the native problem was even more clearly an interstate problem, once the mines at the Rand became dependent on migratory native labour. Two things ruptured the approach to a common South African point of view. One was the cultural revival of Afrikaner nationalism which fixed its political hopes on the republics; the other was the gross and inexcusable blunder of the Jameson raid (Dec. 1895; *see* TRANSVAAL). Thus, though in 1897 Natal, as befitted its new status, assumed responsibility for Tongaland and Zululand, the necessary readjustments had hardly been made when, in Oct. 1899, the South African War struck at the foundations of South African co-operation. Natal was invaded by the Boers but the defense of Ladysmith, as well as the reinforcements hurried from overseas through the port of Durban, prevented the colony from being overrun. Natalians played an important part both in the civil and the military organization of the war. On its conclusion the districts of Vryheid, Utrecht and parts of Wakkerstroom were reattached to Natal. Utrecht, settled and founded by Boers in 1848, had been enlarged by agreements with Panda in 1861. While in 1884, also at the expense of Zululand, Vryheid had been founded and, with frontiers cut off from the sea by the British annexation of St. Lucia bay, had, to the exasperation of Natal, been recognized *faute de mieux* by Britain in 1884. Natal had made considerable efforts and sacrifices during the war and though it is arguable that as a colony its interests had on occasion either been ignored or even subordinated to those of the Cape and to the shifting trends of British colonial policy, its territory had been doubled since 1897 and then coincided with the boundaries envisaged by the trekkers.

Peace of Vereeniging to the Union of South Africa, 1910.—The peace of Vereeniging which ended the South African War was followed by the grant first of representative and then of responsible government in the Transvaal and the Orange River colony. This made the problem of evolving some kind of economic and political co-ordination as urgent as it had been before the war. Natal statesmen played a prominent part in the intercolonial conferences which preceded the union. In 1906 the Bambata rebellion was a sharp reminder that more was at stake than railway rates and customs. Responsible government in Natal had brought with it a tendency to subordinate native affairs to the exigencies of party politics, while the rapid development of commerce and industry brought natives more sharply up against European notions of contract reflected in the Masters and Servants regulations. The migration of native labourers first to Kimberley, then to the Rand or, nearer home, to the coal fields of Natal was unsettling. First locusts, then rinderpest, then war had dislocated agriculture. Squatters' rents had gone up, the cost of living, even at Zulu levels, was rising and the poll tax of £1 a head imposed on all males, native and European, over the age of 18 was, though theoretically it treated all races equally, resented by the natives on whom it placed a disproportionate burden. There had been, too, much anti-white agitation. When, therefore, the attempt to collect the tax led to the killing of two European policemen at Byrnetown, there were signs and fears of a general rising. The arrested natives were tried and sentenced by court-martial, but Lord Elgin, secretary of state in the Campbell-Bannerman ministry, ordered stay of execution. The Natal protest that this was a violation of the rights of self-governing colonies received commonwealth support and Lord Elgin gave way. More serious was the threatened spread of the revolt through the attempt of Bambata to rouse Zululand. In less than six months the revolt was isolated and suppressed, but isolated events convinced Natalians that Dinizulu was implicated. He was arrested in Dec. 1907 and thanks to the skilled advocacy of W. P. Schreiner he was acquitted of most of the charges levied against him. The revolt had been promptly handled and Natal had received the active support of the other South African colonies. It is to the credit of Natal that the revolt caused some heart searching. A special commission was appointed in Aug. 1906 to inquire into the whole position and more than 5,500 natives attended and 901 native statements were recorded in the schedule attached to the report. Its analysis recognized the defects in native administration, in particular the loss of personal contact, the increased and often confusing regulations (there had been 48 new regulations since 1893) and the subordination of native affairs to political pressures. One sentence in particular was long to be pertinent: "As we can neither assimilate or destroy them, political forethought and commonsense alike call for a settlement of the question on a broad, enlightened permanent basis." It seems fairly certain that Natal's approach to the union was coloured by the experiences of 1906. The need for union on economic grounds was clear. The advantage of a strong front in view alike of the Indian and the native question was also clear, but Natal was sceptical of Cape liberalism quite as much as of Transvaal nationalism and strove vainly in the National convention which preceded union to substitute federation for an incorporating union. Natal was the only colony which held a referendum on the question of union. It was accepted by 11,121 votes to 3,701. For the subsequent history of Natal, *see* SOUTH AFRICA, REPUBLIC OF: *History*. (W. A. ML.)

POPULATION, ADMINISTRATION AND ECONOMY

Population.—In 1960 the population of Natal was 2,979,920, comprising 340,235 whites, 2,199,578 Bantu (a term that has officially replaced "native" or "African"), 394,854 Asians and 45,253 Coloureds. Of these, 85% of the whites, 85% of the Coloureds, 78% of the Asians and 18% of the Bantu were urban dwellers. It is thus clear that in Natal the whites, Asians and Coloureds are preponderantly urban; the Bantu preponderantly rural. Of the rural Bantu in 1951 about 366,000 were on white farms, 31,000 on farms of Asians and Coloureds and 90,000 on other farms and agricultural holdings. About 955,000 lived in Bantu areas consisting mainly of homelands, Trust land, mission stations, tribally owned farms and crown land. In the homelands, covering 11,211 sq.mi., the Bantu population was 925,610, giving a mean density of 83 to the square mile, but densities varied from about 50 in northern Zululand and Tongaland to about 140 in the southern coastal zone. The chief towns are Durban (pop. [1960] 681,492) and Pietermaritzburg (128,598) (*qq.v.*).

Administration.—The relationship of the provinces to the central government is described under SOUTH AFRICA, REPUBLIC OF. The Natal provincial council's responsibilities include provincial hospitals, certain municipal powers, shop hours, loans to municipalities and health committees, entertainment duty, water supply, education and teachers' pensions. The main items of its revenue are personal, income and company taxes, automobile registration fees and taxes, hospital receipts, totalizator and entertainment taxes. In addition there are considerable subsidies from the central government and a smaller amount from the department of transport for national roads. The main items of expenditure are education, hospitals and health services, roads, bridges, etc., and national roads. For purposes of administration

the province is divided into 44 magisterial districts.

Public Health.—The Natal provincial administration controls 20 hospitals and hospital advisory boards, and representatives of various interests are appointed to assist with the control of these hospitals, which are maintained solely at public expense. Many institutions not controlled by government authorities also receive financial assistance from provincial funds.

Education.—There are more than 160 primary and intermediate schools for whites, most of which are maintained by the state or are state-aided. Secondary and high schools are also similarly maintained. For Asians and Coloureds there are nearly 300 primary and intermediate schools, and some secondary and high schools. There are also several private schools. Bantu schools number more than 1,400. The University of Natal (founded 1909 as a constituent college of the University of South Africa, assuming university status in 1949), the chief institution of higher education in the province, is located partly in Pietermaritzburg and partly in Durban. Students include whites, Asians, Coloureds and Bantu.

The Economy.—*Agriculture.*—By far the most valuable crop is sugar cane, which is grown on the coastal lowlands and forms one of the principal agricultural products of the country. Maize (corn) is grown mainly in the uplands; the total yearly crop is approximately 2,000,000 bags (of 200 lb. each), the most productive districts being Estcourt, Newcastle, New Hanover, Bergville and Utrecht. Some of the best yields in South Africa are obtained in the midlands, where the average yields are five–six bags to the acre; on some farms seven–eight bags are usual. Except for kafir corn (kafir or sorghum), which is grown mainly on Bantu lands, the only other important crop is cotton, which does well under irrigation in the Ngotshe district, where production averages about 3,000,000 to 4,000,000 lb. per year, and in the Lower Umfolozi district, with about 1,000,000 lb. Pastoral farming is practised mainly in the midland and highland areas, where most of the cattle are pastured. The Bantu herds outnumber those of the whites by about 90%. Sheep are raised in the greatest number in the high veld districts of Utrecht, Klip River and Newcastle.

Mining and Industry.—Coal production is the most important mining activity. Derived from the middle Ecca beds of the Karroo system, the Natal coals include some of the best types in South Africa and, because of the great intrusions of dolerite, there are large deposits of anthracite. Most of the coal and anthracite produced (about 5,000,000 tons a year) comes from two coalfields: the Klip River field centred on Glencoe, including Newcastle and Dundee, and the northern Natal field, with Vryheid as its main producing centre. In the coastal zone titanium is mined at Isipingo, the production being about 30 tons a day. The production of ilmenite, zircon (for ceramics) and rutile was also beginning in the mid-20th century in the south coastal areas.

Almost all manufacturing industry takes place in the Durban and Pinetown industrial area. Products include textiles, soap, rubber, cigarettes, fertilizers, paint, clothing and furniture. Other establishments include a ferromanganese plant at Cato Ridge, a rayon factory at Umkomaas, an oil refinery at Wentworth, a cotton factory at New Germany and a textile factory at Pinetown. At Pietermaritzburg is the tanning extract factory—probably the largest in the world. A further industrial area has been laid out at Mountain Rise, while at Howick is a notable rubber factory, at Ladysmith cotton factories and at Empangeni, in Zululand, a pineapple cannery.

Power is provided by the Electricity Supply commission's Natal Southern and Natal Central undertakings, of which the Congella (Durban) and Umgeni power stations and the Colenso undertaking operate together.

An important marine industry is whaling, producing annually products to the value of about R. 6,000,000. To meet the industrial developments, improvements in Durban harbour have included rail and road access to the Island View oil sites and new precooling and cargo sheds.

Communications.—Natal has a network of communications including 1,539 mi. of railway line and 503 mi. of bituminous surface main roads. Durban (*q.v.*) is South Africa's most important harbour and Ladysmith is a main rail junction. The Louis Botha National airport is near Durban.

See also references under "Natal" in the Index. (J. H. Wn.)

NATAL, chief city and capital of the state of Rio Grande do Norte, Brazil. It is located a little more than 5° S. of the equator, on the right bank of the Rio Potengí about 2 mi. above the river's mouth. Pop. (1961) 154,276. Natal is connected by rail with the interior of the state and southward to João Pessoa, Recife and Maceió. Its chief overland connections, however, are by all-weather gravel highways which reach all the major points in the northeast of Brazil and extend southward to Rio de Janeiro. During World War II, Natal was a stage in the ferry route over which planes from the U.S. were flown to Africa and southeast Asia. Natal is also the port through which the products of the state are sent to other parts of Brazil. The chief products are cotton, sugar, salt and hides. In the city there are plants for the manufacture of cotton textiles and for the refining of salt. The city was founded by the Portuguese in 1599. (P. E. J.)

NATCHEZ, a Muskogean-speaking tribe formerly living in nine villages on the east side of lower Mississippi river between the Yazoo and Pearl rivers, near the site of the present city of Natchez, Miss. Early in the 18th century when the French first established themselves in what was later called the Natchez district, the tribe numbered perhaps 6,000. Relations with the French were at first friendly, and under Jean Baptiste Le Moyne, sieur de Bienville, governor of Louisiana, Ft. Rosalie was built on the site of the present city of Natchez. In 1723 the Natchez were nearly conquered by the French, and an unsuccessful uprising of the Natchez in 1728 was followed in Nov. 1729 by the massacre of more than 200 Frenchmen and the destruction of Ft. Rosalie. In the war that followed the French enlisted the aid of the Choctaw tribe, drove the Natchez from their villages and scattered them. More than 400 Natchez were captured and sold into the West Indian slave trade; the remainder took refuge with the Chickasaw, and later with the Creek and Cherokee. A few Natchez lived in northeastern Oklahoma in the 1960s.

The Natchez, allied in general culture to other Muskogean tribes, were primarily agricultural, highly developed in the arts, and exerted considerable influence on neighbouring tribes before their dispersal. They had developed a sun worship with which was related a perpetual fire of oak bark in a temple. The fire, as well as all fires in the villages, was allowed to die once a year on the eve of the harvest festival and was renewed at dawn on the festival day by a high priest who made fire by rubbing two sticks together. All the village fires were then made anew from this fire. The women then bore in the first maize, some of which was offered at the temple and some of which was ground and baked into bread for a ceremony at sunset. The ceremony was followed by general feasting.

The remarkable Natchez caste system classified men as suns, nobles, honoured people and commoners (or stinkards). The tribal chief (the Great Sun) and heads of the villages claimed descent from the sun; and there were both male and female suns, each supposedly descended from a male and female who had come out of the sun. The system was matrilineal and exogamic. Male and female suns could not marry each other. Male suns married stinkard wives and their children were honoured people. Sun women married stinkard husbands and their children were rated suns. The Great Sun had the power of life and death over all the others and was followed in death by his spouses, attendants and voluntary victims. The succeeding tribal chief was the son of the Great Sun's sister or closest female relation.

See H. B. Cushman, ***History of Choctaw, Chickasaw and Natchez Indians*** (1961).

NATCHEZ, a city of Mississippi, U.S., is located on the Mississippi river near the southern boundary of the state; the seat of Adams county. Founded by France as an outpost bastion of empire, Natchez has been part of the struggle for colonial mastery in North America and is symbolic of the south with its rich ante-bellum cotton culture, post-Civil War decline and modern industrialization.

The oldest settlement on the Mississippi river, the site was

selected in 1700 as one of a series of military posts designed to halt British westward penetration, with actual settlement occurring in 1716. Surviving a massacre by Natchez Indians in 1729, one of the bloodiest in American history, the settlement passed to the British in 1763 at the conclusion of the French and Indian War. Becoming Great Britain's chief outpost on the Mississippi, Natchez was a haven for Loyalists driven from the revolting colonies during the early stages of the American Revolution until, in 1779, the town was captured by Spain. Spanish cession occurred in 1795, and with occupation by the United States in 1798 Natchez became the first incorporated town (1803) and the first capital of the Territory (1798–1802) of Mississippi. It was also the southern terminus of the famed Natchez Trace, the overland link between Natchez and Nashville, Tenn. As the old southwest was settled, Natchez burgeoned as the commercial and cultural centre of a vast and rich cotton-producing area. At the outbreak of the American Civil War it was the largest and wealthiest city in Mississippi.

Following a decline after the Civil War, modern Natchez has capitalized upon its natural resources, industrial potential, and historic legacy to become again one of Mississippi's leading cities. Transportation facilities include river, railway, highway and airline systems. A $40,000,000 bridge spans the Mississippi at Natchez. Timber, petroleum and natural gas reserves have attracted major manufacturers of rubber, wood, paper and textile products as well as producers of petroleum and natural gas.

Possessing a legacy of the cotton barons' magnificent homes, sunken roads, an infamous though long extirpated river front section named "Natchez-Under-the-Hill" and a culture ranging from the supreme elegance of the "Cotton kingdom" to the lawlessness of the early river front, Natchez has become the stereotype of the ante-bellum south. The annual Natchez pilgrimage, held during March and featuring homes and pageants of those days, attracts visitors from throughout the United States. Many novels and motion pictures have their setting in the city.

The city contains several parks, the largest of which was once part of Auburn and Sunnyside plantations; also three hospitals, the Fisk public library and Natchez college, a Negro Baptist junior college opened in 1885. For comparative population figures *see* table in MISSISSIPPI: *Population.* (P. F. WA.)

NATHAN, GEORGE JEAN (1882–1958), U.S. author, editor and drama critic, of whom, at the time of his death, the *New York Times* reported ". . . no other American critic of the period had so greatly raised the standards of play producers or so determinedly elevated the tastes of play goers." He was born Feb. 14, 1882, in Fort Wayne, Ind., son of Charles and Ella (Nirdlinger) Nathan. He graduated from Cornell university, Ithaca, N.Y., in 1904 and joined the staff of the *New York Herald.* Beginning in 1906, he was at various times drama critic for numerous magazines and newspapers, but his name is particularly associated with *Smart Set,* of which he was co-editor (1914–23) with H. L. Mencken, and with the *American Mercury,* which, also with Mencken, he helped to found (1924). As a critic Nathan championed the plays of Ibsen, Strindberg, Shaw, O'Neill, O'Casey and Saroyan. He published his *Theatre Book of the Year* annually from 1943 through 1951, as well as more than 30 volumes of lively essays on theatrical and other subjects.

Nathan married the actress Julie Haydon in 1955. He died in New York city on April 8, 1958. (B. HT.)

NATHANAEL, one of the first disciples of Christ, "an Israelite . . . in whom there is no guile" (John i, 47). He was an inhabitant of Cana in Galilee (John xxi, 2), but is otherwise unknown. Though Nathanael was one of the first disciples, his name does not appear in the apostle lists. A 9th-century Syrian tradition identified him with Bartholomew—so Isho'dad of Merv, Elias of Damascus and others. (*See* BARTHOLOMEW, SAINT.) This identification was adopted by Rupert of Deutz in the 12th century and became common from that time on in the Western Church; it is commonly accepted by modern biblical scholars. The name means "God has given." (J. A. FI.)

NATHANYA (NETANYA), a town of Israel situated on the coastal plain of Sharon, 25 mi. N. of Tel Aviv-Jaffa. Founded in 1928 as an agricultural village of smallholders, it was named after Nathan Straus, a well-known U.S. philanthropist. Pop. (1961) 41,267. It became a popular bathing resort for the region, and British forces had a big rest camp there in World War II. Many diamond cutters and polishers from the Netherlands and Belgium were settled in a suburb to carry on the diamond industry, and other important industries (textiles, chemicals, paper products, food processing) have been developed. The Goldmunz Museum of Modern Art is in the southern part of the town. The park by the sea includes an open-air theatre. There is good road and railway communication with Tel Aviv-Jaffa. (No. B.)

NATICK, a city of Massachusetts, U.S., 18 mi. W.S.W. of Boston, is situated on the southeast end of Lake Cochituate. The area was granted to John Eliot (*q.v.*) in 1650 as a plantation where he could carry on his mission work and establish a school of higher education for the most capable Indian converts; Natick was its original Indian name. Eliot published his Indian Bible in 1663, a copy of which the town possesses. The Indians held the land in common until 1719 and prevailed until 1762. Incorporation as a town took place in 1781. Modern Natick serves in a dual capacity as a suburban residential community and as a growing industrial town. Of special interest is the research and engineering centre of the U.S. army quartermaster research and development command. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (M. E. L.)

NATION, CARRY AMELIA (née MOORE) (1846–1911), U.S. temperance advocate, was born in Garrard county, Ky., Nov. 25, 1846. In 1867 she married Charles Gloyd, an alcoholic; their brief unhappy life together prompted her later career of saloon-smashing in Kansas. With a few hymn-singing women, or alone, she would march into a saloon, sing, pray, hurl vituperations at all "rummies" present and smash the fixtures and the stock with hatchets. This crusade, most violent in the 1890s, led to scattered temporary efforts at law enforcement. After this period of "hatchetation" of "joints"—her words—she lectured in many states, in Canada and Great Britain, usually under her own management. For a while she also spoke between acts of carnivals and burlesque shows.

BROWN BROTHERS

CARRY NATION

The fact that her first husband had been an active member of a fraternal order as well as an alcoholic led her to fight such organizations along with saloons, and she added to her list of things to be destroyed tobacco, foreign foods, corsets, skirts of improper length and paintings of the sort often found in barrooms. She was an advocate of women's suffrage, but neither the national movement for suffrage nor that for temperance gave her much support. Her second husband, David Nation, divorced her in 1901 on grounds of desertion after a marriage of 23 years. She died June 9, 1911. Her autobiography, *The Use and Need of the Life of Carry A. Nation* (1904), is a hodgepodge of disorder. (G. BN.)

NATIONAL ACADEMY OF SCIENCES–NATIONAL RESEARCH COUNCIL. The academy, a nongovernmental U.S. organization of scientists, was established March 3, 1863, by act of Congress to serve as an official adviser to the government, upon request, in all matters of science and technology. The National Research Council was established by the academy in 1916. The academy and the council were unified after World War II and came to be known as the National Academy of Sciences–National Research Council (NAS–NRC, or Academy–Research Council).

Among the first tasks assigned to the academy were those dealing with weights, measures, and coinage, magnetic deviation and bottom-fouling in iron ships, wind and current charts and sailing

directions, materials for the manufacture of coins, the prevention of counterfeiting, and the establishment of metric standards for the states. Later, the academy was asked to advise on plans for observing the transits of Venus in 1874 and 1882. In 1871 it prepared instructions for the scientific activities of the expedition which sailed toward the North Pole, in 1873 for the exploration of the Yellowstone, and in 1902 for the exploration of the Philippines. In 1878 the academy made recommendations that resulted in the creation of the U.S. Geological Survey; later, academy advice led to the establishment of the Weather Bureau, the Smithsonian Astrophysical Observatory, and the National Bureau of Standards; and academy recommendations played a leading role in the establishment of the U.S. Forest Service.

In 1916, at the request of Pres. Woodrow Wilson, the academy established the National Research Council to attack problems arising from the shortage of nitric acid and organic chemicals and from urgent needs in communications and preventive medicine. The council was active in the development of devices useful in antisubmarine warfare and in directing antiaircraft fire, in the development of effective insecticides, and in the testing of lenses and the production of optical glass. The council also participated in the investigation of traumatic shock and the development of procedures for the selection of officers and the classification of draftees.

Among the steps of lasting significance taken during the years immediately after World War I were the launching of the extensive program of National Research Council fellowships to enable young scientists to receive postdoctoral research training. The council inaugurated a Highway Research Board to provide a modern technological base for the development of a national highway system, and published between 1926 and 1933 the eight volumes of the *International Critical Tables of Numerical Data, Physics, Chemistry, and Technology.*

So great was the effort required by World War II that a group of academicians persuaded the federal government to establish its own agency, the Office of Scientific Research and Development, providing for appropriate links with the academy. Among the accomplishments of the resulting collaboration were the recommendations of an academy committee that an intensive drive for the military application of nuclear fission be pursued; recommendations on the large-scale production of penicillin, the development of quinine substitutes, the battlefield use of sulfa drugs and the use of human blood plasma in transfusions; on the design of adequate defenses against the possibilities of biological warfare; on the stockpiling of strategic materials; on research in metallurgy and mineral technology; on the selection and training of aircraft pilots and of specialists in radar and electronics; and on problems relating to human nutrition and aviation medicine.

The impact of World War II subordinated for a time the academy's role as a learned society. Funds from governmental sources rose from 6% of the entire budget of the academy and the council in 1939 to 62% in 1948. During the same period total annual expenditures increased from a little over $700,000 to more than $3,100,000. In the 1960s these reached $15,000,000 a year. The rapidly increasing demands upon the academy after World War II resulted in its reorganization as the National Academy of Sciences–National Research Council, in which the members of the academy are trustees as well as participants, and the council is made up of representatives of the great national scientific and engineering societies and of the government. Several thousand scientists and engineers participate in the activities of the overall organization. Among the undertakings of the Academy–Research Council were the inauguration of the Atomic Bomb Casualty Commission (to study the long-term effects of the bombings in Hiroshima and Nagasaki) and a series of extensive engineering tests of highway construction. Some of the academy's major activities have stemmed from the deepening involvement of science in many facets of public policy. In 1955 a continuing survey of the biological effects of atomic radiation was undertaken with private support. Reports emanating from this study set forth the state of knowledge in specialized fields for the benefit of scientific workers and summarized the situation in nontechnical language for the education of the public in the biological problems accompanying the advent of the atomic age. Other areas of public concern into which the academy has looked include federal support of science, world population problems, civil defense, personal loyalty requirements relating to the award of governmental research grants, railroad and urban transportation, the utilization of technical and scientific manpower, and—at the request of Pres. John F. Kennedy—research needs and opportunities in the field of natural resources.

NATIONAL ARBITRATION TRIBUNAL: *see* Industrial Court.

NATIONAL ARCHIVES, U.S. The National Archives and Records Service, part of the General Services Administration, consists of the National Archives, the Office of Federal Records Centers, the Office of Records Management, the Office of the Federal Register, and the Office of Presidential Libraries. It is headed by the archivist of the United States, who is also chairman of the National Historical Publications Commission.

The National Archives preserves, describes, and services federal records retained because of their enduring value. It holds the nation's most important records dating from about 1774. They include the original laws, executive orders, and proclamations, treaties, records of the Congress and virtually all the permanently valuable records of federal executive agencies. The holdings, most of which are freely open for research, are described in finding aids published from time to time. Records of high research value are available to scholars and research institutions on microfilm. The Declaration of Independence, the Constitution of the United States, the Bill of Rights, and many other historic documents are on display in the National Archives Building.

The Office of Federal Records Centers is responsible for the appraisal of records, for the economical maintenance of noncurrent records, and for assisting agencies with the efficient management and disposition of their records. The Office of Records Management is responsible for developing and promoting improved paperwork practices throughout the government.

The Office of the Federal Register publishes the daily *Federal Register*, the *Code of Federal Regulations*, the *United States Statutes at Large*, the *United States Government Organization Manual*, and the *Public Papers of the Presidents of the United States*, all obtainable through the Government Printing Office.

The Office of Presidential Libraries administers the Franklin D. Roosevelt Library at Hyde Park, N.Y., the Harry S. Truman Library at Independence, Mo., the Dwight D. Eisenhower Library at Abilene, Kans., and the Herbert Hoover Library at West Branch, Iowa. Papers of these presidents and many of their associates are housed in the libraries and contain significant materials for the study of modern U.S. history. After President Kennedy's assassination, preparations were made for the establishment of the John F. Kennedy Library at Boston.

The National Historical Publications Commission promotes and participates in documentary publication programs of public and private agencies. Projects for publishing papers of such men as Benjamin Franklin, John Adams, John Quincy Adams, Alexander Hamilton, and James Madison have been set up under private sponsorship. The commission itself undertook preparation of a documentary history of the ratification of the federal constitution and the Bill of Rights. (W. C. G.)

NATIONAL ASSOCIATION FOR THE ADVANCEMENT OF COLORED PEOPLE, a U.S. voluntary interracial organization founded to combat racism, stamp out lynching and lynch law, eliminate racial discrimination and segregation, and assure Negroes their constitutional rights. In response to a call issued by 60 Negro and white educators, clergymen, and other leaders on Feb. 12, 1909—the centennial of the birth of Abraham Lincoln—a national conference on the Negro was held in New York City on May 30–June 1 of that year. The conference idea had been conceived by William English Walling, a journalist, and nurtured by two social workers—Mary White Ovington and Henry Moskowitz—with Oswald Garrison Villard, grandson of William Lloyd Garrison. Out of this conference the National Association for the Advancement of Colored People (NAACP) was born.

Since its founding, the NAACP has sought its goal through legal action to protect the rights of Negro citizens, nonpartisan political action to secure enactment of civil rights laws, a program of education and public information designed to win popular support, and direct action to achieve specific goals. By the second half of the 20th century the NAACP had become a nationwide association of more than 400,000 members in over 1,600 local units in 50 states and the District of Columbia. Headquarters were maintained in New York City with a bureau in Washington and regional offices in Atlanta, Dallas, Kansas City, Mo., and San Francisco. Its monthly organ, *The Crisis*, had a circulation of more than 130,000.

See further NEGRO, AMERICAN.

See Langston Hughes, *Fight for Freedom: the Story of the NAACP* (1962); Wilson Record, *Race and Radicalism: the NAACP and the Communist Party in Conflict* (1964). For current history, *see* the *Britannica Book of the Year*. (Ro. C. W.; Ro. W.)

NATIONAL ASSOCIATION OF EVANGELICALS, a fellowship of various evangelical Protestant groups within the United States, was organized in 1943 in response to a "Call to Evangelical Action" signed by 147 evangelical leaders. It comprises more than 40 denominations, many independent religious organizations, local churches, groups of churches, and individual Christians. All members must subscribe to a Statement of Faith which requires belief in the "Bible as the inspired, the only infallible, authoritative word of God" and commitment to a well-defined category of fundamental Christian doctrines.

The association renders services in the major fields of Christian activity, with commissions and affiliated agencies for evangelism and church extension, higher education, Christian day schools, Sunday schools, publications, foreign missions, laymen's work, women's work, youth work, public affairs, radio and television broadcasting, government chaplaincies, world relief, international relations, social action, stewardship, spiritual life, and theological concerns. Among its related agencies are the Evangelical Foreign Missions Association, the National Sunday School Association, the National Religious Broadcasters, Inc., and the National Association of Christian Schools.

The association claims 2,500,000 full members and a service constituency of more than 10,000,000. Its national headquarters office is at Wheaton, Ill. Other offices are in Washington, D.C., New York City, and other major U.S. cities. The organization is officially related to the World Evangelical Fellowship, with offices in London. *See* also FUNDAMENTALISM.

See James DeForest Murch, *Cooperation Without Compromise: a History of the National Association of Evangelicals* (1956); J. Elwin Wright, *Evangelical Action* (1943); and the monthly journal, *United Evangelical Action*. (J. DeF. M.)

NATIONAL ASSOCIATION OF MANUFACTURERS (U.S.): *see* TRADE ORGANIZATION.

NATIONAL CONVENTION. National conventions of the Democratic and Republican parties are held at four-year intervals to nominate the party candidates for president and vice-president of the United States. The conventions, as the representative organs of the parties, also adopt platforms, elect the national committees and may adopt rules governing the national organization of the parties and their work between conventions. In practice, the conventions also act as rallies for the presidential election campaigns. Disagreements within the parties often lead to heated argument at the conventions but also usually to reconciliation and greater cohesion as each party unites behind the chosen leadership. The public image of the parties on the eve of the presidential election is in large measure the product of the conventions.

Early History.—The conventions originated during the presidency of Andrew Jackson (1829–37), after years of growing dissatisfaction over nominating procedures. The first president, George Washington, was so clearly the outstanding national leader of his time that no formal action was necessary to identify him as a candidate before his election. But when it became necessary to choose a successor among several candidates, it became apparent that somehow the field of choice must be narrowed as a preliminary step, if the electoral arrangements of the constitution were to operate effectively. By the election of 1796, the beginnings of party organization in congress were able to solve the problem; presidential nominations were then made mainly in informal congressional party caucuses until 1816, when James Monroe was nominated and elected.

Monroe's administration was marked by a virtual disappearance of such organized political parties as had previously existed in congress. In 1820 Monroe required no nomination for a re-election that was almost by unanimous consent; but in 1824 the popular vote was divided among four candidates, none of whom had a majority, and the election was thrown into the house of representatives for settlement. John Quincy Adams was chosen president, although Andrew Jackson had been the leading candidate. By 1828 the Jackson men were so strongly organized that no formal action was needed to identify their candidate, although there had been talk of calling a national convention. Jackson won the presidency in 1828 without difficulty. A clarification of party lines followed in congress, but the congressional party caucus was too discredited for restoration as a nominating agency.

The opposition parties of the time held the first recognized national party conventions in preparation for the elections of 1832. The Antimasonic party met at Baltimore, Md., in Sept. 1831, with 116 delegates from 13 states and chose William Wirt. The National Republican party, generally identified as a predecessor of the Whig party and the present Republican party, held a convention at Baltimore in Dec. 1831, at which it nominated Henry Clay. The Jacksonians met at Baltimore in May 1832 as the "Democratic-Republican National convention," hailed Jackson as their chief and nominated Martin Van Buren for vice-president. This was the first national convention of the present Democratic party.

The National Republicans held no convention in 1836 and were replaced in 1840 by the Whigs, who held national conventions through 1852. After that year the Whig party disintegrated over the issues of slavery. It was succeeded mainly by the Republican party, which held national conventions in preparation for every presidential election from 1856. Third parties and minor parties also held national political conventions; but as generally used, the term refers to the conventions of the two major parties.

Nominating Patterns.—Franklin Pierce, defeated for renomination in 1856, was the only elected president who tried and failed to win a second nomination from the national convention of his own party. But others of the period declined the effort. James K. Polk had announced himself as a one-term president; and James Buchanan thought better of any second-term attempt.

After the turn of the century, it was generally expected that an incumbent first-term president would seek renomination and achieve it easily. The "Bull Moose" drive to prevent the renomination of William Howard Taft in 1912 was the main exception; and Taft was renominated in the end, although he lost the election. Franklin D. Roosevelt won a third-term nomination in 1940 with relatively little difficulty, and a fourth in 1944 with none at all. But under the 22nd amendment to the constitution, adopted in 1951, further third-term nominations were prohibited, except for a vice-president who becomes president and serves no more than two years in his first term.

All of the eight vice-presidents who succeeded to the higher office through death of the president through 1963 sought nominations to succeed themselves. The four who made the effort during the 19th century—John Tyler, Millard Fillmore, Andrew Johnson and Chester A. Arthur—were rejected by their parties. Four in the 20th century—Theodore Roosevelt, Calvin Coolidge, Harry S. Truman and Lyndon B. Johnson—won renomination.

Nominations by the party out of power have only rarely resulted in the renomination of a previous candidate. After Van Buren's failure to secure a third nomination in 1844, and Clay's final nomination in that same year, no "titular leader" of a defeated party was seriously considered for renomination until Grover Cleveland's third nomination and second election in 1892. William Jennings Bryan was nominated in 1896, 1900 and 1908, but lost the elections that followed in each case. Alfred E. Smith sought a second Democratic nomination unsuccessfully in 1932, and Wendell Willkie sought a second Republican nomination unsuccessfully

in 1944. In 1948, Thomas E. Dewey became the first defeated Republican to receive a second nomination, but was again defeated; in 1956, Adlai E. Stevenson was renominated by the Democrats, and was also defeated.

The conventions have nominated occasionally with little or no contest even when no president or titular leader was available. Instances of this kind have included a few rare nominations that were akin to inheritance as a means for acquiring party leadership: Van Buren's first presidential nomination, in 1836; Taft, 1908; Herbert Hoover, 1928; Richard M. Nixon, 1960. Other instances have included the designation of an already obvious party choice: Clay in 1832 and 1844, Smith in 1928.

A few other nominations have involved enough agreement among the inner groups of party leaders to make the work of the conventions relatively simple. Among the Democrats, such nominations have included those of Lewis Cass, 1848; George McClellan, 1864; Horace Greeley, 1872; Winfield S. Hancock, 1880; Cleveland's first nomination, 1884; Alton B. Parker, 1904. Republican nominations of this type have included those of John C. Frémont, 1856; Ulysses S. Grant, 1868; Charles Evans Hughes, 1916; and Alfred M. Landon, 1936. Inner-group selections of the kind just noted have rarely won elections, however.

New leadership was selected after a vigorous contest in 27 of the 67 major party conventions through 1964. Each of these contests involved at least two and often three or four leading candidates for the presidential nomination of the party concerned. In 20 cases, the prize was captured by one of the major contestants. In the other seven cases of contest, compromise or "dark horse" candidates were selected after rejection of all the leading candidates. These include the cases of Polk, 1844; Pierce, 1852; Horatio Seymour, 1868; Rutherford B. Hayes, 1876; James A. Garfield, 1880; Warren G. Harding, 1920; and John W. Davis, 1924. In addition, Benjamin Harrison (1888) and Bryan (1896) have sometimes been regarded as "dark horse" candidates, but were in no sense the result of interfactional stalemate and compromise. Willkie (1940) has also been considered a "dark horse" candidate, but was conspicuously in the running before the convention opened and was not a compromise.

After the 1920s, the factors producing the "dark horse" candidacies of the past disappeared or changed considerably. In 1936, the Democratic party abandoned its century-old rule requiring a two-thirds vote of the convention to nominate. Under a regime of majority voting in both party conventions, with increasingly open campaigning before the conventions by willing candidates and with the clarification of preconvention campaigns and candidate status that takes place through public opinion polls, preconvention primaries and modern processes of communication, national conventions can usually reach their decisions quickly—unlike the Democratic convention of 1924, which required 16 days and 103 ballots under the two-thirds rule to nominate a candidate.

Sources of Candidates.—Candidates for the nominations have usually been persons with extensive political experience; although in rare instances others have been considered and nominated, as in the case of Willkie (1940), and even elected, as in the case of Dwight D. Eisenhower (1952). U.S. senators have formed the largest single category of contestants for both the presidential and vice-presidential nominations. Nominations for the lesser office were won by senators with increasing frequency from 1928; but from the nomination of Stephen A. Douglas (1860) to 1956, Harding (1920) was the only incumbent senator to win a major party presidential nomination. In 1960, however, Sen. John F. Kennedy became the nominee of the Democratic party and in 1964 Sen. Barry M. Goldwater became the Republican nominee.

Governors have long been highly important as aspirants for the nominations. Disregarding four presidential nominees who had succeeded to the presidency from the vice-presidency, 8 of the 20 first-time presidential nominees from 1896 to 1964 were incumbent governors. Three first-time nominees, Bryan, Davis and Willkie, held no governmental position at the time of their nomination; two, Taft and Hoover, were cabinet members; two, Parker and Hughes, were high court judges; three, Harding, Kennedy and Goldwater, were senators; one, Eisenhower, was a regular army general; and one, Nixon, was vice-president.

With so many sources from which candidates for the nominations may come, the conventions occupy a critical place in the career aspirations of the political and other leaders of the United States. The career development and preconvention campaign activities that lead up to the final decisions tend to involve all elements of the U.S. social order. The presidential nominating process, consisting of the never-ending actions and activities that take place in anticipation of future convention decisions, is one of the main organizing features of U.S. life and politics.

Preconvention Campaigns.—When an open nominating situation is in prospect in one party or the other, willing candidates may announce as early as October or November of the preceding year. Early candidates incur the hazards of the "front-runner," but the filing requirements for the presidential primary elections in several important states require action by December or January for a successful race in the primaries that follow.

Preconvention campaigning was dominated by the so-called presidential primary elections after World War II, although they were held in fewer than half of the states. Since 1904, when Wisconsin provided for the selection of convention delegates at a primary election, the states have experimented with such widely different systems that no easy summary is possible; but in most of these states the delegates to the national conventions are chosen in a public election at which the adherents of the respective parties may vote. The voters may also be given an opportunity, directly or indirectly, to express a preference among two or more of the candidates for a presidential nomination. The chronology of the presidential primaries in a typical presidential year begins with New Hampshire in March; includes Wisconsin, New Jersey, Pennsylvania and Massachusetts in April; the District of Columbia, Maryland, Indiana, Ohio, Alabama, West Virginia, Nebraska, Oregon and Florida in May; and California, Illinois, New York and South Dakota in June.

Something is usually known concerning the presidential candidate preferences of the would-be delegates, even in the states where there is no provision for putting such information on the ballot. In many of the primary states, would-be delegates can indicate their candidate preference on the ballot if the candidate gives consent; and in a few states, notably New Hampshire, Oregon and Florida, they can do so without the necessity of securing candidate consent. Generally when there is an active contest for the nomination of one party or the other, opposing presidential candidates of national stature can be expected to campaign vigorously in at least three or four of the presidential primary states. These state campaigns and elections usually attract national attention and clearly affect the estimates of the candidates that are held by the voters, as well as those held by the prospective delegates, even those from states where no primaries are held.

Time, Place, Composition.—The national conventions meet at a time and place previously determined by the respective party national committees. Formerly the conventions were usually held in June, but in 1952 and 1960 both were held in July, and in 1956 in August. In 1964 the Republican convention was held in mid-July and the Democratic convention late in August. There is no policy on which party meets first.

Chicago has been chosen as the convention city most frequently in the 20th century, with Philadelphia second. Baltimore was the favourite meeting place from 1832 to 1872. For most of a century, voting strength in both conventions was apportioned among the states in accordance with their electoral college vote, usually two convention votes for each of the state's senators and representatives in congress; and this was still a major factor in the apportionment in the 1960s. In preparation for its 1916 and later conventions, however, the Republican party adopted rules curtailing the representation of congressional districts (mainly in the south) where the Republican vote was light. Both parties later adopted the practice of giving "bonus" votes to the states carried by the party in a previous election, which had the effect of inflating total convention voting strength to more than 1,300 votes in each party by 1956. In Republican conventions, state delegations usually were restricted to their authorized size, with one vote for each

delegate; but the Democratic party repeatedly authorized the election of additional delegates on a half-vote basis and frequently seated delegates who held less than half a vote, with resultant confusion of voting procedures. In 1960, the Democratic party put all delegates on a half-vote basis and increased the total number of votes to 1,521.

Proceedings.—Each convention is opened by the chairman of the national party committee, and usually elects a temporary chairman on the first day. The temporary chairman may give the keynote address and usually presides until the organization of the convention has been completed. Senators have often served as temporary chairmen, but governors have done so increasingly in the 20th century. The permanent chairman usually takes over on the second or third day of the convention and presides during the adoption of the party platform and the balloting on presidential and vice-presidential nominations. During the 19th century, state and local party leaders usually served as permanent chairmen; in the 20th century the post was usually filled by an incumbent senator or representative in congress.

Party platforms are prepared in committees designated for the purpose. Platform issues have been hotly fought, with divided votes, in many Democratic conventions, including notably those of 1924 and 1948; but no platform issue came to a divided vote on the floor of a Republican convention from 1936 to 1960. There was, however, a Republican floor fight in 1964.

Nominations are the work of the convention as a whole and have not directly involved any prior committee action since 1840. Candidates are placed in nomination with eulogistic nominating and seconding speeches; noisy demonstrations are then staged by the supporters of each nominee parading up and down the aisles; and eventually the convention votes. The roll of the states is called alphabetically, and the vote of each state delegation is reported by its chairman; if necessary the delegation is polled. The state's vote may be divided among two or more candidates, unless the delegation is bound by its state to vote as a unit. Many contests are settled on the first or second ballot, but even in the 1940s and 1950s, several ballots were sometimes necessary. In rare instances, such as Franklin D. Roosevelt's nomination at the Democratic national convention of 1936 and Lyndon B. Johnson's nomination at the 1964 Democratic convention, a candidate is nominated by acclamation without the formality of a roll call vote.

Vice-presidential nominations follow the presidential. Frequently the vice-presidential choice has been determined by the presidential nominee in consultation with other party leaders, after which other candidates for the lesser nomination have withdrawn and the convention has ratified the choice without a contest. But in 1956, Stevenson followed the example of Bryan in 1896—an example that Bryan never again followed himself—in insisting that the convention itself make the choice. Sen. Estes Kefauver won the nomination on the second ballot.

Throughout the 19th century, the candidates usually remained at their homes while the conventions were in session; and committees were sent, often weeks later, to advise the successful candidates officially of the convention action. In the 20th century, willing candidates began to be present at the convention city oftener but rarely appeared in the convention itself before 1932. In that year, however, F. D. Roosevelt came to Chicago by airplane from Albany, N.Y., and appeared in person at the end of the Democratic convention to accept its nomination. After that time, major candidates were usually present in the convention city during the proceedings, and appearance of the nominees to make acceptance speeches at the final session became customary.

Reform Proposals.—Throughout their history, the conventions have been among the most criticized of political institutions, perhaps because they provide so many opportunities for the organization, manipulation and display of political power. Throughout the 20th century, a favourite reform proposal has been to replace the conventions with a national presidential primary, to be provided either by a constitutional amendment or by federal law encouraging uniform state action. Public reaction to the conventions of 1952, the first to receive full television coverage over nationwide networks, was interpreted by some observers as giving great impetus to the movement for a national presidential primary. But that impetus failed to show itself in congress, except in the adoption of a presidential primary law for the District of Columbia. State legislatures also were slow to register any notable desire to install primaries in states where they did not already exist.

At mid-20th century the conventions undoubtedly had become the object of a greater amount of professional and scientific research activity than at any previous time in their history. While such research mainly added to the store of knowledge concerning the complexities of the presidential nominating process, it also produced many suggestions for changes in procedures. It seemed that these might eventually have a significant cumulative effect without changing the fundamental nature of the convention institution, which seemed to be firmly established as a part of the U.S. political system.

NATIONAL COUNCIL OF CHURCHES. The National Council of the Churches of Christ in the U.S.A. was formed in December 1950 by a merger of 12 national interdenominational agencies, several of which had been organized as early as 1908. Its purpose is to provide an organization through which member churches can express their common faith and cooperate with one another on programs to which the bodies themselves consent or which they initiate. The council has no authority over its constituent bodies. Among its objectives and functions, as stated in its constitution, are to encourage fellowship and counsel concerning the spiritual life and religious activities of the churches; to promote cooperation among local churches and the development of state and local councils of churches; to encourage study of the Bible; to do for the churches such common services as are desired; and to provide a medium of consultation, research, and planning.

By 1967 there were 30 Protestant and Orthodox bodies constituent to the council, of which 24 were Protestant. Almost 40 other denominations or agencies of denominations cooperated in one or more of the council's programs. In the constituency of the council were approximately 144,000 local congregations with about 110,000 ministers. In these were over 40,000,000 members, of which more than 35,000,000 were Protestant. The council also cooperated with about 900 local and state councils of churches which were responsible to their own state and local churches.

The council carries out many of its activities through four divisions. The Division of Christian Life and Mission provides encouragement of study and action in international affairs; education among groups and individuals to apply Christian principles to economic life and racial and cultural relations; counsel and guidance to the ministries in hospitals and prisons; and coordination of activities in furtherance of religious liberty, social welfare, and stewardship. The division also maintains a consultation service on church building; administers a cooperative migrant ministry for seasonal farm workers; and encourages broad planning to meet the special needs of rural and urban churches and of home missions institutions. The Division of Overseas Ministries coordinates, counsels, and interprets the cooperative phases of the overseas work of participating foreign mission boards and denominations; supplies medical services to foreign missionaries; and conducts a literacy program in about 200 languages. The Division of Christian Education helps the churches to develop guidance materials for local work in religious education; gives leadership in the improvement of administration of Sunday school programs; and administers about 600 leadership schools annually. It encourages weekday

religious education and vacation schools and coordinates the educational work of the denominations with respect to church-related colleges.

The Division of Christian Unity, created in 1965, includes United Church Women, who participate in activities of local interdenominational councils of church women; encourage observance of the annual World Day of Prayer; and engage in varied programs in missions, family life, race relations, and civil liberties. United Church Men, also in this division, aid in the development of co-operative programs among local groups of laymen and encourage their interest in such subjects as missions and education.

Among other units of the council, the Department of Church World Service is a channel through which many denominations carry on a world-wide program of relief and rehabilitation to needy and suffering persons abroad, in most cases victims of natural disasters and political upheaval. It has administered services resulting in the resettlement of more than 115,000 refugees in the United States and has shipped overseas as much as 350,000,000 lb. of materials, mainly food, in one year. An activity of the Department of Evangelism is a cooperative ministry in the national parks that provides religious services to visitors. The Broadcasting and Film Department presents radio and television messages; develops films and film strips; and provides training for both clergymen and laymen on the use of radio and television. The Department of Research carries on various research projects; promotes research by other agencies; and maintains a centre of information on church statistics. It edits the *Yearbook of American Churches,* which presents official information from all faiths.

The General Assembly of the council (triennial) and the General Board (meeting between sessions of the assembly) on occasion issue policy statements. Among them are: the council stands opposed to racial segregation in the churches and community life; believes in and supports the right of both employers and employees to engage in collective bargaining; believes in and supports the procedures of the United Nations; advocates broad international trade and the foreign-aid program of the United States; is unalterably opposed to Communism and stands against its evils, violence, and violations of human rights.

The council's General Board consists both of clergymen (almost two-thirds) and lay persons, elected or appointed by the constituent bodies. On the committees supervising the program units lay people approximately equal clergymen in numbers. Of the council's net budget, more than half comes from church bodies; the remainder is made up of proceeds from sales of materials, gifts of individuals, foundations, and corporations, and proceeds from investments. Headquarters is in New York City.

NATIONAL DEBT: *see* DEBT, PUBLIC.

NATIONAL GEOGRAPHIC SOCIETY, a U.S. scientific society founded in Washington, D.C., in 1888, "for the increase and diffusion of geographic knowledge." From a small local organization founded by eminent explorers and scientists it had grown to become the largest scientific and educational society in the world, with an international membership of over 4,500,000 in the late 1960s. All members receive the society's monthly journal, the *National Geographic Magazine,* and many maps issued as supplements. Annual membership dues support all of the society's activities, which have included more than 200 major scientific projects and expeditions.

From the expeditions of Walter Wellman and Robert E. Peary to Richard E. Byrd and Paul A. Siple, the society has supported and encouraged arctic and antarctic exploration and published firsthand accounts of explorers. In the early 1930s its giant stratosphere balloons, launched jointly with the U.S. army air corps, pioneered in scientific exploration of the upper air and attained the greatest elevation reached by man up to that time (13.71 mi.). National Geographic expeditions, often cosponsored with the Smithsonian and other institutions, have studied volcanic eruptions and earthquakes, excavated Machu Picchu, lost city of the Incas on a Peruvian mountain top, and discovered in Mexico the oldest dated work of man in the new world.

The society helped explore and bring into the U.S. national park system such national treasures as the Valley of Ten Thousand Smokes in Alaska, Carlsbad caverns and Pueblo Bonito in New Mexico and the giant sequoias of California. In 1958 the society presented Russell cave, Alabama—in which was uncovered a record of 9,000 years of North American prehistory—to the national park service. (*See* also ALABAMA: *History.*) In 1949–56 the society and the California Institute of Technology, working with the Palomar observatory telescopes, produced for world distribution a *Sky Atlas* of unprecedented scope. More recent activities have included archaeological examination of the vast, long-forgotten capital of Maya civilization, Dzibilchaltun, in Yucatán, in co-operation with Tulane university, and anthropological research by Dr. and Mrs. L. S. B. Leakey in east Africa that has produced fossil remains of hominids of record antiquity.

Besides its expeditions, its magazine and its maps, the society fulfills the purpose for which it was organized through its school service which issues weekly bulletins to educators, librarians and students in the United States; a news service which issues daily releases on world events for press, radio and television; its illustrated books presenting scientific information in readily understandable form; globes, atlases, educational television; and occasional scientific monographs by its expedition leaders.

Melville Bell Grosvenor, son, grandson and great-grandson of presidents of the society, became its president and editor in 1957. *See* also GROSVENOR, GILBERT HOVEY.

See *National Geographic Magazine,* 75th Anniversary Issue (Jan. 1963). (M. B. G.)

NATIONAL GUARD, the name applied in the U.S. to a volunteer organization of individuals who devote part of each week to military training. Older than the nation, it has the longest history of any military organization in the U.S. Its origin goes back to the early 17th century when the colonists, to protect their lives and property, formed militia companies (*see* MILITIA). As the nation grew, the National Guard grew, and as towns sprang up and states were added to the union, additional guard units were formed for local and national protection.

Early History.—The oldest National Guard units in the U.S. with unbroken lineages are the 101st Engineer Battalion and the 182nd Infantry Regiment, Massachusetts National Guard. These units began Oct. 7, 1636, when the Boston general court ordered all military men in the area to form into militia regiments. Two of these, the north regiment and the east regiment, which fought in the Revolutionary War, later became the 182nd Infantry and the 101st Engineers.

Throughout the colonies, similar militia organizations were formed, and in 1775 the Committee of Safety of the second Continental Congress organized them into an overall defense force. These militia provided about 165,000 of the 396,000 troops raised for Washington's continental army. During the period 1776–90 specific militia laws were first passed by the states to regulate the militia and enroll all free males between certain ages as a proper, natural, and safe defense of a free state. These were based on the Declaration of Independence and the Articles of Confederation, which declared that a well-regulated militia was necessary but should not be superior to the civil power nor assume the role of a standing army in time of peace. From these laws arose the concept of a volunteer, state-supported national guard.

After independence, the principle of the citizen-soldier was considered so important by Washington and the first Congress that it was written into the Constitution. Section 8, article I empowered Congress to provide for calling forth the militia to execute the laws of the union, suppress insurrections and repel invasions, and for organizing, arming, and disciplining the militia; the states were to appoint officers and to train the militia according to the discipline prescribed by Congress. The second amendment to the Constitution (article II of the Bill of Rights) recognized the right of the citizen-soldier, in the interests of "a well-regulated militia," to keep and bear arms. Ultimately this basic authority resulted in the establishment of the present National Guard.

Although President Washington constantly pressed Congress to prepare "a uniform and well-digested plan" for the militia, no action was taken, and militia were separately formed and trained by each state. By the act of Feb. 28, 1795, Congress gave the president authority to call out the militia in cases of invasion and other emergency, but federal use of state militia depended on the individual state's acceptance of the president's request. A step toward a uniform militia and an eventual national guard was taken when Congress in 1808 provided for annual specific federal aid to support state militia, although they still remained under state control.

The name "national guard" was first applied to a state militia on Aug. 16, 1824, when New York's 7th regiment (now the 107th Infantry Regiment, New York National Guard), acting as an honour guard for the Marquis de Lafayette during his visit to the U.S., adopted the name in tribute to his Revolutionary War service and in honour of his command of the Garde Nationale in Paris in 1789. By 1896 most states had adopted the title, although the guard remained a state organization.

20th Century.—During the 19th century, the militia remained generally unwieldy and sprawling, although it played an important part in providing troops and units in four wars: 1812, Mexican, Civil, and Spanish-American. In 1903 Congress enacted laws whereby the federal government assumed a more direct and active part in organizing, training, and equipping the militia under the same standards as those prescribed for the regular army. With the enactment of the National Defense Act of June 3, 1916, the organized militia was officially recognized as the national guard and made to conform to regular army organization. As such, it became a component of the nation's organized peace establishment and, when called into active federal service, a part of the Army of the United States.

In 1916 approximately 151,000 guardsmen were called into federal service, of which 110,000 served on the Mexican border. During World War I the National Guard supplied more than 380,000 soldiers for the American Expeditionary Force. Seventeen guard divisions were sent overseas, of which 11 saw actual combat. Of the eight U.S. divisions rated excellent or superior by the German high command, six were National Guard divisions.

The general demobilization of units and the discharge of individuals from federal service after World War I made it necessary to rebuild the national defense force, including the National Guard. Under postwar amendments to the National Defense Act of 1916, the National Guard was reorganized to consist of the same guard divisions that had served during the war. This act, in setting forth a completely new military policy for the United States, established an "Army of the United States" which consisted of the regular army, the organized reserve corps, and the National Guard when called into federal service. The National Guard remained a state force under the command of state authorities. The new act also provided for increased federal assistance: when units reached certain minimum standards of strength, equipment, and skill, they were formally recognized as eligible for federal support.

The act of June 15, 1933, created a new component of the army known as the National Guard of the United States. This component, while identical in personnel and organization to the National Guard of the several states, was a part of the Army at all times and could be ordered into active federal service by the president whenever Congress declared a national emergency, without the necessity of being called through the governors of the states.

In August 1940 the president ordered the National Guard of the United States to active service. Between Sept. 16, 1940, and Oct. 1, 1941, the National Guard brought into service more than 300,000 men in 18 combat divisions and numerous nondivisional units, including 29 air observation squadrons. These troops immediately doubled the strength of the standing army. Guardsmen supplied trained leaders for the expanding army, with an estimated 82,000 enlisted guardsmen later becoming officers. Nine divisions went to Europe and Africa, and nine crossed the Pacific.

After World War II, National Guard units were demobilized and their personnel separated from federal service. Briefly there actually was no National Guard. On Oct. 13, 1945, the secretary of war approved the organization of the postwar National Guard, and on June 30, 1946, the first reorganized National Guard unit was federally recognized. In 1947 the air units of the National Guard were organized separately from the Army units and designated the Air National Guard. Since that time the National Guard has consisted of the Army National Guard and the Air National Guard. Since 1954 both have participated in the antiaircraft defense of the United States.

During the Korean War more than 183,000 guardsmen in 8 infantry divisions, 22 wings, and many other units were ordered into active federal service. Four divisions and 17 wings were stationed in the United States, 2 divisions and 3 wings served in Europe, and 2 divisions and 2 wings fought in Korea.

The National Guard continues to have a dual status and mission. Each federally recognized unit is simultaneously a part of the National Guard of its own state and of the National Guard of the United States. The function of the National Guard of the several states is to provide organizations in each state, so trained and equipped as to enable them to function efficiently to protect life and property and to preserve peace, order and public safety under the state authorities. The duty of the National Guard of the United States is to provide units of the reserve components of the Army and Air Force, adequately organized, trained, and equipped, available for mobilization in the event of war or national emergency, and capable of combat operations in support of war plans of the department of defense.

NATIONAL INCOME ACCOUNTING. The traditional purpose of national income studies is to furnish measures of the production of the nation. Beginning approximately with the 1930s, and quite explicitly since World War II, their purpose has come to be conceived more broadly as that of providing a systematic account of the economic activity of the nation. Inasmuch as production is a major feature of economic activity the two aims are closely interrelated.

National Output.—The terms "national output," "income," "product" and "expenditure" are often used interchangeably. National output, the term used in the following discussion, is the total of final or end products produced by the nation during a specified period. That is to say, it is the sum of products available for consumption or for additions to the stock of capital. Raw materials and semifinished products used up in production are not counted separately. For instance, if flour is baked into bread, only the bread is counted. National output is expressed in monetary values, since these provide a common unit for summing the wide variety of goods (commodities and services) produced.

The bulk of the production covered by measures of national output consists of items that are intended for sale in the market. Goods provided outside the market place are usually excluded, even though they may resemble items that are included by virtue of the market criterion. For instance, the services of housewives are usually excluded while services rendered by domestics are included. However, monetary values are generally imputed to wages paid in kind, to food and fuel produced on farms for home consumption, to the services which owner-occupants derive from their homes, and sometimes also to certain services, such as the handling of bank deposits, which financial institutions render free of charge to individuals. The treatment of nonmonetary items raises difficult problems in the measurement of the output of industrially undeveloped countries, where many types of productive activity that are channeled through the market in western countries are performed within the confines of the individual household.

The above explanation of national output has been in terms of product flows, because such an approach makes clear that the goal is to measure goods available for the satisfaction of human wants.

However, inasmuch as the production of goods gives rise to a simultaneous flow of incomes—wages, profits, etc.—national output may also be envisaged as a sum of income flows. In practice, national output measures are prepared both by summing product flows and by summing income flows.

The relationship between these two types of measures is basic to the understanding of the entire structure of national income statistics. Accordingly, a somewhat more exact explanation of it will be given by reference to the operations of a typical business enterprise. (The bulk of national output originates in such enterprises, although certain services—mainly those of household and government employees—also are counted as part of national output.)

The typical business enterprise produces goods which it either sells or adds to its inventories. Chargeable to this production are purchases of raw materials and other intermediate products from other enterprises (but not purchases of fixed plant and equipment); wages, salaries and other incomes paid out in production; indirect business taxes, such as sales, excise and property taxes; and depreciation and kindred allowances for fixed capital used up. A residual item of profit or loss equalizes the expenses chargeable to production with its value.

Expenses chargeable to production and profits	Production
Purchases of intermediate products	Sales
Wages and other incomes chargeable to production	Inventory change
Indirect taxes	
Capital consumption allowances	
Profits	

If a statement of this type is prepared for the business system as a whole, those sales of enterprises that represent purchases of intermediate products by other enterprises cancel one another. Thus purchases of intermediate products disappear from the left-hand side of the statement and sales on the right-hand side are correspondingly reduced. Matching the noncanceling final products there remains a numerically equivalent total consisting of income streams (including profits), indirect taxes and capital consumption allowances. (Inasmuch as the income aggregate reflects current production, capital gains and losses are not included.)

Variant Measures.—All measures of national output are net in the sense that intermediate products used up in production are not counted separately, but only as part of the value of the final products in which they are embodied. The definitions, however, vary significantly in other respects. Three points of differences may be noted.

1. Mainly because it is difficult to estimate how much fixed capital is used up in production during a given period, many national output measures are defined on a "gross" basis; *i.e.*, before deduction of capital consumption allowances. This definition is adopted even though in principle the using up of fixed capital is similar to that of intermediate goods. However, "net" measures allowing for the use of fixed capital are just as common, even though the allowances usually fall short of being meaningful from the standpoint of indicating the true net change in the capital stock.

2. Measures of national output are sometimes valued in terms of market prices and thus reflect indirect taxes, which are part of market price. Alternatively, national output may be defined net of these taxes (in technical terms, at factor prices or costs).

As is suggested by the previous demonstration of the equivalence of the product flow and income flow measures, net national output at factor prices is equivalent to the sum of incomes generated in production—wages and salaries, interest, rents and profits. These are measured before deduction of direct taxes—mainly taxes on individual or business earnings.

3. Measures of national output may refer to the output produced within the confines of a nation, or to the output to which residents of a nation have a claim. The two definitions differ because earnings derived from abroad provide residents of one nation with claims on output produced in others.

Differences between the gross and net and the market price and factor price measures are usually substantial. In the United States, for instance, the gross market price measure (gross national product) exceeds the net factor price measure (national income) by about one-fifth, with capital consumption allowances and indirect taxes contributing about equally to the spread. Differences between output measures due to variant treatments of international claims may also be significant.

It is necessary to distinguish between genuine output measures and various related aggregates that are not strictly measures of output. A widely used aggregate of the latter type (personal income, in the commonly accepted terminology) measures the sum of incomes received by individuals. Although the bulk of this aggregate arises in the production of national output, it cannot be regarded as a measure of the latter, since, on the one hand, it excludes some forms of income arising in production (such as undistributed profits) and, on the other, it includes incomes that do not reflect current productive activity (for instance, relief payments).

Adjustment for Price Change.—Measures of national output are usually expressed in terms of the prices current in the period to which the measures refer. Accordingly, changes over time in similarly defined output magnitudes reflect both changes in the quantity of goods produced and in the level of prices at which these goods are valued. For many purposes it is useful to have measures which separate the effect of the "real" (*i.e.*, quantity) change from that of the price change. They are obtained by expressing the goods produced in different time periods in terms of constant prices. These are usually the market prices that actually prevailed in one year, or in an average of years, during the period for which the measure is constructed. The approach to the comparison of real outputs produced in different countries is similar to that just outlined for time comparisons.

Output Breakdowns.—Measures of national output are usually accompanied by breakdowns of the totals that provide significant information on various aspects of the economy. The following are the breakdowns most frequently used.

1. The value of national output is shown in terms of the economic character of the products—essentially consumption and additions to capital stock, with further subdivisions of these two basic categories. It is also shown in the same statement in terms of the sales of these products to major purchaser groups, usually consumers, business enterprises, government and foreign nations. The exact manner in which the type-of-product and the type-of-purchaser classifications are reconciled is not uniform. The aggregate broken down in this way is usually valued at market prices.

2. The value of national output is shown in terms of the various types of incomes—wages and salaries, interest, rents and profits—originating in production. This classification is usually of the aggregate expressed net at factor prices. Sometimes, however, capital consumption allowances and indirect taxes are included, and a breakdown of the entire value of national output gross at market prices is thus provided.

3. The value of national output may be classified to show the portions of it originating in the various industries, such as agriculture, manufacturing and trade. This classification is generally given in terms of the income rather than the product flow measure. Industry breakdowns of output vary as regards the output definition (net or gross, market or factor price, etc.) that is used.

4. National output may be shown allocated to the various regions of a nation. To sidestep some of the special problems involved in such an allocation, the total is often not strictly a measure of national output, but the related aggregate of individual income receipts.

5. Some variant of this aggregate also most frequently underlies statements in which income is classified by the size of the unit income, the unit being usually the family or the single individual living separately. Such size distributions show the number of consumer units and the total income in successive income brackets.

System of Accounting.—It is apparent that the output breakdowns listed shed a great deal of light on the structure of the economy. However, the facets of the economy so illuminated remain separate, and no fully coherent picture of the whole in terms of its component parts emerges. The technique of national income accounting (social accounting, national accounting, etc.—terminology varies) has been designed to overcome this

shortcoming. It helps to envisage the precise relation to one another of the various facets of the economy on which information has been obtained, and it provides a framework for the actual preparation of coherent statistical pictures of the economy.

In essence, the economy is regarded as consisting of transactors, such as enterprises, households and governmental units, each such entity recording its transactions in a consistent set of accounts. For each transactor, three types of accounts are usually distinguished conforming to certain basic and distinct economic functions. The first account records its transactions as a producer —along the lines sketched above in the explanation of the equivalence between the product and income flow measures. The second shows its transactions as a recipient of net income (from its own production as well as from other sources) and as a consumer, and includes a residual item of saving. The third account summarizes its transactions as a saver and investor, showing the disposition of its total saving among financial and tangible investment. To show interrelationships clearly, each transaction would be identified twice in an ideal scheme. For instance, purchases made by one transactor unit in its capacity as consumer would be shown as sales of another unit in its capacity as producer.

Many problems are encountered in drawing up the specifications of this accounting scheme. Some of these arise because the basic types of accounts distinguished are not applicable to all types of transactors with equal ease. For instance, the essential features of the production account for enterprises can be envisaged by reference to the operating statement of a typical business firm. But there is no similar guide to set the pattern for the production accounts of households and governments, and experts are not unanimous in their choice among several alternatives.

As to the detail in which transactors might be classified, there is no limit in principle. In the extreme, the economy might be depicted in terms of a separate set of accounts for each transactor. In practice, information is insufficient to implement such a scheme; moreover, so detailed a picture would be of no use, because in it one would not see the forest for the trees. Accordingly, statistical pictures of the economy in terms of interrelated accounts are confined to broad consolidations of the ultimate detail. Essential information on aspects of the economy which these consolidations do not bring out is shown in supporting tables.

Many types of consolidations are possible; one deserves mention because closely related variants of it underlie the national income presentations of many countries. In this consolidation, the accounts showing the productive activities of enterprises and other economic transactors are summed to yield twin measures of the national output—one in terms of product flows, the other in terms of income flows. Accounts showing transactors as recipients of income—including transfers, such as relief payments and taxes —and as consumers of output are usually distinguished for two broad groups, households and government; a consolidated receipt and expenditure account is provided for each of these groups. (The corresponding accounts for enterprise transactors are often merged with the production accounts.) Next, the saving-investment accounts for all transactors are consolidated to show such an account for the nation as a whole. Finally, an external account is provided to show transactions with foreign countries.

This particular consolidation of the underlying accounting scheme is selected for statistical implementation for pragmatic reasons. It contains measures of total output, which is the focus of national income statistics; it shows explicitly the transactions of households and governments, and saving-investment transactions per se, which are important for understanding the functioning of the economy; and it suppresses distinctions that are of lesser significance or that cannot generally be quantified because statistical information is lacking.

Related Systems.—The term national income statistics is usually confined to the measures of national output and of its breakdowns, and to the summary descriptions of the economy that have been described. There are three bodies of statistical information, not covered by the conventional use of the term, that can be seen to be closely related to national income estimates if the national income accounting approach is adopted.

1. Interindustry relation (input-output) studies aim at a depiction of the economic process which focuses on product flows among industries. They provide a full accounting for these flows, including intermediate goods, which are excluded from conventional national income statistics because the latter are concerned with final output.

At a high level of abstraction which omits many detailed points of comparison that are of importance in the actual use of the data, the relationship of input-output to national income statistics may be grasped by reference to the detailed accounting scheme for individual units that has been shown to underlie the latter. Input-output tables can be regarded as an alternative manner of summarizing this scheme; in essence, transactors are grouped on an industry basis.

2. Moneyflow systems trace, in addition to the flows accounted for in national income statistics, financial transactions such as transfers of deposits and lending and borrowing. These are not reflected in conventional national income estimates because the latter provide only one consolidated saving-investment account for the nation as a whole in which domestic financial transactions cancel. These transactions could be introduced into national income statistics by providing separate saving-investment accounts for appropriate groups of transactors. Again, this is only a general sketch of the relationship between the two systems.

Input-output and moneyflow data have been developed less extensively than national income estimates narrowly defined, partly because they require additional primary statistical information that is difficult to obtain. The extent to which they have been integrated with the national income accounts varies from country to country.

3. Statistics of national wealth are usually distinguished from those of national income, but inasmuch as wealth is largely the result of saving and investment, which are part of the national income estimates, the close relationship between the two sets of figures is apparent.

Uses of National Income Statistics.—National income data are a tool for evaluating the performance of the economy, mainly in terms of the total amount and the composition of goods provided, and their distribution among various groups of the community. They are also an aid in understanding the functioning of the economy; *e.g.*, the nature of business fluctuations, the regularities in the distribution of income and the tendencies for long-term economic growth or retardation. They foster such understanding because they provide quantifications of many of the key magnitudes with which economic reasoning on these matters deals.

Among the practical uses of the data, those concerned with public policy have been most prominent. National income estimates have been used, for instance, in formulating policy recommendations relating to economic mobilization during war, to the stabilization of business activity and to economic reconstruction and development. Intelligent policy decisions in these and other matters involve the assessment of the probable course of future events. For instance, anti-inflationary measures are in order, not if inflation has prevailed in the past, but if it is believed that it will prevail in the future. National income categories have been used to furnish a set of concepts in terms of which the future is viewed, and the record of recent and past developments provided by the statistics has been studied to yield clues as to the probable course of future events.

The extent to which these economic forecasts have been elaborated has varied. Often policy recommendations have involved only implicit forecasts of selected aspects of the economy. Sometimes they have been based explicitly upon complete descriptions ("models") of the anticipated course of the economy as a whole. While the latter approach has not been more successful, it will be outlined because it exhibits some of the logic and limitations that characterize also the more eclectic variant.

In problems relating to wartime economic mobilization, for instance, the broad technique is to estimate the total national output that can be produced under given assumptions relating to the availability of labour and other resources and probable trends in productivity. This total is then allocated among the conflicting

military and civilian requirements. Next, the money demands for civilian output that would be generated at the projected level of national income are estimated. Finally, if these demands are found to differ from supplies at existing prices, the tax, monetary, allocation and other measures needed to bring them into equality at reasonably stable prices are determined.

The phase of this analysis that deals with the probable magnitude of private demands at the projected level of national income usually relies heavily on past regularities in economic behaviour, such as past relations between income and market demand. These relations are also used in gauging the effects on demand of tax measures, such as specified changes in tax rates. But relations that have obtained in the past are often modified in projecting the future, to take into account the expected effects of altered circumstances. Other techniques, such as surveys of spending intentions, can also be used to help in forecasting.

Similar techniques are applied to problems of peacetime stabilization. The demand for national output is forecast on the basis of foreseeable future developments. If this demand is found to deviate from a level of output that is satisfactory from the standpoint of the stabilization goal, the fiscal, monetary and other measures necessary to stimulate or restrict demand are gauged. Projection of past relationships and surveys of spending intentions are the mainstays of this analysis also.

Use of national income data in problems of economic reconstruction and development involves a similar confrontation of the projected national output with the demands upon it and adjustment of the two to each other by means of the policy actions available to the government. In many instances an analysis of the role of international trade, aid and investment is essential in working out a solution.

Even though national income statistics are used widely in formulating public policy recommendations, the precise nature and significance of their role is not clearly established. In only a few countries have the methods reviewed been used intensively even on a technical level. Moreover, the weight which policymakers have given to recommendations based on these methods has been limited by other considerations that influence practical policies, as well as by the admitted shortcomings of the methods themselves.

The conclusions these methods suggest are uncertain partly because national income data are subject to considerable error but mainly because our knowledge of the future behaviour of the economic system is imperfect. National income estimates provide only a record of past events, and there is no guarantee that the regularities disclosed will persist in the future. Nor will plans indicated in surveys of spending intentions necessarily materialize.

Nongovernmental uses of national income statistics also have become prominent. In particular, businessmen use the estimates to gauge the general economic climate in which their enterprises will operate. The over-all magnitudes embodied in these forecasts are used also to infer future market conditions for particular goods in which individual firms are interested, either as purchasers or sellers. These evaluations aid in the formulation of investment, production, price and other policies.

In addition to these and other applications, which have made national income statistics a widely used tool for practical orientation in the economic world, the data have been employed increasingly in academic studies, to test and develop hypotheses of economic theory. The problems encountered have to a large extent coincided with those confronted in the practical use of the data.

Sources and Methods of Compilation.—Existing programs of primary data collection are not designed specifically to measure national output, its components and the other entries in the national accounts. Instead, these magnitudes must be estimated by utilizing information prepared largely for other purposes. Prominent among this information are census enumerations and sample surveys, and statistics that are by-products of various governmental activities such as the administration of social security systems, tax laws and expenditure programs. Many other sources, too varied to summarize, are also used. The basic data often depart definitionally and in coverage from the items in the national income accounts. Estimation of these items involves, accordingly, the integration of all the available—and sometimes conflicting—information, and the filling of data gaps by resort to partial and indirect evidence.

National income figures are thus subject to error not only because of inaccuracies in the basic data but also because of imperfections in the estimating methods. Moreover, their margin of error cannot be precisely quantified, because the usual mathematical techniques for measuring error are not applicable to this complex case. Estimates of the margin of error which occasionally accompany national income figures fall short of definitional precision and incorporate a great deal of subjective judgment.

The reliability of national income statistics depends on the adequacy of the primary information and the effectiveness of the estimating techniques. It varies greatly from country to country, and within each country among the several entries in the accounts and according to the time period covered. Reliability is likely to be vastly higher for advanced industrial countries than for countries in which industrial processes have not developed. This situation is so mainly because industrial economies are characterized by transactions that lend themselves to registration in statistical form, and because the problems confronting such economies are likely to induce extensive data collection.

Other things being equal, relative errors in broad aggregates are likely to be smaller than those in its separately estimated components, because of offsetting error. For any given series, estimates referring to the remote past and to very recent periods are likely to be less accurate than estimates for intervening dates. This situation is so because the primary data diminish rapidly as one explores further into the past, and because estimates for recent periods are usually made before all the source material is at hand. Similarly, quarterly and monthly series are likely to be less accurate than annual estimates.

In an intensive use of the data it will be necessary to go beyond these generalizations and, mainly by an examination of the methodology underlying the estimates, form a judgment as to the order of their reliability. Thus, not only the preparation of national income statistics but also their use requires skill.

Availability of National Income Statistics.—National income estimates were prepared (in England) as early as the 17th century. But workmanlike estimates covering a span of years and built up from detailed components are largely a product of the 20th century. The economic problems associated with the depression of the 1930s and World War II made it vitally important to understand the economy and gave further impetus to the development of the statistics, largely under governmental aegis. In the postwar period, problems of economic reconstruction and development have had similar effects.

Originally indigenous to western industrial countries, national income estimates are now available for a large number of others, differing widely as to needs, resources technologies and institutional structure. The UN and other organizations have been active in promoting international comparability, both by developing standard accounting systems and by preparing compilations in which reported series are adjusted to uniform definitions.

Other noteworthy tendencies are the preparation of estimates on a less than annual basis and a speed-up in their publication schedules. This emphasis on recency reflects the active use of the data in current business analysis.

Unsettled Problems.—Following are some outstanding unsolved problems relating to the design of national income statistics.

1. As noted earlier, measures of national output are confined largely to output intended for sale, but marginal departures from this rule are made by imputing values to certain nonmarket items. These imputations are a source of irritation logically, because they do not flow from any general definition of output that can be specified. Moreover, the treatment of nonmarket production constitutes an acute practical problem in the analysis of economic conditions in countries whose market economies are undeveloped and also in international comparisons. Accordingly, much thought has been devoted to nonmarket output. Some progress has been

made through the proposal of international conventions for its treatment, and *ad hoc* solutions may be found to serve the needs of specific analyses. But it seems doubtful whether an operational definition of national output not anchored to the market criterion ever can be devised.

2. There has been a tendency to advance either market or factor price as the sole basis for valuing output, to the exclusion of the other method. On the whole, the market price valuation has gained in acceptance. It expresses goods in terms of the prices at which they are actually exchanged, and hence is the more realistic, easily understood and statistically convenient method.

The major justification of factor price series is that they are the best available measures of the services rendered by the ultimate agents of production, such as labour and capital, and that they provide a tool for the investigation of problems involving the allocation of these productive resources among alternative uses. Indirect business taxes must be excluded, it is maintained, because they do not reflect the services of productive agents as does the sum of wages, profits and other incomes originating in production.

The main objection to this argument is that it is based upon an assumption of circumstances—mainly stable and competitive business conditions—that do not obtain in practice. If these are absent, national output aggregates cannot be used to gauge resource allocation even if indirect taxes are excluded. For instance, the productive contribution of capital resources will not be reflected adequately in the national income totals in times of reduced economic activity when profits are depressed and in some instances even negative; similarly, monopolistic practices in an industry may give rise to incomes that give an exaggerated notion of the proportion of procedure resources actually engaged there.

3. Questions have been raised as to the proper distinction between final output and intermediate products. Specifically, it has been urged that not all of the output purchased by government be considered final, as is commonly done. Some of it should be excluded from the national output total, it is said, as are intermediate products. Somewhat more tentatively, it has been suggested that not all output bought by consumers be regarded as final either. No clear-cut proposals have been made, but the general idea appears to be to distinguish purchases that are direct causes of final human satisfaction from those that are only indirect conditions of it, and to exclude the latter. Opponents of the idea have argued that the proposed distinction cannot in fact be drawn; and they have not been refuted, either in logic or through the presentation of a viable classification that implements the proposed narrowing of the final product concept.

4. For some of the uses that are made of the data, it would be desirable to extend the definition of capital formation beyond its core, tangible capital formation by business, to intangible items, such as expenditures for industrial research, and to capital formation by government and consumers. Little has been done to recognize intangible capital, but capital expenditures by government have increasingly been taken into account, instead of being treated like current consumption.

The acquisition of residences is the only consumer purchase that is generally recognized as capital formation. There are sound reasons for extending this treatment to other consumer durables, inasmuch as these also outlast the normal accounting period and thus constitute additions to wealth. However, the extent to which capital accounting has been applied to them in actual national income estimates has been limited.

Measurement of capital formation on a gross basis, *i.e.*, before deduction of capital consumption allowances, raises problems because it is difficult to frame a uniform definition. For instance, it is hard to draw a systematic line which will either exclude or include repair and maintenance expenditures. In addition, the gross measure is insufficient because it does not show net additions to the capital stock. However, it appears difficult also to obtain a net capital formation measure that is meaningful for output measurement.

The conventional capital consumption allowances made by business are inadequate to serve as subtrahends from gross capital formation for this purpose. To an increasing extent they are affected and made noncomparable over time by changes in tax laws. In addition, they are usually stated in terms of the original cost of the capital goods, and hence cannot be deducted from gross capital formation, which is expressed in current prices, to obtain a meaningful indication of the net change in capital stock. The realism of the methods used to allocate capital consumption charges over the lifetime of the assets is also often in doubt. It is not easy, however, to devise alternative, more meaningful measures of capital consumption.

The task of offsetting capital equipment used up against capital equipment produced is made difficult by changes in the character of the equipment, and by inadequate knowledge of the actual life span of capital goods and the time pattern according to which they are consumed.

5. Difficulties (additional to those involved in the accounting for nonmarket production) are encountered in comparing outputs produced in situations that differ radically as to needs, resources, technologies and institutional organization. These difficulties arise because in these circumstances the composition and the types of goods produced are likely to be very different. If, for instance, output of commodity A in one country is double that in another while output of commodity B is one-half, it is not possible to make an unambiguous comparison of the outputs of A and B combined. The result depends on the relative value that is attached to each commodity. Again, if in one time period output of transportation equipment consists of horse-drawn carriages, and in another of automobiles, it is not really possible to make a quantitative comparison between the two. As long as differences in composition and kind are moderate, the methods for calculating real national output described earlier will yield useful results. But little significance attaches to the precise outcome of comparisons when these differences are substantial.

6. Apart from problems involving the definition of output, many others have arisen concerning accounting design: what are the economic groups whose activities should be separately shown? What types of accounts should be established? How should the transactions registered in the accounts be classified? What part of the information should be presented in interrelated accounts, and what part in supporting tables? While many of these issues are largely presentational, some have broader significance. For instance, the finances of unincorporated business are usually intermingled with the household finances of their owners, and one of the important problems of accounting design is to find a satisfactory place for unincorporated enterprise among business and household transactors. *See* also references under "National Income Accounting" in the Index.

BIBLIOGRAPHY.—International Association for Research in Income and Wealth, *Bibliography on Income and Wealth* (1952–54), covers the period beginning 1937 and includes references to earlier bibliographies. Contributions to the national income field can often be found in works mainly devoted to related disciplines; *e.g.*, A. C. Pigou, *The Economics of Welfare* (1924). A. L. Bowley, C. Clark, S. Kuznets and J. R. N. Stone have made outstanding contributions specifically to the development of national income statistics. J. R. Hicks, *The Social Framework* (1952), and R. and N. D. Ruggles, *National Income Accounts and Income Analysis*, 2nd ed. (1956), are introductions. The Statistical Office of the United Nations publishes international compilations of national income data. I. Ohlsson, *On National Accounting* (1953), is a comprehensive treatise. *A System of National Accounts and Supporting Tables*, United Nations Statistical Office (1953), is a proposal for a uniform system of national income accounts. M. Gilbert and I. B. Kravis, *An International Comparison of National Products and the International Purchasing Power of Currencies* (1954), considers basic problems of international income comparisons. *National Income, 1954 edition*, National Income Division, U.S. Department of Commerce (1954), describes the theoretical framework and statistical methodology of the United States estimates. *National Income Statistics, Sources and Methods*, Central Statistical Office (1956), is a similar statement for the United Kingdom. *Personal Income by States Since 1929*, National Income Division, U.S. Department of Commerce (1956), contains a discussion of the methodology underlying regional estimates. Income size distributions are considered in *Income Distribution in the United States, By Size, 1944–1950*, National Income Division, U.S. Department of Commerce (1953); S. Kuznets, *Shares of Upper Income Groups in Income and Saving* (1953); and T. Barna, *The Redistribution of Incomes through Public Finance in 1937* (1946). The Conference on Research in Income and Wealth and the International Association for Research in Income and Wealth each publish a

continuing series, *Studies in Income and Wealth* and *Income and Wealth*, respectively. Vol. 22 of *Studies* contains a comprehensive discussion of theoretical problems. (G. Jr.)

NATIONALISM, a state of mind in which the supreme loyalty of the individual is felt to be due to the nation-state. Though attachments to the native soil, to parental traditions and to established territorial authorities have been known throughout history, it was only at the end of the 18th century that nationalism began to become a generally recognized sentiment molding public and private life and one of the great, if not the greatest, single determining factors of history. Thus nationalism is a modern movement, but, in the short span of its existence as a dominant element of societal life and organization, it has shown such a dynamic vitality and such an all-pervading character that the mistake has frequently been made of regarding nationalism as a permanent, or at least very ancient, factor of history. In reality nationalism arose as a dominant force in the 18th century in western Europe and in North America; the American and the French revolutions may be regarded as its first powerful manifestations. From the western world, after having penetrated the new countries of Latin America, it spread in the early 19th century to central Europe; thence, toward the middle of the century, to eastern and southeastern Europe, until, at the beginning of the 20th century, it put its stamp on the ancient lands of Asia and Africa. Thus nationalism has become a dominating force everywhere—so much so that the 19th century has been called "the age of nationalism" in Europe, while the 20th century has witnessed the rise and struggle of national movements throughout Asia and Africa.

Nationalism implies the identification of the state or nation with the people, or at least the desirability of determining the extent of the state according to ethnographic principles. In the age of nationalism, but only in the age of nationalism, the principle was generally recognized that each nationality should form a state—its state—and that the state should include the whole nationality. Formerly states, or territories under one administration, were not delineated by nationality; men's loyalty was not due to the nation-state, but to other, different forms of political organization: the city-state, the feudal fief and its lord, the dynastic state, the religious group or the sect. The nation-state was nonexistent during the greater part of history and for a very long time it was not even regarded as an ideal. In the first 15 centuries of the Christian era the ideal was the universal world-state, not loyalty to any separate political entity. The Roman empire had set the great example which survived not only in the Holy Roman empire of the middle ages, but also in the *res publica christiana* (Christian republic or community) and in its later secularized form of a united world civilization and world policy as it appeared in the writings of the 17th century.

As political allegiance, before the age of nationalism, was not determined by nationality, so civilization was not thought of as nationally determined. During the middle ages civilization was looked upon as determined religiously; for all the different nationalities of Christendom as well as for those of Islam there was but one civilization—Christian or Muslim—and but one language of culture—Latin (or Greek) or Arabic (or Persian). Later, in the periods of the Renaissance and of classicism, it was the ancient Greek and Roman civilizations which became a universal norm, valid for all peoples and all times. Still later French civilization was accepted throughout Europe as a valid civilization for educated people of all nationalities. It was only at the end of the 18th century that, for the first time, civilization was considered to be determined by nationality and the principle was put forward that a man can be educated only in his own mother tongue, not in languages of other civilizations and other times, be they classical languages or the literary creations of other peoples who had reached a high degree of civilization. From the end of the 18th century on, the nationalization of education and public life went hand in hand with the nationalization of states and political loyalties. In many cases poets and scholars emphasized cultural nationalism first. They reformed the national language, elevated it to the rank of a literary language and delved deep into the national past, thus preparing the foundations for the political claims for national statehood soon to be raised by people in whom they had kindled the spirit of nationalism.

National feeling was evident in certain groups at certain periods, especially periods of stress and conflict, before the 18th century. Its rise was prepared by a number of complex events: the creation of large, centralized states by the absolute monarchs, who destroyed the feudal allegiances and thus made possible the integration of all loyalties in one centre; the secularization of life and education which fostered the development of the vernacular languages and weakened the ties of religious or sectarian loyalties; the growing economic interdependence which demanded larger territorial units, which would at the same time give the necessary scope to the dynamic spirit of the rising middle classes and their capitalistic enterprise. This large, unified territorial state with its political and economic centralization was filled in the 18th century with a new spirit—an emotional fervour similar to that which in preceding periods characterized religious movements. Under the influence of the new theories of the sovereignty of the people and the rights of man, the people replaced the king as the centre of the nation. No longer was he the nation or the state; the state had become the people's state, a national state, a fatherland. Nation and state became identified, as civilization became identified with national civilization.

This was opposed to all the conceptions which had dominated political thought for the preceding 2,000 years. During that period man had commonly stressed the general and the universal and had seen in unity the desirable goal. Nationalism stressed the particular and parochial, the differences and the national individualities. These tendencies became more pronounced as nationalism developed. In the 17th and 18th centuries the common standards of western civilization, the regard for the universally human, the faith in reason—one and the same everywhere—and in common sense, the survival of Christian and Stoic traditions were too strong to allow nationalism to develop fully and to disrupt society. Thus nationalism in its beginning was thought compatible with cosmopolitan convictions and with a general love of mankind, especially in western Europe and North America.

England.—The first full manifestation of modern nationalism occurred in 17th-century England, in the Puritan revolution. That century saw England the leading nation in the scientific spirit, in commercial enterprise, in political thought and activity. Swelled by an immense confidence in the new age, the English people felt upon their shoulders the mission of history, a sense that they were builders of destiny at a great turning point from which a new true reformation and a new liberty would start. In the English revolution an optimistic humanism and Calvinist ethics merged; the influence of the Old Testament gave form to the new nationalism by identifying the English people with ancient Israel. The new message, carried by the new people not only for England, but for all mankind, was expressed in the writings of John Milton in whose famous vision the idea of liberty was seen spreading from Britain, "celebrated for endless ages as a soil most genial to the growth of liberty" to all the corners of the earth. "Surrounded by congregated multitudes, I now imagine that I behold the nations of the earth recovering that liberty which they so long had lost; and that the people of this island are disseminating the blessings of civilization and freedom among cities, kingdoms and nations."

English nationalism was thus much nearer to its religious matrix than later nationalism which rose after secularization had made greater progress. The nationalism of the 18th century shared with it, however, the enthusiasm for liberty, the humanitarian character, the emphasis upon the individual and his rights and upon the human community beyond all national divisions. The rise of English nationalism coincided with the rise of the English trading middle classes. It found its final expression in Locke's political philosophy and it was in that form that it influenced American and French nationalism in the following century.

British North America.—The rising nationalism of the British settlers was influenced partly by the traditions of the Puritan revolution and of Locke, and partly by the new rational interpretation given to English liberty by contemporary French

philosophers. American nationalism became the typical product of the 18th century. The American settlers became a nation engaged in a fight for liberty and individual rights, basing that fight on current political thought, especially as expressed by Thomas Jefferson and Thomas Paine. This was a liberal and humanitarian nationalism, regarding America as the vanguard of mankind on its march to greater liberty, equality and happiness for all. The ideas of the 18th century found their first political realization in the Declaration of Independence and in the birth of the American nation. Their deep influence was felt in the French Revolution.

France.—Rousseau had prepared the soil for the growth of nationalism by his stress on popular sovereignty and the general co-operation of all in forming the national will, and also by his regard for the common people as the true depository of civilization. Under his influence Herder gained a new understanding of art and civilization by emphasizing folklore, folk songs and primitive popular traditions as revealing the true creative forces of a nation. He went beyond Rousseau in his appeal to the past—often to the primitive past. He glorified the instinctive and irrational, and turned attention from the universally human and general to the peculiarities of each national tradition, regarding them as valuable sources of creative inspiration. Under Herder's influence German romantic nationalism later stressed these factors of irrationalism and of national peculiarities.

The nationalism of the French Revolution, on the other hand, was the triumphant expression of a rational faith in common humanity and liberal progress. The famous slogan "liberty, equality, fraternity" and the Declaration of the Rights of Man and of the Citizen were thought valid not only for the French people, but for all peoples. Individual liberty, human equality, fraternity of all peoples: these were the common cornerstones of all liberal and democratic nationalism. In their name the French nation constituted itself, overthrew the monarchy and soon began to spread the new gospel across Europe. Under their inspiration a new ritual was developed which partly took the place of the old religious ritual: festivals and flags, music and poetry, national holidays and patriotic sermons. In the most varied forms nationalism permeated all manifestations of life. Like the rise of American nationalism, the rise of the French produced a new phenomenon in the art of warfare: the nation in arms. In America and in France, citizen armies, untrained but filled with a new fervour, proved superior to professional armies which, though highly trained, fought without the incentive of nationalism. The revolutionary French nationalism stressed free individual decision—in the formation of nations. Nations were constituted by an act of self-determination of their members. The plebiscite became the instrument whereby the will of the nation was expressed. In America as well as in revolutionary France, nationalism meant the adherence to a universal progressive idea, looking toward a common future of freedom and equality, not toward a past characterized by authoritarianism and inequality.

Germany and Other Countries.—Napoleon's armies spread this nationalism throughout Europe and even into the near east; across the Atlantic it aroused the Latin Americans. But Napoleon's yoke turned the nationalism of the Europeans against France. In Germany, where the struggle was led by writers and intellectuals, it turned into a rejection of all the principles upon which the American and the French revolutions had been based and of the liberal and humanitarian form of nationalism. German nationalism began to stress instinct against reason; the power of historical tradition against rational attempts at progress and a more just order; the historical differences between nations against their common aspirations. The French Revolution, liberalism and equality were regarded as a brief aberration, against which the eternal foundations of societal order would prevail.

This interpretation was shown to be false by the developments of the 19th century. Liberal nationalism reasserted itself; it permeated more and more peoples: the rising middle class and the new proletariat. The revolutionary wave of 1848, the year of "the spring of the peoples," seemed to realize the hopes of nationalists such as Mazzini, who had devoted his life to the unification of the Italian nation by democratic means and to the brotherhood of all free nations. Though his immediate hopes were disappointed, the 12 years from 1859 to 1871 brought the unification of Italy and Rumania, both with the help of Napoleon III, and of Germany; at the same time the 1860s saw everywhere great progress in liberalism, even in Russia and Spain. This victorious trend of liberal nationalism was, however, reversed in Germany by Bismarck. He unified Germany on a conservative and authoritarian basis and defeated German liberalism. The annexation of Alsace-Lorraine against the will of the inhabitants was contrary to the principle of nationalism based upon the free will of man. The people of Alsace-Lorraine were held to be German by objective factors, by race, independent of their will or of their allegiance to any nationality of their choice.

In the second half of the 19th century nationalism disintegrated the supranational states of the Habsburgs and the Ottoman sultans, both of which were based upon prenational loyalties. In Russia the penetration of nationalism provoked a twofold attitude: some nationalists advocated an acculturation of Russia to the general progress of western mankind. They proposed a westernized Russia, following the common destiny of progressive society. Others stressed the distinctive character of Russia, its independent and different destiny, based upon its past of autocracy and orthodoxy. These Slavophiles, similar to and influenced by German romantic thinkers, saw Russia as a future saviour of a west undermined by liberalism and the heritage of the American and French revolutions. As a result of World War I, nationalism triumphed in central and eastern Europe. The new nation-states, Austria, Hungary, Czechoslovakia, Poland, Yugoslavia, the U.S.S.R., as well as Rumania, emerging from the ruins of the Habsburg and Romanov empires were, however, subject themselves to the strains of internal nationality conflicts and territorial disputes with neighbouring states.

Lenin's triumph in Russia in 1917 meant the triumph of international communism over Russian nationalism. Fascism and National Socialism in Italy and Germany in the 1930s presented an unprecedented intensification of an authoritarian nationalism. In their turn they influenced the older totalitarian movement of communism. In World War II the communist leaders tried to use nationalism for their own purposes. After the war, the new nations created after World War I came under communism; but nationalism in these communist-controlled countries rebelled against the claim of centralized leadership throughout the communist world. With Tito setting an example in Yugoslavia, this so-called national communism became important and helped inspire the liberation movements in Poland and Hungary in the fall of 1956, and to bring about the consequent shift away from centralized communism.

Asia and Africa.—World War I stirred the masses in Asia to inaugurate their age of nationalism under the leadership of such powerful personalities as Kemal Atatürk in Turkey, Saad Zaghlul in Egypt, Ibn Saud in the Arabian peninsula, Gandhi in India, and Sun Yat-sen in China. Atatürk succeeded in replacing the medieval structure of the Islamic monarchy with a revitalized and modernized secular republic in 1923. The demands of Arab unity were frustrated in Africa and Asia by British imperialism and in Africa by French imperialism. Yet Britain showed a gift for accommodation with the new forces by helping to create an independent Egypt (1922; completely, 1936) and Iraq (1932), and displayed a similar spirit in India, where the Indian National Congress, founded in 1885 to promote a liberal nationalism inspired by the British model, had become more radical after 1918. In China Sun Yat-sen pleaded before his death (1925) for China's cooperation with communist Russia. Only Japan, influenced by Germany, used modern industrial techniques to strengthen a more authoritarian nationalism.

After World War I, the League of Nations, organized as the first major institution to attempt to internationalize an attack on war, embodied in its governing principles the progress to independence through nationalism as being in accord with the best traditions of western liberalism. The treaty of Versailles, in addition to providing for the constitution of the League, had reduced the empires of the losing Central Powers, mainly Germany and Turkey, by dispersing their African colonies as mandatories to England, France,

Belgium and South Africa, and their Pacific possessions to Japan, Great Britain, Australia and New Zealand, under classifications varying in their expectations of independence. The United Nations continued this plan after 1945 in its trusteeship system (*see* further MANDATE and TRUSTEESHIP SYSTEM).

The end of World War II saw for the first time a period in history in which the political attitude of nationalism was the greatest determining force. The swell of nationalism was especially notable throughout Asia and for the first time in Africa. The League of Nations numbered among its original members five Asian countries (China, India, Japan, Thailand and Iran) and two African countries (Liberia and the Union of South Africa, later the Republic of South Africa) and had added only three Asian countries (Afghanistan, Iraq and Turkey) and two African countries (Egypt and Ethiopia) before its dissolution in 1945. Of the mandated territories under the League's control only Iraq, Lebanon and Syria achieved independence during its lifetime. Of the original 51 members of the United Nations in 1945, eight were Asian (China, India, Iraq, Iran, Lebanon, Saudi Arabia, Syria and Turkey) and four were African (the same as in the League). Less than a quarter of a century after the founding of the United Nations, 66 member nations had been added, 55 of them being Asian and African. Whereas Asian and African nations had never totaled a third of the membership in the League, they came to represent nearly half of the United Nations. Of these new Asian and African nations, four in Asia and seven in Africa were in part or in whole created from mandated territories.

The emergence of the United States and the U.S.S.R. as dominant world powers, both inside and outside the United Nations, and the prospect of nuclear war stimulated the new nationalism. India, Pakistan, Ceylon, Burma, Malaya in Asia, and Ghana in Africa achieved independence peacefully from the British Commonwealth, and the Philippines from the United States. Others had to fight hard for their independence in bitter colonial wars, as in French Indochina (Vietnam, Laos, Cambodia) and French North Africa (Tunisia, Algeria). From the beginning communism had appealed to the new nationalist movements in Asia and Africa, first for support in their struggle against western capitalism, and later after independence was achieved in competition with western capitalism for financial and technical aid. Chinese nationalism under Chiang Kai-shek during World War II was reduced with the take-over of the Chinese communists, but after Khrushchev's announcement of the "de-Stalinization" process in 1956, Chinese communism began to drift away from supranational communism, as the European communist countries had earlier, until in the late 1960s Russian and Chinese mutual recriminations of "revisionism" barely concealed a Chinese nationalism in which Mao had risen beside Lenin in the place of honour. As Chinese communism turned farther and farther inward, its influence on newborn Asian and African nations apparently waned.

Ambitions among new Asian and African nations clashed as they had earlier in Europe. Disputes and situations in the United Nations illustrated the problems of the new nationalism: the struggle with Netherlands colonialism for the establishment of Indonesia, continuing in the case of West Irian (West New Guinea) into the late 1960s; the Suez crisis in 1956, with the intervention of UN forces between those of Egypt and Israel; continuing troubles in the middle east ranging from the establishment of Israel to inter-Arab state disputes brought on by the establishment of the United Arab Republic; the India-Pakistan dispute over Jammu and Kashmir; the Korean partition and subsequent war; the four-year intervention in the Congo; the struggle of Greece and Turkey over the newly independent Cyprus; Indonesian and Philippine objection to the inclusion of Sarawak and Sabah (North Borneo) in the newly formed Federation of Malaysia.

Many new nations, all sharing the same pride in independence, faced difficulties. As a result of inadequate preparation for self-rule, the first five years of independence in the Democratic Republic of the Congo passed with no semblance of a stable government. The problem of varying peoples and languages was exemplified in the Federation of Nigeria, where an uncounted population including an uncounted number of tribes (at least 150, with three major divisions) used an uncounted number of languages that included at least a hundred languages and dialect clusters. Religious differences kept the question of whether the predominantly Muslim state of Jammu and Kashmir should go with Muslim Pakistan or Hindu India alive for nearly 20 years after the India Independence act became effective in 1947. Desperate economic competition caused trouble, as in Israel where the needed life-giving water of Jordan kept it in constant dispute with its water-hungry Arab neighbours.

Meanwhile in Europe after World War II, the spirit of nationalism first waned with the establishment of NATO and the common market schemes, but later the leadership of De Gaulle, claiming to speak as a spokesman not only for France but for Europe, and the resurgence of West Germany indicated a revival of nationalism.

NATIONALITY. As a legal concept, nationality is distinguishable from the popular use of the term to denote membership in a nation, meaning a people bound together by ethnic, religious, or linguistic ties. (*See* NATIONALISM.) It is also distinguishable from citizenship (*q.v.*), a somewhat narrower term that is sometimes used to denote the status of those nationals who have full political privileges. Before an act of the U.S. Congress made them citizens in the full sense of the word, for example, American Indians were sometimes referred to as "noncitizen nationals."

Not only individual human beings but also companies (corporations), ships, and aircraft have nationality for the purposes of law. It is in reference to natural persons, however, that the term finds most frequent use. In general, nationality implies the duty of allegiance on the part of the person and the duty of protection on the part of the state. The UN Universal Declaration of Human Rights (*see* CIVIL LIBERTIES) in 1948 stated that "everyone has the right to a nationality" and that "no one shall be arbitrarily deprived of his nationality. . . ." Whether an individual possesses the nationality of a particular state may determine whether or not that state has a right to exercise jurisdiction over him in certain circumstances. If he is a national he may enjoy political and economic rights and privileges that he would not otherwise have. How one acquires nationality, how it may be lost, the possibility of statelessness, and applications of the concept in international legal relations are matters of some practical importance.

The concept of nationality is found in both international law and national law. It is the nation-state which sets the criteria, through constitutional or statutory provisions, for determining who shall be its nationals. The right of a state to confer its nationality is, however, not unlimited, for otherwise it might impinge upon other states' rights to determine what persons shall be their nationals. By the *jus soli*, a person who is born within a state's territory and subject to its jurisdiction acquires that state's nationality by the fact of such birth. By the *jus sanguinis*, a person has a nationality as an inheritance from one or both of his parents. States vary in their use of these two principles. Some give priority to the *jus soli* but also rely to some extent on the *jus sanguinis*; others apply principally the *jus sanguinis*, but not all of these exclude the *jus soli*. When one state cedes terri-

tory to another, inhabitants of the region that is ceded commonly have an opportunity to acquire that state's nationality. Practice, however, supports the idea that the individuals concerned should be allowed a free choice, with the understanding that those who choose to retain their old nationality may have to leave the territory. Another method of acquiring nationality is through the process of naturalization (*see* NATURALIZATION LAWS).

An individual may lose his nationality through extinction of the state of which he has been a national. He may also lose it through naturalization in another state, but there is no universally binding law which requires that a state must recognize that one of its nationals, by reason of his being naturalized in a foreign state, has divested himself of his former nationality. There have been some treaties committing each signatory to recognize that its nationals who have migrated to the territory of another signatory and become naturalized there shall be regarded as having divested themselves of their original nationality.

The right of expatriation has not been universally recognized, however, and the possibility of dual or multiple nationality remains. Nor has the effort to eliminate statelessness been completely successful, although such an objective was considered by the League of Nations in 1930 and by the International Law Commission of the UN. Under U.S. legislation of the 1950s, loss of nationality may be the result of treason, desertion from the armed forces, evasion of the military draft, service in the army of a foreign state, or voting in an election in a foreign state.

In the late 1940s there was a move in the British Commonwealth to continue, through parallel legislation, a common status of British subject or commonwealth citizen, while each of the states retained its own citizenship. (*See* COMMONWEALTH OF NATIONS: *Nationality and Citizenship.*) Such common status as resulted did not rest indefinitely upon a common allegiance, as some of the states concerned adopted the republican form of government.

One problem that has been dealt with in national legislation and in a projected international agreement is that of the nationality of married women. The trend has been away from the practice that allowed a woman's nationality to be changed by the mere fact of her marriage or by a change in her husband's nationality. The UN General Assembly in 1957 approved a Convention on Nationality of Married Women. This convention embodied the rule that a woman's nationality is not to be automatically changed by virtue of a change in marital status.

In international law nationality assumes significance in various circumstances. In extradition treaties, states have often included clauses making it optional for them to surrender persons who are their own nationals. If a state desires to expel a person from its territory only the state of which the person is a national is obligated to receive him. A state's failure to afford reasonable protection to aliens may lead to claims by other states, the adjudication of which will require decision of questions concerning the nationality of claimants. Legal questions may also arise in connection with legislation affecting enemy aliens. Such persons may seek to avoid disabilities by becoming naturalized in a third state, but such efforts are not always successful.

(R. R. WN.)

NATIONALIZATION is one of a number of ways in which the state can alter or terminate the control or ownership of private property. Generally, in mature systems of law, the state or local government authorities possess the right to take private property for particular public purposes, such as the construction of roads, reservoirs or hospitals. In 1254 a power of this nature was granted by charter to the city of Copenhagen. Other examples may be found in the middle ages in German and Scandinavian law. The same principle was acknowledged in the French Declaration of the Rights of Man in 1789, as it was also in the fifth amendment to the constitution of the United States. The exercise of this right, which is normally accompanied by the payment of compensation, may be described as "expropriation" or as "eminent domain" (*q.v.*). By contrast, "nationalization" is historically a more recent development and differs both in motive and degree from "expropriation."

Nationalization is customarily, though not exclusively, associated with the implementation of communist or socialist theories of government. This is certainly true both of the transfer of industrial, banking and insurance enterprises to the state in Russia in the period after the acquisition of power by the Soviet regime in 1918 and of similar developments in Bulgaria, Czechoslovakia, Hungary, Poland, Rumania and Yugoslavia after World War II. The same may be said also of the nationalization of the coal, electricity, gas and transport industries in the United Kingdom and France between 1945 and 1950. However, the conscious implementation of political and economic doctrine has on occasion become mixed with resentment at foreign control over industries upon which the state may be largely dependent. This was clearly a factor in the nationalization of the oil industries in Mexico in 1938 and in Iran in 1951, in the nationalization of the Suez Canal company in Egypt in 1956 and in the nationalization of foreign businesses in Cuba in 1960.

The process of nationalization may take various forms: the assets of the nationalized companies are transferred to the state; or the share capital is made the object of the transfer, leaving the company in existence to carry on its business under state control. In any event, the result is ultimately that title to or control over the property is placed in the state itself or in a state-established and publicly controlled organ.

Questions of international law normally arise only when the property is owned either by aliens or by companies in which aliens have a large shareholding interest. It has become established as a matter of general principle that aliens carrying on activities or owning property in foreign states are entitled to treatment in accordance with a "minimum standard of international law." In particular, the arbitrary treatment of aliens is unlawful, as is discriminatory treatment directed toward them solely because they are aliens. In addition, as a result of a number of diplomatic episodes and international arbitrations, it is acknowledged, at least in relation to isolated takings of private property, that such taking is lawful only if accompanied by the payment of fair compensation. There are two leading decisions on this point. In the case of the Norwegian ships (*Norway* v. *United States*, 1925), the Permanent Court of Arbitration held that the United States was under an obligation to pay to Norwegian nationals, whose rights under certain shipbuilding contracts had been seized by the United States during World War I, a sum described as "fair compensation" for the loss which they had suffered. In assessing the amount payable, the court took into consideration such factors as the value of the contracts as between a willing buyer and a willing seller on the date of the seizure, the sum which the Norwegian nationals had actually expended and the amount of interest due if payment in respect of the seizures had been promptly made. The second case, that of the *Chorzów factory*, between Poland and Germany, decided by the Permanent Court of International Justice in 1927 and 1928, arose out of the seizure by the Polish authorities of certain German property in breach of the terms of the treaty of Versailles and of the Geneva convention of 1922. The case is notable for the distinction drawn by the court between lawful takings of alien property, for which fair compensation should be paid, and unlawful takings, for which not mere compensation, but true damages, should be paid. In this case the taking was unlawful because it involved a breach of a treaty; the judgment also may be interpreted that a taking may be unlawful if no genuine attempt is made to assess or pay fair compensation. A further important feature of the judgment is that it identifies "fair compensation" with "the value of the undertaking at the moment of dispossession, plus interest to the day of payment," and thus establishes an objectively ascertainable standard of fair compensation.

It remains a matter of controversy whether these authorities apply with equal force when the scale of the taking of alien property is expanded from isolated expropriation to large-scale nationalization. On the one hand, emphasis is placed upon the continuing

rights of the foreign investor. It is argued that these rights remain unaffected by any difference in degree between expropriation and nationalization; that there is no reason why the foreign investor should bear the cost of implementing local political policies; and that the alien suffers equal material loss in both cases. The right to nationalize alien property is, for these reasons, said to be conditional upon the payment of "prompt, adequate and effective compensation." On the other hand, stress is laid upon the sovereign right of every state to determine its own political, social and economic future. If need or theory require that the ownership of property should be vested in the state, its freedom of action should not be fettered by the fact that it is too poor to pay the fair market price for alien property. The foreign investor, it is argued, places his capital abroad in the hope of making profits, and he would not do so if he did not consider that the returns outweighed the risks. This contention is frequently coupled with the assertion that in many cases the value of the original investment of the alien had been fully returned to him in profits repatriated during the period of operation.

No international tribunal has yet been placed in a position to express an authoritative view on the controversy. The suggestion has been made that in case of true nationalization the solution lies in the payment of "partial compensation." It is doubtful, however, whether this formula is either sufficiently precise or adequately supported by authority for it to be accepted as representing existing law; though, admittedly, in practice, many disputes have been settled by agreement for amounts which have fallen short of the real value of the property involved. When the British claims against Mexico for expropriation of oil properties were settled in 1947, the compensation probably did not amount to more than one-third of the value of the property seized. Nor was any higher standard of compensation achieved by the "lump sum" agreements relating to the nationalization measures of the eastern European states after World War II. Although this method of settlement normally leads to the certain payment of at least a proportion of the true value of the property, it has been estimated, for example, that under the agreements between the United Kingdom and Yugoslavia and Czechoslovakia the original owners received respectively no more than 45% and 25% of their claims. In the case of the Suez Canal company, the Egyptian government agreed in 1958 to pay to the company a sum of £E28,300,000 over a period of six years and to allow the company to retain all its assets situated outside Egypt.

However, despite the apparent generality of the practice of settling nationalization disputes by agreements providing for compensation which is less than the full value of the property nationalized, there does not appear to be sufficient warrant for the view that customary international law now acknowledges the validity of nationalizations not accompanied by the payment of fair compensation. There is equally no adequate justification for the view that, because a number of states have nationalized foreign companies in breach of express undertakings to permit their operation for a fixed period of years, there is no rule of international law which protects specific contractual commitments. Nevertheless, as a means of reducing difficulties arising out of the uncertain content of the rules of customary international law relating to compensation, states whose nationals tend to be investors are placing increasing reliance upon specific treaty clauses providing for the protection of investments. The United States, in particular, has since the end of World War II entered into treaties of friendship, commerce and navigation which contain mutual undertakings on this point, coupled with clauses conferring compulsory jurisdiction upon the International Court of Justice.

For socialist and communist attitudes toward nationalization *see* COLLECTIVISM; COMMUNISM; SOCIALISM. *See* also references under "Nationalization" in the Index.

NATIONAL PARKS AND NATURE RESERVES. For hundreds if not thousands of years and in many countries man has given some sort of protection to those wild animals he has used for food and sport. Before the 19th century he seldom had any other motives; it is only relatively recently that animals have been thought worthy of preservation for their own sakes and for the appreciation of future generations of mankind. Even more recently has man begun to realize that it is not only the so-called game animals that need to be preserved, but the forests, the water and the soil itself—in fact, the whole natural scene.

Whatever the motives for preservation, the means must nearly always include setting aside areas where restraints are enforced. Such restraints may be permanent or restricted to certain months of the year; they may give protection to all creatures or to one class only (for example, birds) or even to one particular species, or they may impose restrictions upon the use of certain natural resources, such as timber. The area may be tiny or very large, privately owned or in government hands.

Because there are so many kinds of areas of preservation and because they have been coming into being in many countries at the same time, it is hardly surprising that there has been little uniformity of terminology. A national park in the United States or Canada is intended to safeguard natural features and wildlife in a way that will contribute to public enjoyment. National parks in England and Wales are thinly inhabited regions where the natural scenery is safeguarded; animal and bird life in Britain is preserved in nature reserves. In Africa, generally, the chief purpose of a national park is the preservation of wildlife. A game reserve may be a place where a stock of game for shooting is maintained by game management or it may be a larger area designed to preserve wildlife that is rapidly disappearing elsewhere. Even within a single country where the legal status implied by a name is usually clear, the actual effect of restrictions may vary from being highly effective to being worse than useless. A game reserve that is small in area may be invaluable because it protects a rare species and is properly guarded; another enormous area without guards and with only nominal restrictions may be a happy hunting ground for lawbreakers. In some countries, also, the local people have not learned the economic and tourist potential in their wild animals and slaughter them indiscriminately, either for meat or for portions of the carcass, or destroy the essential habitat by overgrazing of domestic livestock or by using the lands for crops.

The paradox of national parks is that whereas they may depend on tourists for their existence by creating public interest in wildlife preservation, the animals themselves depend for their preservation on being unmolested. The best way of resolving this paradox would seem to be to restrict the movement of the visitor, as has been done in numerous parks, by setting aside an area within or near the national park where hotels, restaurants, parking places for cars, etc., can be provided, and by locating a limited number of roads within the park. A constructive partnership must, in fact, be established between those responsible for tourism and those responsible for the preservation of the natural features the park was established to safeguard.

In a comprehensive article such as this it is not possible to distinguish between the effectiveness of areas of preservation nominally enjoying the same status, a fact that should be kept in mind in using the tables in this article. (These tables are derived from source materials from individual countries, *Derniers Refuges, Atlas Commente des Réserves Naturelles dans le Monde*, published in 1956 by the International Union for the Conservation of Nature and Natural Resources, and parts i and ii of the United Nations' *List of National Parks and Equivalent Reserves*, 1961 and 1962. Permission to use them is gratefully acknowledged.)

This article is divided into the following main sections:

I. United States
II. Canada
III. Africa
IV. Asia
V. Great Britain
VI. Europe
VII. Australasia
VIII. Central and South America

For bird and game protection and the protection of sea mammals and fish *see* WILDLIFE CONSERVATION.

I. UNITED STATES

The United States was long notoriously wasteful with its resources. In the brief span of three centuries verdant forests of vast regions were leveled, cover was torn from its soil, wildlife was pillaged and countless other offenses were committed against the natural fertility of the land. Fortunately, steps were taken early to prevent the exhaustion of natural resources. One early move in this direction was the transfer to the state of California, in 1864, of the Yosemite valley and the Mariposa grove of *Sequoia gigantea;* they were added to Yosemite National park in 1906. The concept of national parks under federal ownership originated in 1870, when the Doane-Washburn expedition investigated reports of the wonders of the Yellowstone. After some discussion of developing this region under the homestead laws, the matter was resolved when a member of the expedition, Cornelius Hedges, proposed that it should be the possession of all the people. Members of the expedition drafted legislation to that end, creating Yellowstone National park, and it was signed by Pres. Ulysses S. Grant in 1872. Eighteen years passed before Yosemite, Sequoia and General Grant national parks were established in 1890. During this time the idea of protecting outstanding scenic and scientific resources, wildlife and vegetation, for their own sakes, and to ensure perpetuation of the aboriginal attributes of the American scene grew into a concept of national policy.

The national park system was expanded during the following decades, not only with the addition of vast natural areas, but also with the inclusion of places of especial significance in the human history of exploration of the continent and the development of American Indian culture. At mid-20th century the system administered 176 areas comprising about 21,800,000 ac. and by the late 1960s about 220 areas embracing more than 26,500,000 ac.

Much of this land was originally part of the public domain, as was almost all of the land acquired by the new republic, beginning with western lands ceded by 7 of the original 13 states and continuing with later acquisitions such as the Louisiana Purchase. (For the disposition of this vast amount of territory *see* LAND TENURE: ECONOMIC AND AGRARIAN ASPECTS: *The United States;* and LAND SYSTEM [U.S.].) From these public lands were reserved the national forests, most of the national park system and many other reservations. However, large tracts have been donated to the national park system by some of the states and some gifts have been made by individuals.

Kinds of Protected Areas.—National parks are established by congress; another act of congress is required to change boundaries or to modify the basic protection, unless boundary adjustment provisions were specifically stated in the original act. National parks have been defined as spacious land and water areas of nationwide interest established as inviolate sanctuaries for the permanent preservation of scenery, wilderness, and natural vegetation and animal life in their natural condition.

National monuments are established by specific acts of congress or under the Antiquities act of 1906 which authorizes the president to reserve, by proclamation, federal lands for the protection of objects of historic, prehistoric and scientific interest: the latter provision enables the president to act without delay to safeguard assets in danger of despoilment. Jurisdiction over national monuments was originally in the hands of several different federal agencies, but in 1933 it was consolidated under the national park service.

Of the national monuments, about a third protect natural areas of scientific importance. Among the largest, Katmai, in Alaska, contains active volcanoes and the Valley of Ten Thousand Smokes as well as extensive forested habitat of several species of bears and other wildlife; Glacier Bay National monument (*q.v.*), also in Alaska, contains some of the most impressive active tidewater glaciers on the continent, high mountains and abundant wildlife; Death valley (*q.v.*) in California-Nevada contains outstanding sonoran desert ecology.

Other monuments, ranging from a square mile to several hundred thousand acres, are notable for their canyons, caverns, natural arches and other geological features, or for botanical exhibits such as succulent cactus, Joshua trees, coastal redwoods, etc. Some have been established especially to safeguard particular species of wildlife. Remains of aboriginal Indian cultures are preserved in about 20 national monuments; most of these are in the southwestern states but some are in other parts of the country. The remaining national monuments relate to the history of the continent after the coming of the white man. Places notable in the colonial and Revolutionary and American Civil War periods in the east, sites made famous in the settling of the west and landmarks in the careers of the nation's leaders are preserved and restored.

The national park service also administers national historical parks, military parks, battlefield parks and sites, and memorials commemorating principal engagements of the French and Indian War, the American Revolution and Civil War, and historic residences and sites not included in the system of national monuments. The value of this kind of preservation may be seen, for example, in the village of Appomattox Court House in Virginia, where Gen. Robert E. Lee surrendered to Gen. U. S. Grant on April 9, 1865, thus effectively terminating the Civil War. The village was at that time the seat of Appomattox county; later, when the county seat was moved elsewhere, it fell into decay and was in danger of total disappearance when its establishment as a national historical monument was authorized in 1935. It was thus established in 1940 and became a national historical park in 1954. It encompasses 972 ac.; the Wilmer McLean house, where the surrender took place, was restored, as were some other buildings.

Among other types of areas are national parkways, including the Blue Ridge parkway (to be 469 mi.), following the Appalachian ridges between Shenandoah and Great Smoky Mountains national parks; the Natchez Trace parkway, to follow the old Indian trail for 450 mi. between Nashville, Tenn., and Natchez, Miss.; and the George Washington Memorial parkway in Maryland and Virginia, 49 mi. when completed. Also included in the system are Civil War cemeteries; national seashores; national lakeshores; the Theodore Roosevelt National Memorial park in North Dakota; and the national capital parks in the District of Columbia, Maryland and Virginia. Public use of large reclamation reservoirs is administered (as recreation areas) by the park service. Among them are Lake Mead in Arizona and Nevada; Coulee Dam in Washington state; Glen Canyon in Arizona and Utah; Shadow Mountain in Colorado; Amistad in Texas; Arbuckle in Oklahoma; Bighorn in Wyoming and Montana; Curecanti in Colorado; Flaming Gorge in Utah and Wyoming; Sanford in Texas; and Whiskeytown-Shasta-Trinity in California.

Administration of the National Park System.—The national park service was established by an act of congress on Aug. 25, 1916, to administer the assigned areas "by such means and measures as conform to the fundamental purpose of said parks, monuments and reservations, which purpose is to conserve the scenery and the natural and historic objects and the wildlife therein and to provide for the enjoyment of the same in such manner and by such means as will leave them unimpaired for the enjoyment of future generations." This directive protects the national park system (a generic term that includes all the areas the park service administers except reservoirs) from exploitation for profit or from any development that would contravene the primary objective, that of preserving natural or historical features.

Park service policy, based on this act and augmented by more detailed formulations issued by the secretary of the interior and the service itself, is applied equally to all the categories in the system, with minor adjustments that recognize their varied charac-

TABLE I.—*A Partial List of Areas Administered by the United States National Park Service*

Name and location	Total gross acreage	Date established	Principal features
National Parks			
Acadia (Maine)	41,634	Part as Sieur de Monts National monument, 1916, and Lafayette National park, 1919; named Acadia, Jan. 19, 1929	Mount Desert Island and adjacent Atlantic coastal headlands; forests, mountains; seabirds
Big Bend (Texas)	708,221	June 12, 1944	Great bend of Rio Grande river; desert and mountain scenery; sonoran wildlife and botany
Bryce Canyon (Utah)	36,010	National monument, 1923; national park, Sept. 15, 1928	Vast eroded amphitheatres on Paunsaugunt plateau, with brilliantly coloured spires, pinnacles and walls
Canyonlands (Utah)	257,640	Sept. 12, 1964	Great wilderness area surrounding the confluence of the Green and Colorado rivers; colourful mesozoic canyons and spectacular land sculpture
Carlsbad Caverns (New Mexico)	46,786	National monument, 1923; national park, May 14, 1930	World's largest limestone caverns; calcite formations; bats; sonoran desert ecology
Crater Lake (Oregon)	160,290	May 22, 1902	Azure caldera 20 sq.mi. in area, with multicoloured walls 500 to 2,000 ft. high; conifer forests, alpine tundra, abundant wildlife
Everglades (Florida)	1,400,533	June 20, 1947	Subtropical wilderness grassland prairies, with mangroves, cypress and other plants; breeding colonies of egrets, herons, ibises, etc.; manatees; includes most of Florida bay
Glacier (Montana)	1,013,129	May 11, 1910	Glaciated Rocky mountain peaks, glaciers, lakes, forests, wildlife. Forms part of Waterton-Glacier International Peace park, established 1932
Grand Canyon (Arizona)	673,575	National monument, 1908; national park, Feb. 26, 1919	Upper half of 217-mi. gorge of Colorado river, 4 to 8 mi. wide, about 1 mi. deep; tremendous pediments, mesas and buttes carved in multicoloured rocks dating from Archean to Mesozoic eras; sonoran and montane ecology
Grand Teton (Wyoming)	310,350	Feb. 26, 1929; most of Jackson Hole National monument added 1950	Isolated glaciated Teton range with peaks to 13,766 ft.; broad open basin in foreground; conifer forests; winter feeding ground of largest American elk herd; moose, trumpeter swan, other wildlife
Great Smoky Mountains (North Carolina-Tenn.)	512,674	June 15, 1934	Appalachian ranges; primeval hardwood forests; wildlife
Guadalupe Mountains (Texas)	77,500	Oct. 15, 1966	Limestone uplift, caves; represents four climatic life zones; deer, elk, black bears, bighorn sheep, small mammals; prehistoric Indian ruins
Haleakala (Hawaii)	26,403	July 1, 1961	Haleakala volcano on Maui; endemic plants; products of volcanic activity
Hawaii Volcanoes (Hawaii)	220,345	National park including Haleakala, 1916; separate unit, July 1, 1961	Mauna Loa and Kilauea active volcanoes on island of Hawaii; tree fern forests with rare endemic plants and wildlife
Hot Springs (Arkansas)	1,032	Federal reservation, 1832; national park, March 4, 1921	Hot mineral springs and baths; characteristic Ozark woodland
Isle Royale (Michigan)	539,347	April 3, 1940	Forested island in Lake Superior; moose and other wildlife
Kings Canyon (California)	454,713	General Grant National park, 1890; enlarged as Kings Canyon National park, March 4, 1940	Canyons of Kings river and crest of Sierra Nevada range; General Grant grove of *Sequoia gigantea*
National Parks (Cont.)			
Lassen Volcanic (California)	106,934	Part as national monument, 1907; national park, Aug. 9, 1916	Lassen peak is the only recently active volcano in continental U.S. outside of Alaska; geologic, botanic and wildlife features
Mammoth Cave (Kentucky)	51,354	July 1, 1941	Limestone cave, 150 mi. of passages explored, with limestone, gypsum and cave onyx formations; underground rivers and lakes
Mesa Verde (Colorado)	52,074	June 29, 1906	Protects prehistoric Basket Maker and Pueblo Indian pit houses and finest cliff dwellings in the U.S.; Rocky mountain ecology
Mount McKinley (Alaska)	1,939,493	Feb. 26, 1917	Highest peak in North America, glaciers in Alaska range; arctic tundra; caribou, Dall sheep, wolf, bear, other wildlife
Mount Rainier (Washington)	241,983	March 2, 1899	Spectacular ancient volcano, with glaciers; dense forests, meadows, wildlife
Olympic (Washington)	896,599	Mount Olympus National monument, 1909; enlarged as national park, June 29, 1938	Wilderness of peaks, glaciers and rain forests; Roosevelt elk (subspecies of the wapiti); headlands and beaches along Pacific ocean
Petrified Forest (Arizona)	94,189	National monument, 1906; national park, Dec. 9, 1962	Extensive exhibit of petrified wood, Indian ruins and part of colourful Painted desert
Platt (Oklahoma)	912	Sulphur Springs reservation, 1902; national park, June 29, 1906	Cold mineral springs; prairie ecology
Rocky Mountain (Colorado)	262,324	Jan. 26, 1915	Front ranges of Rocky mountains, with 107 named peaks in excess of 10,000 ft.; conifer forests, alpine tundra, abundant wildlife
Sequoia (California)	386,863	Sept. 25, 1890	Groves of *Sequoia gigantea;* adjacent to Kings Canyon National park and administered jointly with it
Shenandoah (Virginia)	212,304	Dec. 26, 1935	Blue Ridge of Appalachian mountains with hardwood forests and wildflowers. Skyline drive traverses crest, continuing south as Blue Ridge parkway to connect with Great Smoky Mountains National park
Virgin Islands (Virgin Islands)	15,150	Dec. 1, 1956	Caribbean island, with green hills, beaches, tropical plants and animals; historic relics of Carib Indians and colonial sugar plantations
Wind Cave (South Dakota)	28,059	Jan. 9, 1903	Limestone caverns in Black Hills; conifer forests, open prairies; bison, antelope, prairie dog, other wildlife
Yellowstone (Wyoming-Montana-Idaho)	2,221,773	March 1, 1872	World's largest geyser area; canyons, falls, lakes, mountains; abundant wildlife of many species
Yosemite (California)	760,951	Oct. 1, 1890	Spectacular peaks, canyons, waterfalls in Sierra Nevada range; three groves of giant sequoias; dense forests; alpine tundra; wildlife
Zion (Utah)	147,035	Mukuntuweap National monument, 1909; named Zion National monument, 1918; national park, Nov. 19, 1919	Colourful tertiary canyons and mesas in high desert region
National Monuments			
A. Natural Areas			
Arches (Utah)	34,010	April 12, 1929	Eroded arches, pinnacles, in desert

TABLE I.—*A Partial List of Areas Administered by the United States National Park Service (Continued)*

Name and location	Total gross acreage	Date established	Principal features
A. Natural Areas (Cont.)			
Badlands (South Dakota)	111,530	Jan. 25, 1939	Eroded sedimentary badlands; fossils; short-grass prairie ecology
Black Canyon of the Gunnison (Colorado)	13,683	March 2, 1933	Sheer-walled canyon in San Juan mountains
Buck Island Reef (Virgin Islands)	850	Dec. 28, 1961	Coral reefs and undersea formations; marine gardens
Capitol Reef (Utah)	39,173	Aug. 2, 1937	Colourful sedimentary sandstone cliffs dissected by a narrow gorge along Fremont river
Capulin Mountain (New Mexico)	775	Aug. 9, 1916	Asymmetrical extinct volcanic cinder cone
Cedar Breaks (Utah)	6,155	Aug. 22, 1933	Vast natural amphitheatre eroded into variegated Pink cliffs 2,000 ft. thick; wild flowers
Channel Islands (California)	18,167	April 26, 1938	Santa Barbara and Anacapa Islands (1,120-ac. land area) offshore from southern California, to protect sea lion and seabird rookeries
Chiricahua (Arizona)	10,646	April 18, 1924	Tertiary rhyolitic monoliths and other geological features; arid mountains, desert and montane ecology with Mexican affinities
Colorado (Colorado)	17,362	May 24, 1911	Canyons, monoliths, in arid mesa region, bison
Craters of the Moon (Idaho)	53,545	May 2, 1924	Volcanic geology
Death Valley (California-Nevada)	1,907,760	Feb. 11, 1933	Desert wilderness; geological, botanical, faunal features; pioneer history
Devil's Postpile (California)	798	July 6, 1911	Basaltic lava columns rising as high as 60 ft.
Devils Tower (Wyoming)	1,347	Sept 24, 1906	865-ft exposed volcanic intrusion
Dinosaur (Utah-Colorado)	206,234	Oct. 4, 1915	Spectacular canyons of Green and Yampa rivers; dinosaur fossils
Glacier Bay (Alaska)	2,274,595	Feb. 26, 1925	Large tidewater glaciers, fjords; postglacial forests; abundant wildlife, especially bears
Grand Canyon (Arizona)	198,280	Dec. 22, 1932	Lower Grand canyon, including inner gorge
Great Sand Dunes (Colorado)	36,740	March 17, 1932	Shifting aeolian dunes at foot of Sangre de Cristo mountains; among the largest and highest dunes in U.S.
Jewel Cave (South Dakota)	1,275	Feb. 7, 1908	Limestone caverns with calcite encrustations
Joshua Tree (California)	557,992	Aug. 10, 1936	Stands of Joshua tree; sonoran desert ecology
Katmai (Alaska)	2,697,590	Sept. 24, 1918	Active volcanoes; Valley of Ten Thousand Smokes; subarctic conifer forests; Alaskan brown bear and other wildlife
Lava Beds (California)	46,239	Nov. 21, 1925	Volcanic geology; semi-arid mountain ecology; site of Modoc Indian war of 1873
Lehman Caves (Nevada)	640	Jan. 24, 1922	Ornamented limestone cavern in isolated Snake range
Muir Woods (California)	503	Jan. 9, 1908	Virgin stand of coastal redwood (*Sequoia sempervirens*)
Natural Bridges (Utah)	7,600	April 16, 1908	Three natural bridges, the highest 222 ft. above stream bed, with span of 261 ft.
Oregon Caves (Oregon)	480	July 12, 1909	Limestone caverns, with Jeffrey pine forest on surface
Organ Pipe Cactus (Arizona)	330,874	April 13, 1937	Sonoran desert plants and wildlife
Pinnacles (California)	14,498	Jan. 16, 1908	Volcanic and other geological features, with spire formations 500 to 1,200 ft. high
Rainbow Bridge (Utah)	160	May 30, 1910	Largest, most beautiful natural arch known, in Escalante desert, 309 ft. over stream bed
Saguaro (Arizona)	78,644	March 1, 1933	Saguaro forest and other succulent cacti
Sunset Crater (Arizona)	3,040	May 26, 1930	Volcanic cinder cone with summit crater formed just prior to A.D. 1100
Timpanogos Cave (Utah)	250	Oct. 14, 1922	Colourful limestone cave on Mt. Timpanogos
White Sands (New Mexico)	146,535	Jan. 18, 1933	Gypsum dunes 10 to 45 ft. high; wildlife
B. Archaeological Areas			
Aztec Ruins (New Mexico)	27	Jan. 24, 1923	Excavated 12th-century Indian town
Bandelier (New Mexico)	29,661	Feb. 11, 1916	Prehistoric Indian homes of later Pueblo period
Canyon de Chelly (Arizona)	83,840	April 1, 1931	More than 400 cliff dwellings dating as early as A.D. 1066, in magnificent canyon on Navajo reservation
Casa Grande Ruins (Arizona)	473	Reserved 1892; national monument, Aug. 3, 1918	Unique adobe tower probably built by Salado Indians in the 1300s in earlier Hohokam settlement
Chaco Canyon (New Mexico)	21,509	March 11, 1907	13 major Indian ruins; many smaller ruins
Effigy Mounds (Iowa)	1,468	Oct. 25, 1949	Large Indian mounds in shapes of birds and other animals
El Morro (New Mexico)	1,279	Dec. 8, 1906	Prehistoric petroglyphs, inscription in rock by explorers
Gila Cliff Dwellings (New Mexico)	533	Nov. 16, 1907	Cliff dwellings in centre of Gila Wilderness area
Grand Portage (Minnesota)	770	Historic site, 1951, national monument, Jan. 27, 1960	Principal canoe portage route of Indians, explorers and missionaries
Hovenweep (Utah-Colorado)	505	March 2, 1923	Unique towers built in 12th century
Montezuma Castle (Arizona)	842	Dec. 8, 1906	Outstanding cliff dwelling dating from about A.D. 1100
Mound City Group (Ohio)	68	March 2, 1923	24 ceremonial burial mounds of Hopewell people, dating from about A.D. 1000
Navajo (Arizona)	360	March 20, 1909	Three of largest known cliff dwellings, dating from 13th century
Ocmulgee (Georgia)	683	Dec. 23, 1936	Mounds built by farming Indians, dating from 10th century
Pipestone (Minnesota)	283	Aug. 25, 1937	Quarry from which Indians obtained materials for peace pipes
Russell cave (Alabama)	310	May 11, 1961	Cave containing record of human habitation from 6000 B.C. to A.D. 1650
Tonto (Arizona)	1,120	Dec. 19, 1907	Salado Indian cliff dwellings, in Salt river valley, dating from about A.D. 1350
Tuzigoot (Arizona)	43	July 25, 1939	Pueblo containing 110 rooms, which flourished between A.D. 1000 and A.D. 1400
Walnut Canyon (Arizona)	1,879	Nov. 30, 1915	200 small cliff dwellings, dating from A.D. 1000 to A.D. 1200
Wupatki (Arizona)	35,545	Dec. 9, 1924	Pueblos built by several tribes about A.D. 1100; desert ecology

Some other units of national park system protecting natural features

Name and location	Total gross acreage	Date established	Principal features
Theodore Roosevelt National Memorial park (North Dakota)	70,435	April 25, 1947	Badlands along Little Missouri river, with abundant wildlife
National Capital parks (District of Columbia-Virginia-Maryland)	37,406		Park system of the nation's capital, comprising 785 units
Assateague Island National Seashore (Md.-Va.)	39,630	Sept. 21, 1965	Island is a 35-mi. barrier beach parallel to Atlantic coast
Cape Hatteras National Seashore (N.C.)	28,500	June 12, 1953	Atlantic coastal beach; migratory waterfowl
Cape Cod National Seashore (Mass.)	44,600	Authorized, Aug. 7, 1961	Atlantic coastal beach; migratory waterfowl
Fire Island National Seashore (New York)	19,311	Sept. 11, 1964	Dunes, marshes, beaches; coastal wildlife
Indiana Dunes National Lakeshore (Indiana)	6,539	Nov. 5, 1966	Sand dunes and marsh on Lake Michigan shore
Point Reyes National Seashore (Calif.)	53,000	Authorized, Sept. 13, 1962	Pacific coastal beach
Padre Island National Seashore (Texas)	137,241	Authorized, Sept. 28, 1962	Flat, sparsely vegetated beachland on Gulf of Mexico
Pictured Rocks National Lakeshore (Michigan)	65,000	Oct. 15, 1966	Scenic reserve of multi-coloured rocks on shore of Lake Superior; forest

ters. Placing first emphasis on protection, with public use and enjoyment an essential corollary part of the objective, this concept of park administration has been adopted by many nations which later established national park systems of their own.

The system possesses natural resources attractive to interests that might profit from their exploitation, and from the beginning there have been repeated attempts to induce congress to weaken the rigid legal protection given one area or another. Yellowstone, Yosemite, Kings Canyon, Glacier, Grand Canyon and other areas include canyons where construction of hydroelectric or reclamation dams has been vigorously resisted; national controversies have raged over legislation that would have permitted Yellowstone lake to be dammed, Echo park in Dinosaur National monument to be flooded and other similar projects. Frequent efforts have been made to open individual parks and monuments, and even all of them, to mining; except within four areas (Mt. McKinley National park and Glacier Bay, Death Valley and Organ Pipe Cactus national monuments) in which mining is subject to regulation by the secretary of the interior, and a small section of Katmai National monument, mining was prohibited in the system.

On the principle that the native species should follow their natural behaviour patterns insofar as possible, hunting of all wildlife, including predators, is prohibited. In a few instances this policy, together with the fact that the aboriginal wildlife habitat lying beyond the park boundaries has been developed for human economic reasons, has resulted in overpopulations of certain large mammals so that the carrying capacity of the park ranges has been endangered, and the secretary of the interior has authority to reduce such species when scientific evidence demonstrates the need.

The most notable case is that of the wapiti in Yellowstone, where thousands of these elk share insufficient ranges with bison, deer, bighorn sheep and antelope. Proposals to open the park to public hunting were rejected as violating the fundamental objective, and a program of elk reduction by deputized hunters in parts of nearby Grand Teton National park proved ineffectual. Grazing of livestock is considered an activity not conforming to the purpose of the parks, but occasionally there are demands that the grasslands in the system be made available to domestic animals. Grazing privileges in effect at the time lands are brought under the park service are continued only through the lifetime of the permittee's immediate heirs, and grazing is gradually being reduced.

Overdevelopment, imperiling the assets the parks were established to safeguard, is probably the most difficult problem now confronting the administrating agency. Earlier, when most of the areas were remote and transportation slow and expensive, it was necessary to advertise them to arouse public interest in the national park program. Hotels and lodges were built in the parks, roads were provided to serve the infant tourist movement and dude ranching was developed. During the depression of the 1930s the modest appropriations provided by congress were supplemented by hundreds of millions of dollars in emergency relief funds and Civilian Conservation corps enrollees aided in keeping the parks in condition. World War II reduced the annual appropriations to as little as $5,000,000 and terminated emergency funds, but during that period relatively few tourists could travel to distant places for recreation.

The end of the war released an affluent, restless population with abundant leisure. Tens of millions of people sought their national parks, spending millions of dollars which served as a catalyst to all the myriad businesses and industries dependent on travel and recreation. Appropriations did not keep pace with this invasion of the parks, and as a park director commented, "The American people are loving their parks to death."

Supported by citizens organizations, the park service urgently requested funds from congress, with some success. But by 1953 only $33,000,000 was being provided to administer 180 areas. Antiquated accommodations were deteriorating, roads were being pounded to ruin, campgrounds were unable to withstand constant overuse: the parks were being worn out. "Mission 66," a ten-year, $459,000,000 conservation, improvement and development program, was announced in 1956 by C. L. Wirth, park service director.

New projects and the backlog of deferred construction were started immediately. The Sierra club, the Wilderness society, the National Parks association and other nongovernmental conservation organizations supported the program and offered their advice. They supported the park service in its insistence on the importance of ensuring that physical development did not impair the wilderness character of the parks and monuments, and they also approved of the decision to concentrate visitor and personnel facilities (if required to be built inside the parks) in a limited number of restricted localities connected by motor roads, leaving 95% of the land in its undisturbed natural state.

The park service's work in interpreting its areas provides factual information about scenic features, wildlife, geology, botany, history or archaeology, and also helps the visitor to widen his interests and knowledge. A staff of scientists, naturalists, historians, museum and educational experts, augmented during the travel seasons by additional ranger-naturalists and other interpretive personnel, conduct field trips, staff museums and devise original methods of enlarging the visitor's appreciation of what he sees.

Such visitor facilities as roads, trails, campgrounds and utilities are provided by the park service. Services for which a charge is made—hotels and lodges, cabins, restaurants, automobile services, buses, packhorses and other similar services—are under private management.

If a facility or the land it occupies is owned by the federal government, the concessioner operates under a contract with the park service which regulates the character and financial aspects of the concession. There remain several hundred thousand acres within the parks held in nonfederal ownership (which are gradually being acquired by purchase or exchange), and visitor facilities on these lands are not under government control.

In all of its activities, the park service is guided by the statutory advisory board on national parks, historic sites, buildings and monuments.

(*See* also articles on the various national parks. For state parks *see* articles on the various states.)

National Forests: Wilderness, Primitive and Wild Areas.—As the United States was settled, more and more land was of course cleared of forests, and not until 1877 was official recognition given to the danger inherent in the practice. In that year the secretary of the interior, Carl Schurz, aroused congressional interest in retaining permanent forests in public ownership and in improving administration of the federal real estate. This led to the beginning of a system of forest reserves authorized in 1891; 30 were created by Presidents Benjamin Harrison and Grover Cleveland. Gifford Pinchot (*q.v.*), appointed chief of the forestry division in 1898, vigorously promoted the old-world concept of forest management through sound forest practices, enforced on public lands by laws and regulations imposed by the government as custodian of their resources. Pres. Theodore Roosevelt, who strongly supported this judgment, strengthened the federal interest in forest resources by assigning responsibility in 1905 to a new forest service in the department of agriculture, with Pinchot as chief forester, and created additional national forests. The practice of reserving portions of the federal real estate for regulated use and perpetuation of their resources was gradually extended to many aspects of a national conservation program.

Initially, the national forests were intended to safeguard watersheds (and were therefore located where preservation of water resources was a vital social and economic consideration) and to ensure a permanent supply of timber, harvested by private operators under forest service regulation. Since the national forests include large areas of grassland, grazing of livestock was soon added as a proper use. Mining laws apply to these lands, hunting of wildlife in accordance with state law is permitted, reclamation and power projects are located within them and other utilization of resources is authorized by law and regulation. This concept of multiple use is the conscious goal of administration of the national forests as a whole, although opinion varies as to whether this term should be construed to mean various uses on the same area, or whether emphasis on, or limitation to, the highest or most significant use should be applied on respective parts of a given area.

Even under careful regulation most of these activities change the character of the terrain and convert primeval wilderness into artificially controlled environment. Aldo Leopold of the University of Wisconsin was the first eloquent advocate of the wilderness concept: undisturbed wilderness itself is a resource of value; present and future generations require opportunity to experience the inspiration and surcease from an increasingly mechanized culture through healthful outdoor pursuits undertaken by individual effort; and those who inherit these resources should be bequeathed some virgin forests and unmodified open spaces which they could determine how to enjoy and use in light of the cultural patterns of their day. In 1921 Leopold aroused official interest in this proposition, and in 1924 the Gila Wilderness area was established in the Gila National forest in New Mexico as the first of what was to become a series of such reservations. In 1929 Regulation L-20 was promulgated under which several chiefs of the forest service established 72 primitive areas totaling nearly 14,000,000 ac. between 1930 and 1939. The wilderness area system was given another strong impetus in 1939 when regulations were set forth providing for the establishment of wilderness areas of more than 100,000 ac. each by the secretary of agriculture and the establishment of suitable tracts of between 5,000 and 100,000 ac. by the chief forester. The existing primitive areas which had been established since 1929 continued in effect but were scheduled for restudy and reclassification within the new definitions. The wilderness concept received vigorous popular support, especially through the educational program undertaken by the Wilderness society and private citizens throughout the country.

Within the wilderness, wild and primitive areas and the Boundary Waters canoe area, no developments are permitted which are detrimental to the preservation of primitive conditions of transportation and environment. Roads may not be built in them nor

TABLE II.—*Principal Refuges Administered by the United States Bureau of Sport Fisheries and Wildlife*

Name and location	Total gross acreage	Date established	Principal features
Big Game Refuges and Game Ranges			
Arctic National Wildlife range (Alaska)	8,900,000	1960	Undisturbed arctic coastal environment and eastern Brooks range; grizzly and polar bears, Dall sheep, caribou, moose, wolf, wolverine, etc.
Cabeza Prieta Game range (Arizona)	860,000	1939	Mexican antelope, Gaillard bighorn, peccary; sonoran desert
Charles M. Russell National Wildlife range (Montana)	951,302	1936	Pronghorn, Rocky mountain bighorn, deer, elk, upland game birds; sagebrush basin
Charles Sheldon Antelope Range and refuge (Nevada-Oregon)	544,525	1936	Pronghorn antelope, mule deer, sage hen, waterfowl; sonoran desert
Clarence Rhode National Wildlife range (Alaska)	1,870,000	1960	Low-lying tundra on northwestern coast near Bering sea; waterfowl, fur-bearing mammals, etc.
Desert Game range (Nevada)	2,188,379	1936	Pronghorn, Nelson bighorn, mule deer; sonoran desert
Fort Niobrara National Wildlife refuge (Nebraska)	19,122	1912	Bison, Texas longhorn cattle, elk, beaver, upland birds
Hart Mountain National Antelope refuge (Oregon)	240,731	1936	Pronghorn, mule deer, upland birds; sagebrush plateau
Izembek National Wildlife range (Alaska)	415,016	1960	Waterfowl nesting and feeding grounds on the Alaskan peninsula; brown bear, caribou
Kenai National Moose range (Alaska)	1,730,000	1941	Kenai moose, brown bear, Dall sheep, mountain goat, furbearers, birds; rugged wilderness of mountains, swamps, lakes and rivers
Kodiak National Wildlife refuge (Alaska)	1,815,000	1941	Kodiak bear, deer, waterfowl, colonial seabirds; forested Kodiak Island
Kofa Game range (Arizona)	660,000	1939	Gaillard bighorn, sonoran desert wildlife and vegetation, including rare *Washingtonia filifera* palm
Little Pend Oreille National Wildlife refuge (Washington)	43,959	1939	Upland birds, deer, black bear
National Bison range (Montana)	18,541	1908	300 to 400 bison, elk, deer, Rocky mountain bighorn; high prairie
National Elk refuge (Wyoming)	23,754	1912	Winter range of southern Yellowstone elk herd, trumpeter swan, sandhill crane, beaver; in Jackson Hole basin adjacent to Grand Teton National park
National Key Deer refuge (Florida)	6,745	1954	Rare dwarf Key deer, spoonbill, great white heron; on Florida Keys
Nunivak National Wildlife refuge (Alaska)	1,109,384	1929	Musk ox, reindeer, shorebirds; tundra
Pribilof Islands reservation (Alaska)	50,163	1909	Established to protect endangered fur seals, which had increased to 1,500,000 animals in 1959; controlled harvesting under bureau of commercial fisheries; colonial seabirds
San Andreas National Wildlife refuge (New Mexico)	57,217	1941	Nelson bighorn, deer, birdlife; sonoran desert
Simeonof National Wildlife refuge (Alaska)	10,442	1958	In southeastern part of Shumagin Island chain; sea otters
Sullys Hill National Game preserve (North Dakota)	1,674	1914	Bison, elk, deer, goose
Wichita Mountains Wildlife refuge (Oklahoma)	59,020	1905	Bison, elk, deer, pronghorn, longhorn cattle, turkey, rare Mississippi kite, waterfowl; upland prairies and mountain range

Name and location	Total gross acreage	Date established	Principal features
Migratory Bird Refuges General			
Aleutian Islands Wildlife refuge (Alaska)	2,720,235	1913	50 major islands extending 1,200 miles from Unimak to Attu; active volcanoes, Pacific coastland arctic tundra; rare sea otters, colonial seabirds, shorebirds, waterfowl, bear, whale, seal
Bering Sea Wildlife refuge (Alaska)	41,113	1909	Elders and other sea ducks, alcidae, arctic fox; tundra
Great White Heron Wildlife refuge (Florida)	1,997	1938	Great white heron, spoonbill, Key deer, mangrove keys
Okefenokee Wildlife refuge (Georgia)	330,973	1937	Crane, ibis, egret, limpkin, alligator, furbearers; primeval bald cypress swamp
Santa Ana Wildlife refuge (Texas)	1,981	1943	Remnant of tropical forest on Rio Grande river; tree duck, chachalaca and other birdlife with Mexican affinities
Migratory Bird Refuges Waterfowl			
Aransas Wildlife refuge (Texas)	47,261	1937	Sole wintering ground of rare whooping crane; abundant wintering waterfowl, migratory land birds and shorebirds; spoonbill, egret and heron rookeries; deer, peccary; peninsula on Gulf of Mexico
Bear River Migratory Bird refuge (Utah)	64,895	1928	Vast marshes of Bear river delta on Great Salt lake; millions of nesting and migratory ducks and geese; 200 species of birds recorded; furbearers
Cape Romain Wildlife refuge (South Carolina)	34,698	1932	Atlantic coastal marshes and islands; waterfowl, shorebirds, rail, loggerhead turtle, furbearers
Delta Wildlife refuge (Louisiana)	48,799	1935	Vast marshes on coast of Gulf of Mexico; major wintering grounds of blue, snow and other geese; abundant ducks, herons, rails and other birds; muskrat
Lacassine Wildlife refuge (Louisiana)	31,125	1937	
Sabine Wildlife refuge (Louisiana)	142,717	1937	
Kentucky Woodlands (Kentucky)	65,712	1938	Upland hardwood forests; eastern turkey, grouse, waterfowl
Lower Klamath (California)	21,459	1908	Vast restored marshes on Pacific waterfowl flyway; millions of geese and ducks, white pelicans, shorebirds, herons, upland birds, waterfowl
Sacramento (California)	10,776	1937	
Tule Lake (California)	37,337	1928	
Des Lacs (North Dakota)	18,881	1935	River marshes in northern prairies, restored to provide waterfowl nesting, feeding and wintering grounds; prairie chicken, sharp-tailed grouse
Lower Souris (North Dakota)	58,693	1935	
Upper Souris (North Dakota)	32,089	1935	
Loxahatchee (Florida)	145,525	1951	Subtropical swamp created by diked reserve, waterfowl wintering ground; limpkin, rare Everglade kite
Malheur (Oregon)	180,851	1908	Restored river marshes on Pacific waterfowl flyway; abundant birdlife, antelope, muskrat, beaver
Upper Klamath (Oregon)	12,533	1928	
Mattamuskeet (North Carolina)	50,177	1934	Atlantic flyway wintering grounds for waterfowl, especially whistling swan; furbearers
Swanquarter (North Carolina)	15,501	1932	
Red Rock Lakes (Montana)	39,946	1935	Lakes and marshes on continental divide; principal U.S. breeding ground of rare trumpeter swan; Shiras moose, furbearers
White River (Arkansas)	112,313	1935	Bottomland hardwood forest; abundant waterfowl, herons, turkeys, songbirds, furbearers

timber harvested (except in one-half of the canoe area under certain specific regulations), and other commercial uses are kept to a minimum. Hunting is permitted, since the states have not ceded jurisdiction over the wildlife there.

Unlike the national park system, the wilderness area system is subject to alteration of boundaries and change of policy by executive order within the department of agriculture; congressional action is not required. Certain citizens' organizations feel that it should be, to ensure the permanence of the protection afforded by the system, and legislation to that end was introduced in congress.

Most of the wilderness and primitive areas are west of the Great Plains. Robert Marshall described them as "regions which contain no permanent inhabitants, possess no means of mechanical conveyance, and are sufficiently spacious that a person may spend at least a week or two of travel in them without crossing his own tracks. The dominant attributes of such areas are: first, that visitors to them have to depend exclusively on their own efforts for survival; and, second, that they preserve as nearly as possible the essential features of the primitive environment." Most of them are high, rugged terrain of peaks and forests, tundra and mountain glades, clear rivers and lakes. Some are vast stretches of arid and semiarid country, interspersed with varied ecological conditions. Others have special attributes, such as the Boundary Waters canoe area (formerly known as the Superior Roadless area) in Minnesota, which protects the finest lakeland canoeing country in the United States by prohibiting logging on shorelines or the use of airplanes for transport, and which is contiguous with similar regions in Canada's Quetico Provincial park, in Ontario. Hikers and campers may follow thousands of miles of trails, on foot or with packhorses, to experience the kind of life their forefathers knew. The wild areas provide similar pursuits but are of smaller size. They are equally valuable as undisturbed examples of primeval ecology important to scientific research and for the determination of proper conservation practices on other land.

Wildlife Refuges.—Before the advent of white man, the American continent teemed with wildlife. Bison in the millions roamed the eastern forests and Great Plains. Pronghorn antelope may have been even more numerous. Passenger pigeons, more than a billion in a flock, nested in the hardwood forests. Waterfowl bred by the tens of millions in lakes and sloughs and marshes. Great rookeries of egrets, ibises and other herons inhabited the southern swamps. Beavers and other furbearers filled the waters of the forests, prairies and coastal swales. North America supported as many species and greater numbers of birds and mammals than any other temperate region on the earth.

Loss of the bulk of this wildlife heritage is part of the price the United States has paid for its civilization. The forest habitat of deer, bear, moose and many other species gave way to clearings as first the eastern and midwestern hardwoods were cut, and then vast stands of western conifers were logged. The prairies and plains became farms, many of their natural lakes, potholes and marshes were drained and plowed. Cities and highways occupied extensive acreages where once myriad animals lived. The pioneer settlers lived off the game of the land until cattle usurped the ranges. Meat from wild animals supported the rising cities; hundreds of thousands of barrels of passenger pigeons and Eskimo curlews, among other species, were shipped from St. Louis and other midwestern cities to cities in the east. Bison and antelope were slaughtered nearly to extinction, and the vogue for plumes on women's hats led to decimation of the egret and heron rookeries.

During the second half of the 19th century the states began to enact game laws, but enforcement was weak until national sentiment stimulated more effective protection under state game and conservation commissions. Fortunately, action came in time to enable most species to survive, but the passenger pigeon became extinct in 1914 and some species and subspecies of other animals no longer exist. The ranges of many animals, such as the grizzly bear and timber wolf, were restricted to a small number of protected localities, especially in national and state parks, refuges and preserves. A more thoughtful type of sportsman began to exert influence and to promote funds for restoration of endangered animals. The American Bison society purchased the last intact bison herd left in the United States and shipped it to Yellowstone National park, where it thrived; in the 1960s, more than 6,000 bison existed in the United States and additional herds inhabited reserves in Canada. Pronghorn antelope were reestablished in many places and spread into adjacent regions. Elk recovered so successfully under reasonable laws and on protected ranges that new herds were established in many parts of the country.

White-tailed deer actually benefited from the conversion of dense forests into smaller woodlands bordered by open terrain and may be more numerous now than in aboriginal times.

The vigorous interest taken by the federal government in wildlife restoration has been primary in the success of this program. On July 1, 1885, the branch of economic ornithology was established in the division of entomology, U.S. department of agriculture; it became the bureau of biological survey in 1905 under the direction of C. Hart Merriam. Originally designed to undertake research into the economic importance of birds and mammals, the bureau achieved international eminence as a scientific institution. It administered the Lacey act of 1900 which prohibited shipment across state boundaries of game taken illegally, and gradually market hunting was eliminated. Under the Migratory Bird Treaty act of 1918, the bureau was given power to extend federal protection to avian species that migrated between Canada and the United States; in 1937 a similar treaty with Mexico broadened this power.

Prior to ratification of these treaties, conservation of wildlife had been a responsibility only of the states, except in the national park system where jurisdiction over wildlife has been ceded to the federal government; these conventions enabled the federal government to share this responsibility.

Reservation of federal land as national wildlife refuges was accomplished initially by executive orders of the president, the first refuge being the three-acre Pelican Island off the east coast of Florida, established by Theodore Roosevelt in 1903. Many early bird sanctuaries, however, were created by the National Audubon society, a citizens' organization, to preserve egret rookeries in the south. The severe decline of waterfowl and shore birds because of overshooting and drought, and diminishing populations of larger mammals, evident during the first decades of the 20th century, stimulated reservation of large federal units such as Malheur and Upper Klamath National wildlife refuges in Oregon, the Pribilof Islands reservation in Alaska, the National Bison range in Montana and the Wichita Mountains Wildlife refuge in Oklahoma. By 1929, there were 87 federal refuges in 24 states and the territories.

The Migratory Bird Conservation act of 1929 provided broad legislative authority for refuge acquisition and development and some funds were appropriated for the programs. A second decline in the waterfowl population became evident, and under the dynamic leadership of Director J. N. Darling new sources of funds for the refuge program were provided. The Migratory Bird Hunting Stamp act of 1934 required all waterfowl hunters 16 years of age and over to have in their possession a federal stamp, and the Pittman-Robertson act of 1937 called for a 10% (later 11%) federal excise tax on sporting arms and ammunition to be allocated to the states to pay three-quarters of the expense of wildlife restoration programs. By 1953 the federal grant amounted to $10,000,000 annually. Originally, refuges purchased with duck stamp money were inviolate but in 1949 the secretary of the interior was empowered to open one-quarter of the area of such refuges to public shooting if the status of the species' population warranted, and in 1958 this was increased to 40% of most refuges.

The 1940 Convention on Nature Protection and Wild Life Preservation in the Western Hemisphere extended the application of certain protective measures to those American republics ratifying the treaty. In 1939, the biological survey was transferred to the U.S. department of the interior and in 1940, together with the bureau of fisheries, became the fish and wildlife service; in 1958, it was reorganized as the bureau of sport fish-

eries and wildlife, a part of the United States fish and wildlife service.

The revival of once drastically decimated species, such as pronghorn antelopes, bighorn sheep, bison, white-tailed deer, mule deer and elk, has been due in significant measure to these refuges, as well as to the protection afforded by the national park system and state game reserves and improved laws.

Similarly, largely as a result of preservation and restoration of essential breeding, feeding and wintering habitat in federal and state refuges, combined with favourable continental weather cycles, waterfowl population trends of the continent reached a peak during the years 1952 to 1956. Unfavourable weather conditions over a large segment of the breeding habitat, starting in 1956, resulted in a marked population decline in some species of waterfowl, especially the diving duck species. The objective of preserving waterfowl nesting areas, migration resting places and winter feeding grounds was co-ordinated in planning and legislative programs with other conservation activities. Vast sums were spent not only to acquire existing habitat on coastal marshes, bottomlands on the principal river systems and interior sloughs, but also to restore great areas that had been drained. Many storage reservoirs and other impoundments built to secure water benefits proved invaluable as waterfowl sanctuaries. Continued research by the fish and wildlife service revealed that waterfowl follow certain routes or flyways to and from their nesting grounds, each flyway being used by the population nesting in a particular geographic region. Series of refuges have been established to serve the welfare of the respective populations during the entire course of their movements.

In spite of the success achieved in arresting waterfowl declines and in perpetuating the species of ducks, geese and swans, their future security requires increased efforts to offset continued conversion of essential habitat to other purposes.

The growth of such a large and varied system of federal refuges, and the corollary development of refuges and sanctuaries by the states and private organizations, is evidence of changed attitudes toward wildlife on the part of the American people. Since they seldom are dependent on game meat for food, hunting is regulated to preserve species for future generations, and most sportsmen's organizations support governmental controls. During the 20th century there developed a large body of public opinion interested in wildlife for its own sake and as a source of personal enjoyment and scientific study. Both of these interests have strongly endorsed refuge programs and the expenditure of tax revenues for this purpose.

II. CANADA

National parks in Canada are established by parliament and are administered by the national parks branch of the department of northern affairs and national resources. Banff, Jasper, Kootenay and Yoho National parks adjoin each other in the spectacular Rocky mountains, and Mt. Robson, Hamber and Mt. Assiniboine Provincial parks and Glacier National park, in British Columbia, extend the continuous protected complex to cover 13,000 sq.mi. These are accessible by highway and rail and have excellent visitor accommodations. Vast portions of these parks are true wilderness, enjoyed by explorers and mountaineers. Other national parks in the Canadian Rockies, in the forests and lakelands of the plains and eastward to the Atlantic coast, provide a variety of environment, recreation and wildlife. Except for recognition of

TABLE III.—*Principal Parks in Canada*

Name and location	Total gross area in sq.mi. (approx. acreage in parens)	Date established	Principal features
National Parks			
Banff (Alberta)	2,564 (1,641,000)	1885	Central Rocky mountain scenery, with peaks to 11,900 ft.; bighorn sheep, mountain goat, elk, moose, bear, etc.
Cape Breton Highlands (Nova Scotia)	367 (234,900)	1936	Rugged Atlantic and Gulf of St. Lawrence shoreline, with coves and forests
Elk Island (Alberta)	75 (48,000)	1913	Rolling prairie; fenced herds of mammals
Fundy (New Brunswick)	79 5 (50,900)	1948	Mixed conifer and hardwood forests rising above Bay of Fundy; moose, white-tailed deer, black bear and other wildlife
Georgian Bay Islands (Ontario)	5.4 (3,500)	1929	Tiny islands in Georgian bay, Lake Huron
Glacier (British Columbia)	521 (333,400)	1886	Rocky mountain wilderness; peaks, glaciers, lakes, conifer forests, abundant wildlife
Jasper (Alberta)	4,200 (2,688,000)	1907	Peaks to 12,394 ft., famous Columbia ice field covers 150 sq.mi.; conifer forests; abundant wildlife
Kootenay (British Columbia)	543 (347,500)	1920	Rocky mountain scenery and wildlife; hot springs
Mount Revelstoke (British Columbia)	100 (64,000)	1914	Rolling alpine plateau 6,000 ft. in elevation, snowfields, glaciers
Point Pelee (Ontario)	6 (3,800)	1918	Peninsula in Lake Erie, noted as sanctuary for birds
Prince Albert (Saskatchewan)	1,496 (957,400)	1927	Conifer and deciduous forest, lakeland with excellent canoeing; migratory waterfowl and other wildlife
Prince Edward Island	7 (4,500)	1937	25 mi. of forested coastline on Gulf of St. Lawrence, with beaches and bays; many kinds of small mammals
Riding Mountain (Manitoba)	1,148 (734,700)	1929	Forested plateau rising 1,000 ft. above the plains; many glacial lakes; abundant wildlife
St. Lawrence Islands (Ontario)	0.4 (260)	1914	Protects a mainland area and 12 of the Thousand Islands in the St. Lawrence river
Terra Nova (Newfoundland)	153 (97,920)	1957	Forests, barrens and rocky hills rising from sheltered sounds indenting Atlantic coast
National Parks (Cont.)			
Waterton Lakes (Alberta)	203 (129,900)	1895	Canadian portion of Waterton-Glacier International Peace park. Rocky mountain ecology, noted for lakes, wild flowers and animals
Wood Buffalo (Alberta Northwest Territories)	17,300 (11,072,000)	1922	Protects only remaining herd of wood buffalo in its natural state and related plains buffalo, the total herd numbering 12,000 to 14,000 animals
Yoho (British Columbia)	507 (324,500)	1886	Glaciers, ice fields, lakes and waterfalls among canyons and peaks, in Rocky mountains
Provincial Parks (partial list)			
Cypress Hills (Alberta)	78 (49,920)	1952	Rare specimens of preglacial plant and insect life
Garibaldi (British Columbia)	966 (618,097)	1927	Pacific coast mainland, with mountain lakes, peaks and glaciers
Hamber (British Columbia)	95 (60,585)	1941	Northern wilderness conifer forest, adjoining Jasper and Banff National parks, on Big Bend highway
Mt. Assiniboine (British Columbia)	20 (12,850)	1922	Outstanding Rocky mountain scenery, south of Banff
Mt. Robson (British Columbia)	803 (513,920)	1913	Rocky mountain peaks, lakes and glaciers
Strathcona (British Columbia)	829 (530,319)	1911	Peaks, glaciers, alpine meadows and Della falls, in centre of Vancouver Island
Tweedsmuir (British Columbia)	3,788 (2,424,400)	1938	Vast mountain wilderness area, with abundant wildlife
Algonquin (Ontario)	2,910 (1,862,144)	1893	Wilderness area and wildlife preserve in northern forests
Quetico (Ontario)	1,795 (1,148,800)	1909	Forested wilderness lakeland, adjoining Boundary Waters canoe area in U.S.
Gaspesian (Quebec)	514 (328,960)	1937	Rugged terrain on Gaspé peninsula, reserved to protect caribou and other wildlife
Laurentide (Quebec)	3,612 (2,312,100)	1895	Park containing many lakes and tumultuous rivers; abundant wildlife
La Verendrye (Quebec)	4,746 (3,038,000)	1939	Wild terrain of forests, lakes and rivers
Lac La Ronge (Saskatchewan)	1,140 (729,600)	1939	Representative northern spruce and poplar forests, with many species of wildlife

native Indian rights, hunting is prohibited, and legislative action is required to alter boundaries.

Six provinces have set aside provincial parks, many as magnificently scenic and as important to wildlife as the national parks. They are administered under regulations promulgated by the respective provincial governments, and hunting is permitted in some of them. Tweedsmuir Provincial park, in British Columbia, is one of the largest wilderness areas (3,456,100 ac.) in North America. The Quetico Provincial park, in Ontario, protects 1,148,800 ac. of forested lakeland adjoining the Boundary Waters canoe area in Minnesota. Canada has reserved dozens of game preserves and wildlife sanctuaries, some of great size. Musk oxen, caribou and other abundant wildlife are safeguarded on about 1,000,000 ac. in the Northwest Territories, Yukon and Alberta. More than 1,200 sq.mi. of crown lands comprise bird sanctuaries under the Canadian wildlife service, and the provinces and local governments have reserved many other refuges. Until well into the 20th century much of Canada was remote wilderness, but the accelerated expansion of industrial exploration and development throughout the country, especially after World War II, increased the importance of these reservations in ensuring the survival of Canada's extraordinary wildlife populations.

III. AFRICA

Popular imagination envisions Africa as a continent still teeming with millions of wild animals roaming freely over velds, forests and jungles. Actually the habitat has been so restricted by human settlement and economic development and so many species of larger mammals have been hunted so ruthlessly that in many countries wildlife persists in significant numbers only where national parks and reserves have been established.

Even in the areas where the natural environment is preserved and the animals are protected, poaching by natives for meat and ivory endangers the wildlife populations. Parks and reserves are further threatened by pressures from native tribes to permit use of grasslands in national parks for cattle, frequently a symbol of wealth and prestige rather than a source of food, which have destroyed verdant pastures over wide ranges.

During the latter part of the 19th century the preservation of Africa's wildlife began to be a matter of concern, and various steps were taken in that direction (*see* WILDLIFE CONSERVATION: *International Co-operation*). The rise of independent native governments after World War II threatened to reverse these gains because of indifference and inexperience on the part of the new governments and the attitude of many native peoples that all land must be devoted to producing economic commodities to raise the standard of living for their increasing populations. Many tribes consider wildlife only a competitive nuisance, and poaching is both widespread and increasing.

Most of the new nations have retained the parks and reserves their predecessors established and are endeavouring to provide administrative machinery to handle them. The future of these areas and their natural resources depends on how effectively sound policies are applied. Various conferences, such as the one at the Northern Region, Tanganyika, in Sept. 1961, under the sponsorship of the Commission for Technical Cooperation in Africa South of the Sahara (CCTA) and the International Union for Conservation of Nature were held to analyze these problems.

By the 1960s there were about 25 African countries with national parks or equivalent reserves, protecting more than 265,000 sq.mi. Kruger National park, in Transvaal, Republic of South Africa, covers 8,000 sq.mi. and presents one of the most extraordinary exhibits on earth of wild animals. From their cars, visitors can watch lions, elephants, giraffes, hippopotamuses, many kinds of antelopes and other creatures living their natural lives. Established in 1898 in response to Pres. Paul Kruger's warning that African wildlife would be exterminated unless protected, the park was enlarged in 1926 and is administered by a National Park Board of Trustees with official and civilian members. This board also supervises four other national parks, of which the Kalahari Gemsbok National park, in Cape Province and Botswana, created in 1931, is a unique sanctuary for oryx, springbok, red hartebeest, kudus, elands, ostriches and many other animals of the arid desert. The few remaining Bushmen (*q.v.*) also are found there. Other parks in South Africa are administered by similar but provincial boards.

Three national parks in Cape Province are notable for rare species protected in them. Addo National park preserves the last Addo elephants; Swellendam National park safeguards a remnant herd of bontebok antelopes; the Mountain Zebra National park has ensured the survival of that race of zebras. The Umfolozi reserve in Natal has a population of about 300 rare southern white (or square-lipped) rhinoceroses (1959), as well as black rhinoceroses. The Orange Free State has a number of game reserves, of which the Somerville Game reserve (26,000 ac.) is the most important. There are also many other reserves in South Africa where hunting is prohibited or strictly controlled, or where particular botanical, zoological, geological or historical features or specimens are protected.

Outstanding among the reserves of the world are the national parks of the Democratic Republic of the Congo. These were most efficiently protected under the careful policies of the Institut des Parcs Nationaux du Congo Belge, and in spite of the confusion attending establishment of an independent government the new administration continued the protection of these areas to the best of its ability. Albert National park was reserved in 1925, initially to protect the shy mountain gorilla, but by subsequent acts and royal decrees it was enlarged as a reserve dedicated to the protection of all animal life and vegetation and to scientific and ecological exploration and study. This park (part in Rwanda), and three others established later, Kagera National park (Rwanda), Garamba National park and Upemba National park, safeguard a wide variety of natural environment from the snow-clad peaks of the Ruwenzoris to the jungle rain forests of the Congo basin. They are the home of the pygmy people and the habitat of such rare animals as the okapi and bongo, as well as many other species. Scientists from all over the world come to these parks, and their reports on every ecological aspect of the region published by the Institut are invaluable contributions to knowledge of Africa and to its development. Because of the scientific importance of preserving natural conditions unchanged, only certain portions of the Albert National park and of the Kagera National park are open to tourists.

In Rhodesia an official program endeavouring to eliminate the tsetse fly, carrier of the nagana parasite in cattle, by widespread slaughter of the larger wild animals has led to scarcity of most wildlife except in national parks and forest reserves, where animals are protected. The Wankie National park with the adjacent Robin Game sanctuary covers a large area where tourists are encouraged to come between June and November to see great herds of antelope, buffalo, elephant, many species of birds and other animals. Victoria Falls National park to the north preserves one of the most famous scenic features in Africa.

Zambia established Kafue National park in 1950 in the basin of the Kafue river; it is a reserve larger than Kruger National park. Native tribes, occupying 5% of the park, retain certain rights, but passage through the reserve is restricted to determined routes. The park is open to tourists and supports a wealth of wildlife. Zambia also possesses game reserves and "controlled areas" where the number of animals allowed to be killed by nonresidents is regulated according to the population of those animals; there are also reserves for fish protection, forest reserves and others where careful policies of protection are enforced. Some of these contain famous waterfalls, caves and other scenic and archaeological features.

In northern Tanzania eastward from Lake Victoria as far as the conservation area stretches the Serengeti National park, which preserves the finest assembly of plains animals in Africa. During the dry season the animals roam the comparatively well-watered western section of the park which the tsetse fly makes uninhabitable to man and livestock. The park contains the best extensive grassland range of central Africa, undamaged by the light grazing of the native animals. In the wet season, the wildlife migrates into the eastern area of the park and even farther eastward into the conservation area, where it comes into contact with thousands

TABLE IV.—*Principal Parks and Reserves in Africa*

Name and location	Total gross area in sq.mi. (approx acreage in parens.)	Date established	Principal features
ALGERIA			
Djurdjura	64 (40,900)	1935	High terrain of Djurdjura; conifer and cedar forests; monkey, boar, jackal, wildcat; raptores and other birds; reptiles and other wildlife
ANGOLA			
National Parks			
Cameia	3,861 (2,471,000)	1957	In the Haute-Cuenene; gnu and antelope
Bikuar	3,135 (2,006,400)	1964	Eland and antelope
Iôna	6,148 (3,934,700)	1937	Hartmann's zebra, rhinoceros, cheetah, other wildlife
Mupa	2,548 (1,630,700)	1964	Black rhinoceros, elephants, zebras, antelope
Quiçâma	3,846 (2,461,400)	1957	Abundant mammals and birds, especially elands and elephants
Reserves			
Cangandala	232 (148,480)	1963	Varied flora; rivers; giant sable antelopes
Luando	3,197 (2,046,100)	1938	Abundant wildlife, especially giant sable antelopes and elands
Milando	4,680 (2,995,200)	1951	Antelope, hippopotamus, lion and leopard
Moçâmedes	3,475 (2,224,000)	1957	Black rhinoceros, Hartmann's zebra, Burchell's gazelle, oryx, leopard, other wildlife
BOTSWANA			
Chobe Game reserve	4,500 (2,880,000)	1959	Elephants, sable antelopes, elands, kudus, ostriches, zebras, impalas, giraffes, hippopotamuses, lions, leopards, rhinoceroses, variety of birds
Kalahari Gemsbok National park	4,300 (2,752,000)	1931	Shares reserve with South Africa; acacia trees and desert shrubs; lions, elands, red hartebeests
Moremi Wildlife reserve	700 (448,000)	1961	All major species of Central African wildlife
CAMEROON			
Waza Game reserve	656 (420,100)	1934	Sudanese plains, wooded on the west; giraffe, antelope, aquatic and marsh birds
Bouba-Djida Nature reserve	849 (543,620)	1947	Wooded plains; rhinoceros, giant eland and others
Faro Nature reserve	1,270 (815,450)	1947	Uninhabited plains; rhinoceros, giant eland and other animals
Campo Kribi Game reserve	1,200 (768,000)	1932	Dense equatorial forest and swamp, completely uninhabited
Dja Game reserve	1,930 (1,235,530)	1950	Equatorial forest inhabited by diverse wildlife
Bafia reserve	162 (103,784)	1949	Buffaloes, hippopotamuses, monkeys, wild boars
Douala-Edéa reserve	618 (395,367)	1932	Elephants, monkeys, guibs, chevrotains, hippopotamuses
Bénoué reserve	695 (444,790)	1947	Elephants, buffaloes, rhinoceroses, elands, antelopes, lions, waterbucks
CENTRAL AFRICAN REPUBLIC			
André Félix National park	656 (419,840)	1959	Grassland with marshy savanna during rainy season; antelopes, buffaloes, giraffes, elephants, lions, ostriches
Bamingui-Bangoran National park	3,906 (2,500,000)	1933	Broad peneplain with great granitic-gneissic outcrops; lagoons important for protection and reproduction of black rhinoceros
Nana Barya reserve	849 (543,360)	1953	Wooded and herbaceous grasslands; elephants, buffaloes, giant elands, rhinoceroses
Ouandjia-Vakaga reserve	3,770 (2,412,500)	1940	Upper basin of Chari river; antelopes, buffaloes, giraffes, elephants, lions, ostriches
Saint-Floris National park	386 (247,000)	1933	Forested sudanese grassland; elephants, lions, giraffes
Zemongo reserve	3,633 (2,325,000)	1940	Hilly wooded grasslands broken by gallery forests; special protection for elephants and rhinoceroses
CHAD			
Manda National park	417 (266,760)	1965	Elephants, hippopotamuses, buffaloes, kudus, giraffes, elands, gazelles, hyenas, lions, birds
CHAD (*Cont.*)			
Zakouma National park	1,145 (732,684)	1963	Meandering rivers; rhinoceroses, elephants, elands, lions, panthers, lynxes, birds, crocodiles, snakes
Bahr Salamat reserve	7,950 (5,088,200)	1964	Plains flooded during rainy season, elephants, hippopotamuses, giraffes, antelopes, kudus, gazelles, panthers, birds
Dougia reserve	299 (146,718)	1961	Elephants, gazelles, antelopes, lions, aardvarks, birds
Siniaka Minia reserve	1,644 (1,052,220)	1961	Kudus, elands, hyenas, birds, giraffes, lions
REPUBLIC OF CONGO			
Odzala National park	424 (271,400)	1940	Almost inaccessible area in western Congo; abundant forest wildlife, including elephant, bongo antelope, anthropoid apes; pygmies
DEMOCRATIC REPUBLIC OF THE CONGO			
Albert National park	3,160 (2,022,400)	1929; 1934	A world-famous national park on the Uganda and Rep. of Rwanda border; equatorial jungles, Ruwenzori mountains (Mountains of the Moon) and Virunga volcanoes with cloud forests, giant lobelias and heather; most of Lake Edward; great variety of wildlife, including mountain gorilla, elephant, thousands of hippopotamuses; pygmies
Garamba National park	1,900 (1,216,000)	1938	Grass and wooded savannas on ancient peneplain, on northern border; abundant wildlife, including white rhinoceros, giraffe, elephant, hippopotamus and other plains species
Upemba National park	4,529 (2,932,300)	1939	Vast plains, with deep river valleys rising to forested Kibara plateaus, in central Katanga; varied animal life, including eland, klipspringer and other antelope, many elephants and buffalo, lion and other mammals, aquatic birds
DAHOMEY			
De la Boucle de la Pendjari National park	1,064 (680,775)	1954	Savanna grasses and prairies; buffaloes, lions, antelopes, wild boars, some elephants
W du Niger National park	1,940 (1,241,704)	1952	Many elephants, lions, wild boars, hippopotamuses
ETHIOPIA			
Managasha National park	12 (7,500)	1958	On mountain range west of Addis Ababa; experimental forestry practiced; most beautiful sections maintained in primeval state; wildlife strictly protected
FRENCH SOMALILAND			
Mt Goudah reserve	38 (24,320)	1939	Mt. Goudah and surrounding primitive forests of junipers (*Juniperus procera*), firs, *Medenia* palm, dai
GHANA			
Mole River Game reserve	900 (576,000)	1962	Owned by the Gonja people, managed for complete protection of wildlife; savanna forest
GUINEA			
Monts Nimba Nature reserve	56 (35,831)	1944	On boundary of Ivory Coast and Guinea; rich tropical forests; varied wildlife, chimpanzees; important region for ecological study; more than 200 species of endemic plants
IVORY COAST			
Banco National park	12 (7,500)	1935	Dense ancient forest and forestry school
Bouna Game reserve	3,861 (2,471,100)	1958	Peneplain grasslands and dry woodlands; most large west African antelopes, carnivores, monkeys, etc.
Tai Game reserve	1,641 (1,050,200)	1926	Little-explored plains, with abundant wildlife
Elephant Plain reserve	76.5 (49,000)	1958	Protection of elephants
Monts Nimba Nature reserve	19 (12,350)	1944	Rich tropical forests; varied wildlife, chimpanzees; 200 species of endemic plants

TABLE IV.—*Principal Parks and Reserves in Africa (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
KENYA			
National Parks			
Aberdare	228 (145,900)	1950	Higher elevations of Aberdare range, with lakes, dense forests, bamboo and moorland, alpine meadows; abundant populations of elephant, buffalo, rhinoceros and other wildlife, including rare bongo antelope
Lake Nakuru	18 (11,520)	1961	In the floor of the Rift valley; flamingos (between 1 and 2 million); 380 different species of birds
Mount Kenya	227 (145,300)	1949	Elevations above 11,000 ft. surrounding Mt. Kenya (17,058 ft.), with glaciers, tarns and moraines; heavily forested, alpine meadows; many birds and smaller mammals but no larger animals
Nairobi	44 (28,200)	1948	Open plains and acacia savanna, deep river valleys, near Nairobi; Ngong reserve contiguous; famous place to see lion, cheetah, leopard, rhinoceros, giraffe
Tsavo	8,034 (5,141,800)	1948	Semiarid plains, with dense brush and two principal rivers, lava cones, the Mzimi springs; baobab, acacia, euphorbia; elephant, rhinoceros, hippopotamus, lion, many species of antelope; divided into Tsavo East and Tsavo West
African District Council Reserves			
Masai Amboseli Game reserve	1,259 (805,800)	1948	Open level terrain at about 4,000 ft., north of Mt. Kilimanjaro; arid, interspersed with swamps and springs, belts of acacia forest; dry salt bed of Lake Amboseli; native trust land of Masai tribe; outstanding exhibit of most east African mammals and birds; competition with cattle being reduced by providing artificial water supplies; transferred to the African District council in 1961
Masai Mara Game reserve	700 (448,000)	1948	Open rolling plains with thickets and riverine vegetation; abundant wildlife, including most east African mammals; part of Masai land unit, transferred to the African District council in 1961
Meru Game reserve	600 (384,000)	1959	Foothills of Nyambeni hills to Tana river; grassland, rain forest and riverine forest; abundant variety of wildlife, *Oryx beisa*, reticulated giraffe, Grévy's zebra
Samburu Game reserve	44 (28,200)	1960	3,000 ft. elevation; semidesert scrub, abundant bird life; great variety of antelope; elephant, buffalo, leopard, reticulated giraffe, Grévy's zebra
LIBERIA			
Mt. Wutini reserve	23 (15,000)		Rolling ground to rugged terrain; wildlife refuge
MALAGASY REPUBLIC			
Ambre Mountain National park	71 (45,500)	1958	Volcano with smaller craters and lakes; dense deciduous moss forest; lemurs
Isalo National park	314 (201,400)		Runiform massif, limestone outcrops, lemurs, rare birds
11 nature reserves	1,639 (1,482,000)	1927–1952	Protects birds and small mammals, especially lemurs; forests with orchids and lepidoptera
MALAWI			
National Park			
Nyika Plateau	325 (208,000)	1965	High mountain grassland with evergreen forest relics at 7,000 to 8,000 ft.; eland, zebra, hartebeest, reedbuck, lion and leopard
Game Reserves			
Kasungu	800 (512,000)	1956	Open grassland and grassy woodland; lion, zebra, oribi, klipspringer, elephant, black rhinoceros, buffalo, eland, leopard, hartebeest
MALAWI (*Cont.*)			
Game Reserves (Cont.)			
Lengwe	45 (28,800)	1960	Dry woodland with open grassland, large areas of dense thorn thicket; Nyala antelope, bush buck, buffalo, impala, other wildlife
Majete	70 (44,800)	1960	Leopard, lion, zebra, klipspringer, elephant, eland, other wildlife
Mwabri	60 (38,400)	1954	Dry woodland with grassy water courses; leopard, lion, hartebeest, black rhinoceros, other wildlife
Nkhota-Kota	680 (435,200)	1954	Lion, zebra, black rhinoceros, klipspringer, other wildlife
MALI			
Boucle du Baoulé National park	2,977 (1,905,182)	1954	Baoulé river basin, with sudanese savanna and forests; elephant, giant eland, sable antelope and other wildlife; total area includes 3 reserves attached to park
MAURITIUS			
Bel Ombre National reserve	3.5 (2,271)	1951	Intermediate montane climax forest, with ebony
Macabe-Mare Longue reserve	2.5 (1,253)	1951	Upland climax high forest on lateritic soils
MOROCCO			
Tazekka National park	2.3 (1,450)	1950	Jebel Tazekka (1,979 m. [6,493 ft.]) in Middle Atlas range; high rainfall produces forest cover, including Atlantic cedar; wildlife
Toubkal National park	141 (90,000)	1942	High Atlas mountains, peaks rising to 4,185 m (13,730 ft); desert, with juniper and oak forests at higher altitudes; endemic plants; mouflon, mountain gazelle, endemic lake trout
MOZAMBIQUE			
Gorongosa National park	2,135 (136,600)	1935; 1960	Elephant, buffalo, kudu, eland, zebra, rhinoceros, hippopotamus, other abundant wildlife
Niassa Game reserve	5,792 (370,700)	1960	Protection of all animals
Maputo Game reserve	290 (18,600)	1960	Protection of elephants
Marromeu Game reserve	579 (51,900)	1960	Protection of buffalo
NIGERIA			
8 game reserves	5,348 (3,422,500)		Regulated hunting; giraffe, elephant, waterbuck, kob and other wildlife, there are also several smaller animal life sanctuaries
RHODESIA			
Robert McIlwaine National park	20 (12,800)	1952	Bushmen's paintings; lake
Matopos National park	153 (98,000)	1953	Granite *kopjes* and Bushmen's cave paintings; sable and other antelope
Rhodes Inyanga National park	133 (85,100)	1950	Mountainous country; exotic and indigenous forests; wildlife
Victoria Falls National park	205 (131,200)	1952	Victoria falls, 355 ft. high, 5,580 ft long, in Zambezi valley; rain forest; elephant, sable, roan and other antelopes; lion; many other species
Wankie National park	5,128 (3,281,900)	1950	Gemsbok, 2,000 elephants, buffalo, wildebeest, sable antelope, impala, roan antelope, kudu, lion and other wildlife
Kyle Dam Game reserve	35 (22,400)	1964	One of the largest reedbuck populations in southern Africa; hippopotamuses, buffaloes, elands, white rhinoceroses
RWANDA			
Kagera National park	970 (627,500)	1934	Verdant basin of Kagera river on Democratic Rep of the Congo border; varied animal life, with zebra, antelope and marsh birds predominating
SENEGAL			
Niokolo-Koba National park	965 (617,800)	1951	Limit of the northern sudan savanna; elephant, giant eland, antelope, carnivores, hippopotamus, civets, birds

TABLE IV.—*Principal Parks and Reserves in Africa (Continued)*

Name and location	Total gross area in sq mi. (approx. acreage in parens)	Date established	Principal features
SEYCHELLES			
Aldabra Islands Nature reserve	60 (38,400)	1955	Complete protection of giant tortoise and, on South Island, of all animals
Vallee de Mai reserve (Praslin Island)	0.07 (46)	1946	Protects *Coco de mer* palm and native birds
REPUBLIC OF SOUTH AFRICA			
National Parks			
Addo Elephant (Cape Province)	26.5 (16,900)	1931	Southern tip of province; impenetrable bush, habitat for 35 rare Addo elephants and scarce Cape buffalo; 11 species of extirpated antelope reintroduced, abundance of other mammals, birds and reptiles
Golden Gate Highlands (Orange Free State)	16.9 (10,800)	1963	Highlands park inhabited by eland, black wildebeest, springbok, red hartebeest
Kalahari Gemsbok National park	3,730 sq mi (2,387,200) in Cape province, 4,300 sq mi (2,752,000) in Botswana	1931	Bright red Kalahari sandveld, 5 in of rainfall annually, acacia trees and desert shrubs and grasses, Kalahari lion and other endemic species, especially gemsbok, springbok, eland, red hartebeest
Kruger (Transvaal province)	8,000 (5,120,000)	1898; 1926	World famous wildlife sanctuary, mostly open veld, other parts dense brush and open forests; most species of South African animal life
Mountain Zebra (Cape Province)	25.5 (16,300)	1937	Karroo mountain region, established especially to protect the very rare mountain zebra; other indigenous animals reintroduced, open to public
Royal Natal (Natal province)	32 (20,500)	1916	High scenery of Drakensberg mountains; gray rhebok, mountain reedbuck, other wildlife; Bushmen's paintings
Swellendam (Cape Province)	10.7 (6,800)	1931	Open river basin, habitat for 450 bontebok antelope, gray rhebok, gray duiker, steinbok, eland, red hartebeest
Nature Reserves			
Cape of Good Hope (Cape Province)	27 (17,300)	1939	On tip of Cape of Good Hope; rare vegetation, including blue *Disa* orchid, mimetes heath, Vaal rhebok, grysbok, etc.
Game Reserves			
Natal province			
Giant's Castle	92 (59,000)	1903; 1952	Open rugged grassland, peaks of Quathlamba Drakensberg range and headwaters of Mooi and Bushman's rivers, highland antelope, many leopard
Hluhluwe	89 (57,000)	1951	Almost every species of wildlife in Zululand, including white rhinoceros, black rhinoceros, impala, kudu, etc.
Ndumu	37 (23,700)	1924; 1947	Thorn savanna, *Ficus* riverine forests and a large lake, hippopotamus, crocodile, nyala
Nkuzi	97 (62,000)	1912	Thorn veld and *Ficus* forest; nyala, impala and some black rhinoceros
St. Lucia	190 (121,600)	1897; 1939	St. Lucia lake and estuary on False bay, and coastal scrub and jungle, hippopotamus and many kinds of birds
Umfolozi	112 (72,000)	1897	Rolling thorn veld; sanctuary for white rhinoceros
Orange Free State			
Willem Pretorius	40.6 (26,000)	1956	Open plains, bush and *kloofs* and Doornberg range; plains species of wildlife
Transvaal province			
Barberspan	14 (8,940)	1954	Ornithological research station on Lake Barberspan, thousands of waterfowl, flamingo, pelican and other birds
Loskop dam	41 (26,200)	1940	Protects wildlife on four farms bordering Loskop reservoir; cycads, including *Encephalartos*
SOUTHWEST AFRICA			
Etosha Game park	26,000 (16,640,000)	1928	Desert region from ocean to plains contiguous with Moçâmedes reserve in Angola; herds of elephants, springbok, zebras and blue wildebeest
SUDAN			
Boma reserve	533 (341,120)	1960	Boma mountain, Rub river, white-eared waterbucks, zebras, gazelles, hartebeests, giraffes, roan antelopes
Dindir National park	2,470 (1,580,800)	1939	Open savanna bush well suited to hoofed animals, especially roan antelope, kudu, giraffe, hartebeest, reedbuck, buffalo
Fangak Island reserve	50 (32,000)	1935	Primarily protects lechwes; swampy island with papyrus
Nimule National park	100 (64,000)	1954	Plateau, sparse timbered trees and scattered bush, main species is white rhinoceros; also elephant, buffalo, hippopotamus, waterbuck, hartebeest
Southern National park	6,500 (4,160,000)	1939	Dense and open forests and plains, especially giant eland, white rhinoceros, elephant, buffalo, giraffe, variety of smaller mammals
Juba reserve	120 (76,800)	1939	Rich green valleys, white rhinoceroses, elephants, buffaloes, hartebeests, oribis, duikers, waterbucks
Bengangai (Bongo) reserve	600 (384,000)	1939	Giant equatorial trees, dense thickets, natural habitat of bongo, also elephant, buffalo, giant forest hog, colobus monkey
Shambe reserve	400 (256,000)	1939	Primarily protects Nile lechwes; low marshy land surrounded by high savannas; white rhinoceroses, waterbucks, lions, leopards, giraffes, roan antelopes
Numotina reserve	1,000 (640,000)	1939	A semiupland with thick forest, rich vegetation and an abundance of water; elephant, buffalo, waterbuck, bushbuck, hartebeest
Soboloka reserve	450 (288,000)	1939	Primarily protects Barbary sheep and ibexes, on western bank of the Nile
Zerraffe reserve	2,700 (1,728,000)	1939	Island bounded by the White Nile and Zerraffe rivers, lowland with swamps on edges; especially protects the Nile lechwe; sitatunga, elephant, hippopotamus, buffalo
SWAZILAND			
Mlilwane Game sanctuary	1.7 (1,100)	1964	Giraffes, hippopotamuses, white rhinoceroses, kudus, nyalas, ostriches, crocodiles, white-tailed gnus, birds
TANZANIA			
National Parks			
Lake Manyara	123 (78,700)	1957; 1960	Five distinct vegetation zones; buffalo, elephant, lion, leopard, rhinoceros, many water birds, especially flamingo. Area lies between escarpment of rift wall and Lake Manyara
Mikumi	650 (416,000)	1964	Lies in a horseshoe of hills, variety of wildlife, good for viewing lion, elephant, buffalo, hyena, impala, giraffe, wart hog, hippopotamus, zebra, and wildebeest, many other species
Ngurdoto Crater	25 (16,000)	1960; 1962	Crater surrounded by rain forest; string of fresh water Momela lakes; from crater rim can be viewed buffalo, elephant, rhinoceros, giraffe, waterbuck, wart hog, and baboons on crater floor
Ruaha	5,000 (3,200,000)	1964	Along banks of the Great Ruaha river; fine elephant country; greater kudu, zebra, lion, waterbuck, ostrich, others
Serengeti	5,600 (3,584,000)	1929; 1951, 1959	Treeless plains, savanna type stretches, riverine bush, thick forest; chiefly famous for lions, more than 35 species of plains game, abundant bird life, more than 1 million animals, of which 300,000 are wildebeest

TABLE IV.—*Principal Parks and Reserves in Africa (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
TANZANIA (*Cont.*)			
Game Reserves			
Biharamulo	450 (288,000)	1959	Wooded rolling plains on shore of Lake Victoria, northern limit of range of sable antelope; Lichtenstein's hartebeest, and Sharp's steinbok
Gombe Stream	61 (39,000)	1943	Shore of Lake Tanganyika; mountain country, with woodland and gallery forest, and mountain meadows; chimpanzee, red colobus monkey
Katavi Plain	650 (416,000)	1951	Woodland, thornbush, plains and lakes; many buffalo, hippopotamuses, elephants, lion
Kilimanjaro	720 (460,800)	Before 1914; 1951	Summit of Mt. Kilimanjaro between 6,000 ft. at forest line to 19,340 ft., with rain forest, moorland, tundra and ice fields; animal life includes Harvey's and Abbott's duikers, elephant, buffalo, leopard, eland, colobus and blue monkeys, and other wildlife
Mkomazi	1,350 (864,000)	1951	Very arid hilly area; semidesert vegetation and animal life, including lesser kudu, oryx, gerenuk, rhinoceros, elephant and larger carnivora
Mt. Meru	99 (63,400)	Before 1914; 1951	Upper slopes of volcanic Mt. Meru from 5,500 to 14,979 ft., with rain forest, bamboo, cedar and heath; colobus monkey, giant forest hog, rhinoceros, elephant
Rungwa River	7,822 (5,006,100)	1951	Rolling wooded plains, with rocky ridges; sable and roan antelopes, greater kudu, elephant, buffalo
Selous	11,512 (7,367,700)	Before 1914; 1951	In Rufiji river basin, with open grasslands, patches of dense hardwood forest; primarily an elephant reserve
Tarangire	525 (336,000)	1957	Acacia thornbush and floodplains; elephant, rhinoceros, wildebeest, impala, Coke's hartebeest, eland, lesser kudu; ecological research station
Ngorongoro Conservation area	4,000 (2,560,000)	1956	Grass plains, thornbush, rain forest and mountain moorland, dominated by vast extinct Ngorongoro crater, rising over 11,000 ft., main gorge and Lake Eyasi branch of Rift valley; rhinoceros, elephant, buffalo, leopard, mountain reedbuck and giant forest hog in higher terrain; plains species lower down
TUNISIA			
Djebel Bou Hedma State park	508 (32,500)	1936	Plateau area in southern Tunisia, with remnant of acacia park land; gazelle mouflon
UGANDA			
Murchison Falls National park	1,504 (962,600)	1952	Includes famed Murchison falls and the Victoria Nile; mostly open grassy plains, large number of crocodiles, hippopotamuses and characteristic plains animals; aquatic birds
Queen Elizabeth National park	764 (489,000)	1952	Includes Kazinga channel joining Lake Edward to Lake George; tropical forests, swamps, grassland and volcanic craters; chimpanzee, elephant, antelope, lion, hippopotamus
UGANDA (*Cont.*)			
Aswa Lolim Game reserve	40 (25,600)	1959	Dry savanna, seasonal habitat of Uganda kob ranging from Murchison Falls National park adjacent
Kigezi Game reserve	200 (128,000)	1952	Grassland and tropical forest; plains and forest animals
Toro Game reserve	202 (129,300)	1946	Savanna and swamps on shore of Lake Albert; variety of wildlife, including elephant, buffalo, lion, hippopotamus
Bugungu Hippopotamus and Elephant sanctuary	183 (117,100)		On southwest boundary of Murchison Falls National park; special protection for hippopotamus and elephant
Debastien Game sanctuary	760 (486,400)	1958	Open plains, with characteristic wildlife
Elephant sanctuary	1,350 (864,000)		On southern boundary of Murchison Falls National park; special protection for elephant
Gorilla sanctuary	17 (10,900)		On Congo border, special protection for gorilla
Mt. Kei and Otze Crown Forest White Rhinoceros sanctuaries	250 (160,000)		Basin of the White Nile river, special protection for the rare white rhinoceros
ZAMBIA			
Kafue National park	8,650 (5,536,000)	1950	Kalahari sand (south), forests, floodplains, grasslands and marshes (north); eland, sable, roan, kudu, lechwe and other antelope, zebra, elephant, hippopotamus, rhinoceros
Isangano Game reserve	325 (208,000)	1957	Woodland and grassy plains, with perennial streams and Bangweulu swamps; only sanctuary for the rare black lechwe; elephant, buffalo, lion, various antelope
Kasanga Game reserve	150 (96,000)	1941	Papyrus swamp, bordered by grassland and woods; many wildlife species, including rare sitatunga and shoebill stork
Lavushi Manda Game reserve	580 (371,200)	1941	Wooded plateau and rocky hills; varied wildlife
Luangwa Valley Game reserve	5,000 (3,193,600)	1942	Flat valley of Luangwa river, with lower foothills; acacia woodlands, lagoons in river plain flood in rainy season; abundant and varied animal life, including elephant, rhinoceros, Thornicroft's giraffe
Lukusuzi Game reserve	1,050 (672,000)	1942	Wooded escarpments and plateaus; breeding ground for elephants; other animals
Lunga Game reserve	650 (416,000)	1951	Low forests and small grass plains; varied wildlife
Lusenga Plain Game reserve	340 (217,600)	1942	Woodlands and plains along Kalungwishi river; varied wildlife
Mweru Marsh Game reserve	1,210 (774,400)	1942	Papyrus and Phragmites marsh, merging into dry plains and woodlands; animal life abundant, including elephant, sitatunga, some black rhinoceros; myriad wading birds on mud flats in dry season
Sumbu Game reserve	780 (499,200)	1942	On southern shore of Lake Tanganyika, with river deltas, rocky ridges, woodland and small grass plains; many animals, especially elephant and blue duiker
Lochinvar ranch (private game reserve)			A large area, especially important to perpetuation of the red lechwe

of cattle herded by nomad Masai tribesmen. These cattle, sometimes diseased, usually undernourished and of little economic value, threaten to overgraze and destroy the range. In the mid-1950s, demands from the Masai, some of whom consider wild animals a competitive nuisance, threatened to cause drastic reduction of the national park with consequent destruction of the wildlife and its habitat. In 1956 the world-famous botanist and ecologist W. H. Pearsall studied the problem and recommended drastic changes in the government's plans. For the most part these changes were put into effect. In addition to the Serengeti and other national parks, Tanzania possesses game reserves where hunting is prohibited and other reserves where certain species are protected and where hunting is regulated.

Similar problems exist in Kenya and elsewhere in east Africa. The game department, the Royal National parks of Kenya and the Kenya Wild Life society have experimented with the concept of encouraging native participation in the benefits derived from national parks and reserves with a success that indicates this approach is feasible. Poaching, for biltong (meat), ivory and rhinoceros horn, is a serious threat to protected animals. Between 1946 and 1960 six national parks and six national reserves were established in Kenya. In 1961, three of the national reserves were transferred to African district councils under careful agreements in recognition of the growing interest of the native people in wild-

life preservation. Nairobi National park is close to the principal city and is famous as a placè where visitors can see lions at close range, giraffes, Thomson's and other gazelles, and a host of other mammals and birds beside the roads. It is too small to provide sufficient range for its wildlife, and herds of zebras and antelopes sometimes roam out of the park onto nearby farms, followed by lions which may commit depredations on livestock. Were it not for the supplementary habitat provided by the Ngong reserve nearby, the wild populations would find it difficult to perpetuate themselves. Tsavo National park to the south contains 8,034 sq.mi. of thorn scrub considered useless for human development but abounding with much wildlife. In its Mzimi pools hippopotamuses have lived for generations and may be observed swimming with escorts of fish in the crystal-clear water. A proposal to utilize these pools for a reclamation project was defeated by Mervyn Cowie, director of the Royal National park system in Kenya, and other conservationists. The Mount Kenya and Aberdare National parks were temporarily closed to the public because of the Mau Mau uprisings. The Marsabit reserve is one of the most beautiful regions of Africa and protects many species, some not found in the southern part of the country. There are also other reserves that support large wildlife populations. Three small national parks are historical and archaeological sites.

Murchison Falls National park, established in 1952 in Uganda, protects one of the famous waterfalls in Africa and is the habitat of many crocodiles, hippopotamuses, elephants, lions, leopards, antelopes and other species. Queen Elizabeth National park was also established in 1952 between lakes Edward and George. The view of the Ruwenzoris and other mountains across the lakes attracts many visitors, and the park itself is noted for its volcanic craters. Among other forms of wildlife there, this park supports a considerable population of chimpanzees. Its thousands of hippopotamuses have so greatly increased under protection that they are creating an overgrazing problem near the two lakes and the Kazinga channel which connects them. The solution to this problem seems to lie in the hippopotamus-cropping program now in operation. Uganda also has special reserves for the rare northern white rhinoceros and for gorillas and the large elephant sanctuary.

Equatorial Africa has suffered loss of animal life and vegetal cover, but the French authorities there were interested in preserving the most outstanding scenic areas and wildlife populations. The governments that replaced French administration endeavoured to continue this protection, although the change in political status caused some uncertainty about the future of the reserves. A number of nature reserves were established, of which the Vassako-Bulo reserve (375,000 ac.) protects wooded plains and arid forests in the Central African Republic. Adjacent to this reserve, and bounded also by three others, is the Parc National du Baminui-Bandoran (2,500,000 ac.); it has been suggested these areas be combined into a single national park. The Parc National Saint-Floris (40,000 ac.) is the sole habitat of the heronlike shoebill (*Balaeniceps rex*) in the Central African Republic. The Odzala National park in the Republic of Congo and the Parc Nationale de l'Okanda (475,000 ac. in Gabon) have been reserved in relatively unexplored regions. Most of these reservations are patrolled only by local inhabitants.

In Cameroon the Waza Game reserve protects rich animal life of plains species and thousands of aquatic birds. A 1,000-ac. isolated mountain forest was set aside in 1948 as the Monts Bamboutos reserve, and extensive areas are devoted to zoological reserves, game reserves and protected forest reserves where wildlife is safeguarded.

The Guinea Monts Nimba reserve (48,186 ac.), on the border between the Ivory Coast and Guinea, supports varied forest animal life, notably chimpanzees, and an abundance of epiphytic plants..

A large population of mammals and birds is protected in the Niokolo-Koba National park (617,800 ac.) in Senegal. The Parc National du "W" in Niger and a complex of contiguous reserves in Upper Volta and Dahomey, totaling 3,120,500 ac., protect many west African animals. The Banco National park (7,500 ac.) in the Ivory Coast contains a dense relict forest. In Mali, the Boucle du Baoulé National park is a mountainous, scenic forested area with abundant wildlife, bordered by large game reserves.

The extraordinary and unique animal life and vegetation of the island of Madagascar have been decimated over seven-tenths of the country by exploitation, but between 1927 and 1960 six nature reserves were established under the guardianship of the Musée National d'Histoire Naturelle in Paris. Under a decree of 1952, four similar reserves were created to protect especially dugongs, all species of lemurs, egrets and the endemic vegetation. In 1956 Jean-Jacques and Arlette Petter undertook an ecological study of the lemurs on the island, under the sponsorship of the Musée, the Institut de Recherche Scientifique de Madagascar, the Conseil National pour la Recherche Scientifique en France and the International Union for Conservation of Nature; this study added greatly to scientific knowledge and led to recommendations for additional reserves.

In Angola elands have increased markedly in the Quiçâma National park (2,461,440 ac.), as have other species. The beautiful rare giant sable antelope is especially protected with other wildlife in the Luando reserve. Black rhinoceros (150–200 in 1960) and Hartmann's zebras are abundant in the Moçâmedes reserve and inhabit others. The largest elephants in the world are found in Angola, and sizable herds are safeguarded in several of the reserves.

In the Somali Republic national parks and nature reserves have been established for the protection of animal life and vegetation, and laws have been enacted to ensure the survival of certain endangered species and to regulate hunting of others. Zoological and game reserves have also been established.

The two national parks in Morocco, the Toubkal National park and the Tazekka National park, are bordered by game reserves where hunting is regulated on a rotation basis. The land is arid but supports some protected forests.

National parks in Algeria are administered under strict policies to ensure perpetuation of natural ecological conditions. Visitors may see the varied wildlife of North Africa, including apes, foxes, several species of cats, reptiles and birds. The animals of this region were depleted by the ancient Romans to provide for their circuses. Tunisia has reserved two areas of interest to tourists, the Parc forestier d'Ain-Draham and the Forêt domaniale du Bou Kornine.

IV. ASIA

Although interest in national parks came later in Asia than in Africa, several countries have well-developed park systems. In Japan, for example, in spite of the large human population and need for agricultural and other economic exploitation of land, 7% of the total land area has been set aside as parks. Inspired by visits to the national parks of the United States in 1923 and 1924, Tsuyoshi Tamura influenced the Japanese government to enact a national parks law in 1931. By 1936, although funds were limited, 11 national parks had been established. After the close of World War II came recognition that the natural beauty of Japan represented one of its richest natural resources. New parks were created and their development for tourists and the enjoyment of the Japanese people was stimulated. In addition, quasi-national parks, administered by the prefectures, were established.

The Japanese visit their parks in great numbers. The parks also protect many religious shrines and temples, the most notable being the Grand Shrine of Ise in Ise–Shima National park. Fujiyama, in Fuji–Hakone–Izu National park, is among the most nearly perfect volcanic cones in the world; it is revered by the Japanese and is a major attraction for foreign tourists.

Japan possesses more crater lakes, or caldera, than any other country, and some of the largest in the world are in the national parks, those in Aso, Akan and Towada–Hachimantai being especially magnificent. The Japanese Alps are noted for gorges and waterfalls, for virgin forests and unusual wildlife. Equal in beauty are the rocky headlands and serene islands of the ocean coasts and borders of the Inland sea, with their forests and beaches and rocky islets inhabited by myriad nesting sea birds.

Any of the national parks may be visited from centres of popu-

TABLE V.—*Principal Parks and Reserves in Asia*

Name and location	Total gross area in sq mi. (approx. acreage in parens.)	Date established	Principal features
BURMA			
Nature Reserves (by Forest division)			
Kahilu (Thaton)	62 (39,700)	1928	Sumatran rhinoceros, serow, sambar, muntjac, barking deer, hog deer, musk deer; jungle birds
Kyatthin (Shwebo)	104 (66,600)	1941	Forests of Mt. Thaw; gaur, sambar, thamin, muntjac
Maymyo (Maymyo)	49 (31,400)		Barking deer, jungle fowl, partridge, peafowl
Mulayit (Thaungyin)	54 (34,200)	1936	Barking deer, muntjac, pig, tiger, leopard, birds
Pidaung (Myitkyina)	279 (178,400)	1918	East of upper Irrawaddy river; elephant, tiger, gaur and banteng (rare wild cattle), bear, leopard, barking deer, pig, jungle birds
Shwe-u-daung (east Katha and Mongmit)	126 (80,600)	1918	Sumatran rhinoceros, elephant, banteng, serow, sambar, tiger, leopard, jungle birds
Shwezet-taw (Minbu)	213 (136,600)	1940	Gaur, thamin, sambar, muntjac
CAMBODIA			
Angkor National park	41.3 (26,429)	1925	Monuments built by the Khmers, dense forest that partially covers the monuments
Kravanh Game reserve	1,091 (693,280)	1959	Varied wildlife
Koulen Promtep reserve	5,690 (3,641,490)	1960	Oxlike koupreys
Kirirom reserve	315 (201,708)	1962	Varied wildlife
Lomphat reserve	762 (487,777)	1964	Oxlike koupreys
Phnom Prich reserve	757 (484,446)	1960	Grassy plain; dipterocarp forests
CEYLON			
Gal Oya National park	98 (63,000)	1954	Skirts Gal Oya reservoir; evergreen and savanna forests, range of mountains on outer border; elephant, leopard, deer, sloth bear, etc.; remnants of ancient jungle tribe
Yala National park	91 (58,300)	1938	Coast line broken by lagoons; rocky hills rich in ancient ruins; forest and scrub
Hakgala reserve	4.4 (2,820)	1938	Representative collection of high-altitude plants
Wilpattu National park	252 (161,300)	1938	Mainly sandy area, a few rocky outcroppings; wildlife includes elephant, sambar, leopard and many species of birds
Ritigala reserve	5.8 (3,776)	1941	Mountain massif rising to 2,000 ft.; upper slopes support mixed vegetation of wet and dry zones; ancient Buddhist ruins
Wasgomuwa reserve	112 (72,036)	1940	Steep rocky hills
Yala Strict Nature reserve	111 (71,000)	1938	High forests and rocky hills; elephant, deer, leopard and other mammals and birds
INDIA			
National Parks			
Corbett (Uttar Pradesh)	125 (80,000)	1935	Jungle animal life, including elephant, tiger, leopard, sloth bear, several species of deer, sambar, goral, pig, wild dog, crocodile, python, many species of birds
Hazaribagh (Bihar)	150 (96,000)	1955	Tiger, leopard, bear, sambar, barking deer, etc.
Kanha (Madhya Pradesh)	98 (62,500)	1956	Easy view of large herds of hoofed animals, abundant wildlife, including gaur, sambar, axis deer, muntjac, etc.
Shivpuri (Madhya Pradesh)	61 (39,000)		Tiger, leopard, bear, sambar, spotted bull, four-horned antelope, Indian gazelle and varied bird life
Taroba (Maharashtra)	45 (28,800)	1935; 1956	Tiger, leopard, sambar, spotted deer
Wildlife Sanctuaries			
Dachigam (Kashmir)	55 (35,200)		Densely forested Himalayan mountain area north and east of the valley of Kashmir, between 9,000 and 13,000 ft.; primary refuge of the rare Kashmir stag; also musk deer, leopard, black bear, brown bear, boar and other wildlife
INDIA (*Cont.*)			
Wildlife Sanctuaries (*Cont.*)			
Gir (Maharashtra)	527 (337,300)	1900	On Kathiawar peninsula, arid desert with dry mixed deciduous teak forest surrounded by a belt of thorn scrub, intersected by narrow rivers; only remaining habitat of Asiatic lion; also chital, sambar, boar, chinkara, four-horned antelope, nilgai, monkey, leopard
Kaziranga (Assam)	166 (106,200)	1908	Tall elephant grassland bounded on north by Brahmaputra river; principal refuge of great Indian rhinoceros; buffalo, gaur, elephant, tiger, sambar, hog deer, swamp deer, boar, crocodile and bird life
Keibul Lamjao (Manipur)	20 (12,800)	1954	Established to protect only known wild population in India (100 in 1960) of the brow-antlered deer
INDONESIA			
G. Indrapura Nature reserve (West Sumatra)	49 (31,325)	1929	Wildlife; habitat of rare *Anaphalis javanica* plant
Gunung Loser Nature park (North Sumatra)	1,625 (1,040,250)	1934	Habitat of elephant, Sumatran rhinoceros, deer, tiger
Lautan Pasir Tengger Nature reserve (East Java)	20 (13,025)	1919	A sea of sand in the Tengger mountains
S. M. Bali Nature park (Nusa-Tenggara)	78 (50,000)	1941	Especially for protection of the "white starling" (*Leucopsar rothschildi*), tiger, deer and an ox indigenous to Bali
Sumatra-Selatan Nature park (South Sumatra)	1,394 (892,000)	1935	Sumatran rhinoceros, elephant, deer, serow, mouse deer, tapir, macaques, gibbons; giant *Rafflesia arnoldi*
Udjung Kulon–Panailan Nature reserve	161 (102,800)	1921	On two Javan islands; especially protects the very rare Javan rhinoceros; also tiger, chevrotain, barking deer; extraordinary vegetation
ISRAEL			
Arbel National park	5 (2,980)	1952	Mt. Arbel; isolated caves are breeding places for many birds, including the wall creeper; caves contain ruins of Hebrew fortress in Roman times
Jarmaq National park	35 (22,550)	1955	Peaks of Heidar, Adatir, and Hiram; picturesque valley of Leiman, rare and characteristic species of forest and maquis flora and fauna; ancient ruins
Mt. Carmel National park	40 (25,740)	1960	Abundant fossils; typical Mediterranean forest and scrub vegetation merging into higher pine forest; eagles and falcons
Elat Gulf Coral Reef reserve	0.5 (300)	1964	Coral reefs containing corals and coral fish; tropical sea fauna
Ein Gedi reserve	3 (1,750)		Oasis with distinctive flora not to be found elsewhere; abundant and varied fauna
Hula Swamp reserve	1.3 (800)	1957	Remnant of Huleh swamp with its typical flora and fauna; aquatic plants; nesting colony
Maagan Michael Fishing Ponds sanctuary	0.9 (600)	1959	Fish ponds full of nesting birds; many gulls and terns
Mt. Gilboa reserve	3 (1,950)	1962	Geological profile of Mt. Gilboa shows rocks of the Cretaceous and Eocene eras; transitional forest; Irano-Turanian vegetation
Mt. Meyron reserve	27 (17,500)	1965	Highest mountain area in the country; rare trees and flowers; varied fauna
Nahal Amud reserve	3 (1,875)	1965	Gradual change from typical Mediterranean plant life to steppe vegetation; nesting place of birds of prey, including the Bonelli eagle
Nahal Bezet reserve	3 (1,900)		Meandering river; many ferns; nesting places of birds of prey; small carnivores
Nahal Dishon reserve	5 (3,150)		Complete geological profiles of rocks typical of Galilee; rare plants; birds of prey; colonies of hyraxes
Nahal K'ziv reserve	4 (2,500)		Mountain gorge between cliffs; fine example of maquis woodland along slopes; nesting place of birds

Table V.—*Principal Parks and Reserves in Asia (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
ISRAEL *(Cont.)*			
Nahal Shorek reserve	4 (2,450)	1965	Typical geological and botanical section of Judean hills
Nahal Tabor reserve	4 (2,350)	1962	Steep springs in rocks of Eocene epoch; typical riparian vegetation; many acacias; gazelles
Ramoth Issashar reserve	16 (10,000)	1959	Slopes covered by annual grasses; many gazelles
Solelim Forest reserve	1.2 (740)	1962	Park land of Vallonea oak; climax of grey Eocene limestone soils
JAPAN *National Parks*			
Akan (Hokkaido)	338 (216,200)	1934	Active volcanoes, caldera lakes and hot springs, virgin conifer forests with rhododendron, azalea and birches, brown bear, snow rabbit and other wildlife, home of primitive Ainu people
Aso (Kyushu)	282 (180,500)	1934	Mt. Aso and vast atrio or sunken crater ringed with mountains in south, the Kuju plateau with many peaks in north, separated by grassland wilderness; forests and alpine meadows; wildlife
Bandai-Asahi (Honshu)	732 (468,700)	1950	Three disconnected sections: Mt Gassan volcano and Asahi range (north), Mt Iide, a granite peak with virgin forests and Mt. Azuma and Mt. Adatara volcanoes (central); Mt. Bandai (south) erupted in 1888 to produce some of world's largest dammed volcanic lakes; bear, monkey, serow in central section
Chichibu-Tama (Honshu)	188 (121,600)	1950	Spectacular scenic vistas of sedimentary ranges, rivers and dense dwarf bamboo moss forests, with virgin pine and spruce fir forests at higher elevations, several villages
Chubu Sangaku (Honshu)	655 (419,500)	1934	Forested Japanese Alps, with peaks, gorges and perpetual snows
Diasen-Oki (Chugoku)	123 (78,900)	1936	Mt Daisen and other peaks, with virgin pine and beech forests and snow-clad summits, religious shrines, Oki section includes 180 islands with many cliffs and grottoes, oldest shrine in Japan on Shimane peninsula
Daisetsuzan (Hokkaido)	896 (573,100)	1934	Three volcano groups and Ishikari range, with cliffs, gorges, waterfalls; vast alpine meadows and virgin conifer forests; brown bear, only Japanese habitat of crying "hare" (pika)
Fuji-Hakone-Izu (Honshu)	472 (302,200)	1936	Famous Fujiyama volcanic cone (3,776 m [12,388 ft]) with virgin forests, lakes and plains, Mt. Hakone area includes several volcanic peaks and hot springs, volcanic Izu peninsula noted for hot springs
Hakusan (Honshu)	183 (117,100)	1962	Small volcanic peaks around Mt. Hakusan, gorges, waterfalls, fossil forests; bear, antelope and other wildlife inhabit virgin forests, shrines
Ise-Shima (Honshu)	201 (128,600)	1946	Forested peninsula and coast line and island archipelago; Grand Shrine of Ise is national centre of religious worship; pearl farms in bays; bird life
Jo-Shin-Etsu Kogen (Honshu)	729 (466,800)	1949	Rugged Tanigawa range in north, with plateaus and volcanoes stretching south, including Mt. Asama, highest active volcano in Japan (2,542 m. [8,340 ft.]); Mt. Myōkō-Mt. Togakushi volcano complex to northwest; hot springs, forests; monkeys, antelopes
Kirishima-Yaku (Kyushu)	213 (136,500)	1934; 1964	23 volcanoes, some active, others with caldera lakes, hot springs; evergreen and azalea forests; several religious shrines, with giant cryptomeria trees
Minami Alps (Honshu)	138 (88,500)	1964	Popular mountainous park; rocky hills, cliffs and virgin forests
JAPAN *(Cont.)* *National Parks (Cont.)*			
Nikkō (Honshu)	543 (347,700)	1934	Scenic Nikkō volcanic area, peaks, lakes, waterfalls, marshes, virgin forests, abundant mammals and birds; several temples, including Toshogu shrine
Rikuchu Kaigan (Honshu)	45 (28,600)	1955	90 km (56 mi.) of coast line, cliffs, islands and beaches, pine and deciduous forests and subtropical vegetation; abundant bird life
Saikai (Kyushu)	94 (60,105)	1955	Dendritic coast line, Kujuku islands and Goto archipelago, subtropical forests, harbours
San-in Kaigan (Honshu)	35 (22,200)	1964	Sea-coastal park: inlets, capes and islands, cliffs, dens and grottoes, famed Tottori sand dune
Seto Naikai (Honshu)	255 (162,900)	1934	About 600 islands and coast land of Inland sea, fishing villages and farmlands; religious shrines; monkeys
Shikotsu-Toya (Hokkaido)	381 (243,800)	1949	Scenic volcanoes and caldera lakes, with virgin conifer forests and alpine vegetation; brown bear, Yeso squirrel, Japanese sable, birds, etc
Shiretoko (Hokkaido)	160 (102,200)	1964	Shiretoko peninsula, volcanic mountain ranges, Mt Iwo yama still active; virgin forests; wild bears, nesting sea birds; most primeval nature in Japan
Towada-Hachimantai (Honshu)	322 (206,000)	1936; 1956	Lake Towada, a double caldera lake, headwaters of Oirase river, and Hakkōda volcanoes, with primeval deciduous forests at lower elevations, conifers and alpine vegetation on slopes; Hachimantai section includes volcanoes and plateau, with hot springs
Unzen-Amakusa (Kyushu)	99 (63,300)	1934	Northern unit consists of plateau of Mt Fugen and other peaks, azaleas, boxtrees and deciduous forests; Amakusa section is an archipelago, with villages and historical relics of Christianity in Japan
Yoshino-Kumano (Honshu)	216 (138,200)	1936	Mt. Yoshino and Yoshino shrine, noted for cherry blossoms, rugged Omine mountain chain and Mt Odaigahara plateau stretch southward, with dense forests, gorges and cascades, the Kumano seacoast is bordered by innumerable rocky islets
Quasi-national Parks			
Abashiri (Hokkaido)	144 (92,400)	1958	Coast line, with shallow lakes and dunes; arctic vegetation; sea birds, seals; relics of Ainu culture
Biwa-ko (Honshu)	350 (224,100)	1950	Lake Biwa and surrounding Mt. Ibuki region
Sado-Yahiko (Sea of Japan)	178 (113,700)	1950	Volcanic Sado Island in the Sea of Japan
Yaba-Hida Hikosan (Kyushu)	420 (268,900)	1950	Volcanic area, adjacent to Aso National park; religious relics
Yatsugatake-Chusin-Kogen	154 (98,487)	1964	Volcanic mountain range, volcanic mesa, hot springs
JORDAN			
Azraq Desert Oasis National park	1,563 (1,000,000)	1966	Wildlife, migratory birds; desert castles, home of Bedouins; Azraq desert castle was used by Lawrence of Arabia
Qumran National monument and park	3.1 (2,000)	1966	Site encloses area of Dead Sea scrolls
MALAYSIA			
King George V National park	1,760 (1,126,400)	1938	Includes mountains, a wide plateau with unusual plants, many rivers and limestone outcrops; tropical rain forest; elephant, Sumatran rhinoceros, gaur, sambar, muntjac, Malayan tapir, bear, tiger, leopard
Taman Negara National park	1,677 (1,073,280)	1939	Virgin tropical forest, rivers with game fish; limestone outcrops
Krau Game reserve	252 (161,280)	1939	Virgin tropical forest; elephants, all species of deer, Malayan honey bear, Malayan tiger

TABLE V.—*Principal Parks and Reserves in Asia* (*Continued*)

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
MALAYSIA (*Cont.*)			
Sabah			
Kinabalu National park	275 (176,000)	1964	Surrounds and includes Mt. Kinabalu; area rich in flora and fauna; mountain intimately connected with folklore of Sabah
Sarawak			
Bako National park	10 (6,400)	1956	Coastal bays and coves near Cape Po; forest and open country; wild pig, mouse deer, monkeys, gibbon, bird life
Endau-Kota Tinggi Wild Life reserve	878 (561,900)	..	Protection of native animal life
Templar	5 (3,000)	1955	Limestone deposits; forests
NEPAL			
Chitawan Wildlife sanctuary	240 (153,600)	1956	Swampland and forest; great one-horned rhinoceroses, tigers, leopards, bears, gaurs, sambars, barking deer
Sukla Phanta Wildlife sanctuary	90 (57,600)	1964	Swampland, short-grass plain and forest; swamp deer, black bucks, spotted deer, barking deer, hog deer, tigers, leopards, elephants
PHILIPPINES			
National Parks			
Aurora (Luzon)	10 (5,800)	1937	Rolling terrain with dipterocarp forests and varied wildlife
Basilan (Basilan)	25 (15,900)	1939	Peaks and rough terrain, headwaters of six large rivers; virgin forest; varied wildlife
Bataan (Luzon)	121 (77,600)	1945	Verdant virgin forests on Bataan peninsula overlooking Manila bay; commemorates battle of Bataan; abundant wildlife
Bicol (Luzon)	20 (12,900)	1934	Scenic virgin dipterocarp forests on plateaus and river valleys; deer, wild boar, hornbill
Central Cebu (Cebu)	59 (38,000)	1937	Only extensive remaining virgin forest on Cebu; wildlife
Hundred Islands (Luzon)	7 (4,600)	1940	Coral islets, underwater coral formations, caves and fine beaches; Indian pygmy goose, Philippine bulbul, fish, etc.
Mayon Volcano (Luzon)	21 (13,500)	1938	Mt. Mayon (7,943 ft.) and rugged terrain, with grasslands and forests of dwarf trees; deer, boar, monitor lizard, many birds
Mt. Apo (Mindoro)	15 (9,800)	1936	Mt. Apo (9,691 ft.) volcano, highest in the Philippines, with moss and dipterocarp forests; monkey-eating eagle
Mt. Arayat (Luzon)	14 (9,200)	1933	Forested volcanic peak (3,564 ft.), with springs, rivers and small waterfalls
Mts. Banahaw-San Cristobal (Luzon)	35 (22,400)	1941	Rough forested country surrounding Mt. Banahaw (6,000 ft.) and Mt. San Cristobal (4,092 ft.); abundant wildlife
Mt Canlaon (Negros)	95 (60,700)	1934	Mt. Canlaon (8,000 ft.) and surrounding rugged forested terrain, with craters, hot springs; monkey, deer, boar
Mt. Data (Luzon)	21 (13,600)	1936	Pine-covered peak with ravines and waterfalls; varied wildlife
PHILIPPINES (*Cont.*)			
National Parks (*Cont.*)			
Mt. Isarog (Luzon)	39 (25,000)	1938	Rough forested region, with canyons, rivers and waterfalls; boar, deer, hornbill
Naujan Lake (Mindoro)	7.6 (4,900)	1956	Naujan lake and surrounding marshes and forests; principal breeding area of marsh birds; crocodile, sail-finned lizards
Quezon	38 (24,292)	1934	Largest forest park in Philippines; unbroken and extensive forest of numerous species; abundant wildlife; memorial statue of Pres. Luis Quezon
Sohoton Natural Bridge (Vizayan)	3.2 (2,100)	1935	Large natural bridge in forested rolling terrain, with limestone cave; deer, boar, monkey
Game Refuge and Bird Sanctuary			
Liguasan Marsh (Mindanao)	170 (108,600)	1940	Lush mangrove marsh; waterfowl nesting area, with other birds; monkey, deer, pig
SINGAPORE			
Bukit Timah reserve	0.3 (184)	1883	Forest lowland covering granite hill with 581 ft. elevation; many species of plants
Kranji reserve	0.08 (51)	1883	Climax mangrove marsh
Pandan reserve	0.56 (356)	1883	Pioneering and tidal mangrove plant associations
THAILAND			
Tung Slang Luang Natural park	494 (316,160)	1963	Virgin area of river, waterfalls and mountain scenery in northwest Thailand; tiger, leopard, deer, elephant
Khao Sam Roi Yord National park	23 (14,720)	1966	Large caves and jagged limestone mountain; many endemic plant species; goatlike serows are commonly found along mountain cliffs
Khoa Yai National park	837 (535,680)	1963	Mountains, rolling plateau, streams, waterfalls; big game animals; many birds
Phu Kadueng National park	134 (85,760)	1962	Streams, waterfalls, ponds; mountain with rolling grassland interspersed with pines; natural rock garden
TURKEY			
National Parks			
Karatepe-Arslantaş	16 (10,297)	1958	High elevation red oak and red pine forests, inhabited by roe deer, wolf, jackal, wild swine, marten and other animals; partridges and eagles; Hittite epitaphs, Phoenician and Roman mosaics and reliefs
Manyas Bird Paradise	0.2 (130)	1950; 1959	Grove of willows and shore line reeds on Lake Manyas, in Balikesir, nesting habitat for cormorants, egrets, spoonbills and glossy ibises
Soguksu	4 (2,525)	1959	Protects forested watershed adjacent to thermal spring resort of Kizilcahamam
Yozgat Pine Forest	1 (660)	1958	Representative of indigenous pine and oak forests of Anatolia; reforestation projects

lation in a single day; accommodations are excellent.

India's national parks protect some of the outstanding forest, jungle and mountain scenery of the subcontinent and an abundance of wildlife of many species. They are administered by the chief conservator of forests, the North East Frontier agency, or by other departments of the government; the Indian Board for Wild Life, founded in 1952, serves in a quasi-official advisory capacity.

Four of the many wildlife sanctuaries established in the respective states are of especial importance in the survival of rare endangered species. The Gir forest, northwest of Maharashtra, is the only remaining habitat of the Asiatic lion (*Panthera leo persica*). (This or a closely related race survived in Greece until A.D. 100. The lion is referred to 130 times in the Bible; it became extinct in Palestine about the time of the Crusades, but survived into the 20th century in Arabia, Iraq and Iran.) In India, lions inhabited much of the north and central portions until the 19th century, but the last recorded outside the Kathiawar peninsula was in 1884. Some 300 lions survive in the Gir forest, where they feed on other wild species and on livestock owned by the Maldhari, who have religious scruples against killing animals. After 1900 the lion was protected by decree of the many princes and the maharajah of the peninsula, and the animals have increased since.

The Kaziranga Wild Life sanctuary, in Assam, is the principal remaining habitat of the great Indian rhinoceros (*Rhinoceros unicornis*), which 500 years ago ranged over a large part of northern India and Nepal. Hunting, desiccation of fertile land by unrestricted livestock grazing, agriculture and fires, and the fantastic value placed on rhinoceros horn and other parts of the carcass for magical medicine, to detect poison in drinking potions and as an aphrodisiac, reduced the population drastically. Nearly all of these animals remaining in India (about 400 in 1960) are in sanctuaries and reserves, 260 of them in Kaziranga, where they are

safe from poaching and have become tolerant of human activity. In spite of royal restrictions on hunting in the Rapti valley of Nepal, poaching is a serious problem.

The Keibul Lamjao sanctuary is the only habitat of the brow-antlered deer (*Cervus eldi eldi*), feared to be near extinction before World War II but now holding its own locally under protection. The Kashmir stag (*Cervus elaphus hanglu*), the Himalayan relative of the European red deer and the American wapiti, was carefully protected by the maharajah of Kashmir prior to independence, and is safeguarded in the Dachigam sanctuary.

Indonesia has set aside over 100 nature reserves, ranging from small sanctuaries for bird life to large territories designed to protect all natural features and wildlife. The most important is the Udjung Kulon–Panailan Nature reserve at the western end of Java. This is the only known habitat of the Javan rhinoceros (*R. sondaicus*), a single-horned inhabitant of dense low tropical forest, of which possibly 24 to 48 individuals were surviving in the 1960s. Although these are given careful protection, scientists fear their numbers are too low to permit adequate reproduction and that the species may become extinct in the near future.

In Ceylon, under the Fauna and Flora Protection act of 1938, national parks and nature reserves are dedicated to complete protection of native vegetation and animal life; entry to them requires payment of a fee in the case of national parks or a written permit in that of the strict nature reserves. Intermediate zones mostly adjacent to the reserves serve as buffers between them and areas of human culture.

In addition, several sanctuaries give strict protection to vegetation and wildlife. Preservation of a number of Ceylonese animals is dependent on these reserved areas, including the hog deer, leopard, sloth, bear and especially the Indian elephant, which may cease to exist as a wild species outside the reserves. (F. M. PD.)

V. GREAT BRITAIN

National Parks.—The tenth national park in England and Wales was established in 1957 in the Brecon Beacons. A total area of over 5,200 sq.mi. was then covered by national parks. They are: the Lake District National Park, the Peak District, Snowdonia, Dartmoor, the Pembrokeshire Coast, the North York Moors, the Yorkshire Dales, Exmoor, Northumberland (a part of the county) and the Brecon Beacons. National parks in England and Wales are set up under the National Parks and Access to the Countryside act which received the royal assent in Dec. 1949 and established a National Park commission whose duties include selecting areas it considers suitable to become national parks.

These are extensive areas of country possessing a marked degree of natural beauty and good opportunities for open-air recreation, which have been designated by the commission and confirmed by the minister of housing and local government, in order to preserve and enhance their characteristic beauty and to improve their facilities for enjoyment by the public. The provisions of the 1949 act relating to national parks did not extend to Scotland, but those relating to nature conservation extended to all parts of Great Britain and are the responsibility of the Nature Conservancy, as explained below.

The passing of the 1949 act was the culmination of a campaign dating from the second half of the 19th century, fought by various voluntary organizations which strived to preserve the countryside and its wildlife and to secure public rights of access to mountain and moorland. These included the Commons, Open Spaces and Footpaths Preservation society, the National Trust, the Society for the Promotion of Nature Reserves, the Ramblers Association, the Royal Society for the Protection of Birds and the Councils for the Preservation of Rural England (C.P.R.E.) and Wales.

In the early 1930s there was a growing public interest in the idea of creating national parks, and the efforts of the voluntary organizations were co-ordinated by the formation in 1935 of the C.P.R.E.'s standing committee on national parks, which made representations to the government to take effective action. Committees were appointed by the government of the day to consider the question of national parks and other relevant problems concerning the countryside, notable reports of this period being those of the Addison committee (Cmd. 3851) in 1931 and the Scott committee (Cmd. 6378) in 1942. It was by now generally realized that a further and more comprehensive investigation was needed.

In May 1945 a report on national parks (Cmd. 6628) by John Dower—an architect and a great authority on the landscape—was presented to parliament by the minister of town and country planning and published for information and as a basis for discussion. Later the same year the government appointed a committee under the chairmanship of Sir Arthur Hobhouse to consider the Dower report and to make recommendations.

The report of the Hobhouse committee (Cmd. 7121), published in 1947, recommended the setting up of a National Parks commission and the creation of 12 national parks. This report formed the basis of the legislation of 1949, but the passing of the Town and Country Planning act in 1947, which transferred planning control from district councils to county councils, had a profound effect on the degree to which the Hobhouse committee's recommendations were accepted.

The National Parks commission does not itself administer the national parks, as was recommended in the Hobhouse report; apart

TABLE VI.—*National Parks in Great Britain*

Name and location	Total gross area in sq.mi. (with approx. acreage in parens.)	Date established	Principal features
Peak District (mainly Derbyshire but including parts of Cheshire, Staffordshire, West Riding of Yorkshire and Sheffield)	542 (346,900)	1951	Gritstone moorland of the south Pennines in central England; limestone uplands, wooded dales
Lake District (Cumberland, Lancashire and Westmorland)	866 (554,200)	1951	Spectacular mountain scenery with lakes and fells in northwestern England; interesting wildlife, rock climbing, wooded valleys
Snowdonia (Caernarvonshire, Denbighshire and Merioneth)	845 (540,800)	1951	Snowdon and the Cambrian mountains in north Wales and Cader Idris. Cwm Idwal and other National Nature reserves
Dartmoor (Devon)	365 (233,600)	1951	Plateau of wild moorland in southern England; tors, river valleys and hanging oak woods; prehistoric relics
Pembrokeshire Coast (Pembrokeshire)	225 (144,000)	1952	Rocky coast line and the Prescelly mountains in south Wales. Norman castles, prehistoric sites and island bird sanctuaries
North York Moors (North Riding of Yorkshire)	553 (353,900)	1952	Open moorland plateau extending from the plain of York to the northeast coast of England; medieval castles and abbeys
Yorkshire Dales (North and West Ridings of Yorkshire)	680 (435,200)	1954	Wide, sweeping upland moors, cut by deep pastoral valleys, in the central Pennines of England; caves, castles and prehistoric and Roman sites
Exmoor (Devon and Somerset)	265 (169,600)	1954	Heather moorland, once a Norman Royal hunting forest with a fine sea coast on Bristol channel; prehistoric camps
Northumberland (Northumberland)	398 (254,700)	1956	Cheviot hills on Scottish border of England and Hadrian's wall; moorlands, fells, rivers and forests, ancient British and Roman camps
Brecon Beacons (mainly Brecknockshire, but including parts of Carmarthenshire and Monmouthshire)	515 (329,600)	1957	Northward-facing escarpment in south Wales rising nearly to 3,000 ft., with moorland on southern slopes, and many rivers; caverns, prehistoric and Roman remains; Carreg Cennen castle

from its executive powers to select areas for such designation, the commission's duties are mainly advisory. The national parks are administered by special park planning authorities set up under the 1949 act, on which sit a proportion of members appointed upon the nomination of the minister of housing and local government by reason of their special concern with the national aspect of the parks.

Within national parks the normal life of the area goes on; the land is not sterilized, neither does designation affect in any way the existing ownership of the land. The park planning authorities control development just as county councils do elsewhere throughout England and Wales, but in doing this they pay special regard to the fact that the park is one of Britain's finest landscapes which stands in need of preservation.

Other duties of the park planning authorities include the drawing up of annual programs to accomplish the purposes of the parks. And they have special powers. They may, for example, make arrangements to provide accommodations, meals and places of refreshment where the existing facilities are inadequate. They may lay out caravan (trailer) sites and parking places, and arrange for facilities for sailing, bathing, boating and fishing. For approved facilities of this kind, the government pays grants up to 75% of the total expenditure. Grants are also payable for approved measures taken to preserve and enhance the natural beauty of the parks, such as the removal of disfigurements, the restoration of derelict land and the planting of trees. (L. J. W.)

Nature Reserves.—Nature reserves in Great Britain may be traced back as far as the medieval royal forests which had nothing to do with silviculture but were managed under strict legislation designed to secure the maximum protection, cover and food for beasts and birds of the chase. In modern times a few small bird sanctuaries were created informally during the 19th or early 20th century and from 1894 there was statutory power to establish bird sanctuaries, although most of the orders made for this purpose were not actively enforced.

During World War I a comprehensive list of proposed nature reserves was drawn up for the board of agriculture but no official action was taken until the appointment by the planning ministers in 1945–46 of the two Wildlife Conservation Special committees for England and Wales and for Scotland, in connection with the National Parks committees. The reports of these committees resulted in the creation by royal charter in 1949 of the Nature conservancy as a crown body under the supervision of a committee of the privy council with the objects of advising scientifically on conservation, of operating nature reserves and of undertaking scientific research.

The program of national nature reserves includes areas in England, Scotland and Wales ranging in size up to approximately 40,000 ac. and forming the best available examples of natural or seminatural habitats including arctic-alpine vegetation, bogs, woodlands (both deciduous and coniferous), fens, grasslands, inland waters, dunes, salt marshes, expanses of shingle, sea cliffs and islands.

Among the largest nature reserves are the Cairngorms Nature Reserve in the eastern Scottish Highlands (39,689 ac.), the Inverpolly Nature Reserve in the western Highlands (26,791 ac.), the Moor House Nature Reserve in the Westmorland Pennines (10,000 ac.) and the Beinn Eighe Nature Reserve in the western Scottish Highlands (10,450 ac.).

British nature reserves inevitably differ from those in less developed countries in being mostly smaller, more frequented and farther from their primitive state. The majority are open to public access but several are closed except to permit holders. Some are primarily selected as "living museums" to conserve picked examples of natural communities of plants and animals or to serve as refuges for rarities. Others are partly or mainly used as open-air laboratories on which experiments are conducted into the effects of climate and drainage, or of different types of management treatment such as grazing, planting, fencing and control of burning. Comprehensive records are kept of the elements and changes in the animal life and vegetation and of the enrichment or impoverishment of soils.

The broad purpose of the conservancy's nature reserves is to provide suitable and secure arrangements for long-term studies of the natural resources of Great Britain and to preserve for future generations the best possible range of examples of the natural vegetation and animal life. These official nature reserves are supplemented by a somewhat larger number of unofficial reserves managed by the Society for the Promotion of Nature Reserves, the Royal Society for the Protection of Birds, the National trust, the National Trust for Scotland and various regional or county trusts, of which the Norfolk, Yorkshire and Lincolnshire Naturalists' trusts are leading examples. In addition the conservancy has notified to local planning authorities more than 1,700 sites of special scientific interest over which the Nature conservancy must be consulted before permission for development is given.

(E. M. N.)

VI. EUROPE

Plato and other philosophers of antiquity recognized the desirability of a harmonious relationship between man and his natural environment, but the ancient civilizations did not develop the concept that nature itself is worth preserving. Royal prerogatives, from early times through the middle ages and into modern times, often restricted hunting of certain species of animals to nobles, protected eagles and hawks for falconry and closed extensive areas to trespass by commoners. These were feudal measures to benefit the oligarchy, although they resulted in some measure of nature protection.

Some of these preserves were maintained for centuries and saved primeval regions and wildlife species. The aurochs, ancestor of domestic cattle, protected by royal decrees, survived in Poland until 1627. In the same country, all hunting was prohibited in the Belovezh forest in the 17th century and only by this protection was the wisent, the European bison, perpetuated to modern times.

The Renaissance brought an interest in natural philosophy and with it the stirring of an appreciation of nature and its processes. Local communities began to restrict exploitation of the resources of economic importance, to control woodcutting and grazing, and even to preserve natural areas intact, as in the case of the Bois de la Haye, in Holland, in 1576. During the mid-19th century the German naturalist Alexander von Humboldt conceived the idea of establishing natural monuments for preservation of natural ecology. It was not until the 20th century, however, and mainly after World War I, that European nations undertook extensive establishment of national parks and nature reserves in the modern sense. By 1960, almost every European country had set aside some areas to protect scenery, natural environment and wildlife.

In Austria, for example, the *Länder* have promulgated laws and ordinances which provide varying degrees of protection to a large number of nature reserves ranging in size from a few acres to many square kilometers. These include outstanding scenic mountain areas, forests, lakes, geological formations and relic habitats of rare plant associations as well as important wildlife habitat. A 200-m. zone is protected from exploitation along a number of scenic highways, and green belts have been established around certain cities.

In France, part of the Forest of Fontainebleau, near Paris, was established as a nature reserve in 1953. The Pelvoux park, established in 1923, is a scenic alpine area where, in spite of wars, many wild animals have survived, notably the chamois. The Camargue reserve, established in 1927, is a world-famous ornithological sanctuary and research area, where flamingos, herons, avocets and other marsh birds breed in numbers and unusual plant associations occur.

A considerable number of nature reserves and bird refuges have been established in Belgium by the citizens' associations Ardenne et Gaume, Reserves ornithologique de Belgique, and De Wielewaal, to protect scenic features, habitat of nesting and migrating birds, plant associations and other natural features. They are relatively small but serve important conservation purposes. Two official nature reserves were established in 1957.

Nature protection has been practised in Denmark since 1805 and in Czechoslovakia since 1838, but modern nature reserves in both

TABLE VII.—*Principal Parks and Reserves in Europe*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
AUSTRIA			
Karwendel reserve	280 (179,200)	1943; 1947	Alpine and subalpine vegetation and animal life in limestone region of the Karwendel mountains of Tirol
Hohe-Tauern Scenic reserve		1942	The valleys from the Gerlostal to the Raurisertal, Gasteinertal, Kleinarltal and the upper reaches of the Grossarltal
Neusiedler See and Seewinkel Scenic reserve		1940	On the Danube plain at the Hungarian border; source of major rivers; notable bird life; hydrobiological research station
BELGIUM			
Lesse et Lhomme National park	4 (2,500)	1954	Protects scenic region with unusual geological formations
Hautes Fagnes Nature reserve	14 (9,125)	1957; 1958	Swamps, peat bogs and Ardennes plateau with glacial and subalpine plant associations, ecological research station
Westhoek Nature reserve	1.3 (823)	1957	Sand dunes; beach research; maritime flora
BULGARIA			
Belogradchishki Skali National park	31 (19,768)	1949	Natural rocky formation cut by two rivers, two artificial lakes; conglomerate formations resemble animals and people
Kailuka National park	3.3 (2,149)	1939	Narrow river valley surrounded by sheer limestone rocks; hilly area planted with pitch pines, sycamore trees, acacias, walnut trees
Ropotamo National park	3.2 (2,093)	1962	Forest in a periodically flooded area, ash trees, brushwood, grasses, water lilies; nesting birds and wild flowers
Vihren National park	26 (16,645)	1962	Marbled limestone, glacial valleys, forested; rare alpine grasses
Vitocha National park	25 (16,000)	1933	In the massif of Rila, near the Yugoslavian border, with forested mountains and a peat bog noted for its wild flowers
CZECHOSLOVAKIA			
Krkonoše and Jizerské Hory	460 (294,400)	1955	Glaciers, alpine meadows, peat bogs, hot springs, plants and wildlife; 150 sq.mi. classified as a strict nature reserve
Dobročský Prales reserve	0.2 (128)	1913	Primeval forest
Mohelenská Hadoová reserve	0.2 (128)	1952	Rocky serpentine hillside; dwarf plant forms
Velký a Malý Tisý reserve	2.5 (1,600)	1955	Ponds with water and marsh flora; nesting ground of water birds
Žofínský Prales reserve	0.4 (256)	1838	Protected primeval forest with typical mountain flora
Sumava Protected Landscape region	723 (462,720)	1963	Extensive forest area along southwestern border of Bohemia; 10 nature reserves within this area; evidence of glacier activity from Ice Age; extensive peat moors; relict species of flora and fauna
Tatranský Národní park	463 (296,320)	1949	High mountain scenery, on Polish border, with glaciers, forests, endemic plants; chamois, bear and other wildlife
DENMARK			
Skallingen	12 (7,700)	1939	Largest nature reserve in Denmark, on the west coast of Jutland, with dunes, marshes and a research laboratory
Tipperne og Klaegbanken	3.5 (2,200)	1895; 1936	Several islands on west coast of Jutland protect thousands of nesting shore birds, terns and other birds, also migrant species; ecological laboratory
FINLAND			
National Parks			
Linnansaari	3.1 (2,000)	1956	Group of about 20 islands in Lake Haukivesi; osprey colony; rare plants; access by boat
Pyhähäkki	3.9 (2,500)	1956	Virgin pine forest, swamps and peat lakes
Oulanka	41 (26,450)	1956	Wild terrain along the Oulou-joki river and tributaries
Pyhätunturi	11.6 (7,400)	1938	Pyhatunturi is the most southerly arctic mountain in Finland, a traditional sacred place for Lapps
FINLAND (*Cont.*)			
National Parks (Cont.)			
Pallas-Ounastunturi	193 (123,500)	1938	Lapp fjord country, with arctic mountains, peat lands and forests
Lemmenjoki	149 (95,100)	1956	Lemmenjoki river drainage; mountain gorge and lakes
FRANCE			
National Parks			
Vanoise	208 (133,440)	1963	Mountainous region near Gran Paradiso in Italy; alpine fauna and flora
Port-Cros	58 (37,070)	1963	Island of bush, forest and subforest
Reserves			
Camargue Nature reserve	36 (23,140)	1928	Zoological refuge on delta of Rhône river, noted for nesting flamingos; ecological research
Forest of Fontainebleau	6.3 (4,006)	1953	Protects natural beauty and biological features in environs of Paris
Pelvoux park	85 (54,430)	1923	Alpine region, with chamois and other wildlife
WEST GERMANY			
Naturschutzpark Hoher Vogelsberg (Hesse)	84 (53,750)	1958	Volcanic uplands, one-third covered by copper beech and spruce forest; balance agricultural
Naturschutzpark Lüneburger Heide	78 (50,000)	1909	Established to protect and restore the landscape and native heath; spur ridges extend over a wide plain of alluvial sands, with valleys and streams, oak, birch and pine forests
Naturpark Münden (Lower Saxony)	76 (48,868)	1951	Hilly area with volcanic peaks, copper beech and spruce forests, and open pastures
Naturpark Pfälzer Wald	654 (418,250)	1958	A sandstone plateau with deep valleys, the largest continuous forest in the Federated Republic. 120 villages are scattered in the area
Naturschutzpark Siebengebirge (Cologne)	33 (21,250)	1922; 1930	Many volcanic mountains and limestone formations; forests and wildflowers, including orchids. Mining, destruction of plants (except removal of timber under permit) and disturbance of wildlife prohibited
Naturpark Südeifel	42 (26,750)	1958	Plateau area in mountainous Eifel region on the Luxembourg frontier; one half mixed deciduous and conifer forest, the remainder mostly farmland; wildlife abundant
GREECE			
National Parks			
Grove of the Daphni Monastery	0.55 (350)		Outside of Athens; wine festival in the park every September
Wooded area at Mt. Olympus	47 (30,000)	1938	Includes Olympus mountain peak, mythological home of the gods; light forests of pine, beech and broad-leaved evergreens
HUNGARY			
Tihany National park	2.7 (1,700)	1952	Volcanic area, with 100 rock cone geysers and lakes; Bronze Age ramparts and 12th century monk cave dwellings
Kis Balaton reserve	5.5 (3,508)	1951	Reed marsh rookery of egrets, ibises, spoonbills and other herons; entry to the area is by permit only
Aggtelek-Jósvafő	3 (1,970)	1945; 1958	Limestone cavern, 15 km. (9 mi.) long, with large chambers and formations, extending into Czechoslovakia, where it is also protected
Szalajkavölgy reserve	2.2 (1,395)	1955	Centre of paleolithic culture in the Bükk mountains
ICELAND			
Thingvellir National park	15.4 (9,880)	1928	Postglacial lava plain with deep fissures; Öxará river; meeting place of ancient *althing* (parliament) of chieftains from A.D. 930
Eldey Nature reserve	0.006 (3.7)	1940; 1960	Rookery of gannets; last two living examples of the now extinct great auk were found here

TABLE VII.—*Principal Parks and Reserves in Europe* (*Continued*)

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
IRELAND			
Bourn Vincent Memorial park	17 (10,550)	1932	Mountains and lakes of Killarney, with farm and forest lands; last herds in Ireland of European red deer; Japanese deer introduced
North Bull Island Nature reserve	5 (3,200)	1931	Sandy island; sanctuary for migratory and wintering birds
ITALY			
Abruzzo National park	113 (72,000)	1923	High mountains in Marsica region in central Italy, with cirques, moraines and peaks rising to 2,247 m. (7,372 ft.); thick pine and deciduous forests; chamois, bear, roe deer and other wildlife
Circeo National park	29 (18,400)	1935	Promontory, southeast of Rome, containing maritime forest of Terracina, coastal dunes and associated animal life and vegetation
Gran Paradiso National park	240 (153,940)	1922	Scenic mountain ranges, rising to 4,061 m. (13,323 ft.), in northwest Italy, with extensive glaciers, alpine vegetation and animal life
Stelvio National park	368 (235,600)	1935	Magnificent alpine region on Swiss border, with several life zones and their characteristic plant associations and forests, with crags rising 3,899 m. (12,792 ft.); glaciers; stag, chamois, roe deer, bear and other wildlife
NETHERLANDS			
Hoge Veluwe National park	23 (14,700)	1935	Forests, heather with red deer and mouflon (introduced)
Kennemerduinen National park	5 (3,064)	1950	Dunes and bird life
Texel Island Nature reserve	5.5 (3,500)	1909	Terns and other sea birds
Boschplaat reserve	17 (10,870)	1924	On island of Terschelling; dunes and seacoast; sea birds and waders
State Game reservation	11.6 (7,400)	1955	Woodland; red deer, roe deer, wild boar
Kobbeduinen reserve	9.2 (5,900)	1955	On island of Schiermonnikoog; sea-dunes
De Wieden reserve	7.4 (4,750)	1934	Water and marshland; rich interesting flora; water and marsh fowl
NORWAY			
Kong Karls Land reserve (Spitsbergen)	200 (128,000)	1939	Arctic islands; polar bear reserve
Gutulia area (Hedmark)	3 (2,000)	1957	Primeval mountain forest of Norway spruce and Scots pine; bogs
Ormtjernkampen area (Oppland)	1.8 (1,125)	1956	Primeval mountain forest of mainly Norway spruce
Vaggetem area (Finnmark)	2 (1,250)	1910–11	Primeval forest of Scots pine
National Parks			
Børgefjell (Nordland and Nord-Trondelag)	382 (247,000)	1963	Alpine and subalpine area, numerous lakes and rivers; birdlife especially interesting
Rondane (Oppland and Hedmark)	222 (142,080)	1962	Alpine area, 10 peaks more than 2,000 m. (6,562 ft.); interesting geology; popular skiing area
POLAND			
National Parks			
Babia Gora	6 (4,105)	1954	Remnants of ancient Carpathian forests in the Babia Gora range, part of the West-Beskidy mountains in southern Poland and extending into Czechoslovakia
Bialowieza	20 (12,683)	1947	Best preserved part of the primeval forest of Bialowieza; heights of trees up to 57 m. (187 ft.), some hundreds of years old; largest breeding centre of rare European bison
Kampinos	84 (55,235)	1959	Forested dune area, near Warsaw; prehistoric dwellings; elk and a numerous heron colony
Karkonoski	22 (13,773)	1959	Northern slope of Karkonosze mountain range in southeast Poland on Czechoslovakia border, with glaciated peaks, lakes, waterfalls and forests
POLAND (*Cont.*)			
National Parks (*Cont.*)			
Ojcow	6 (4,139)	1956	Picturesque Pradnik and Saspowka valley; notable rock formations; large caverns; primitive forests; endemic Ojcow birch; great eagle owls, water ouzels, bats, historical castles
Pieniny	10 (6,692)	1932; 1954	Picturesque lime mountain range; numerous valleys; Dunajec river gorge; entire area a forest, many endemic and rare plants; deer, lynx, great eagle owl, rare insects
Slowinski	69 (44,479)	1966	Migratory birds; moving dunes; dwarf pine tree forest
Swietokrzyski	23 (14,935)	1950	Main Swietokrzyski mountain range; beech and fir forests; areas of scattered rocks mark primitive nature
Tatra	84 (53,890)	1954	Polish Tatra mountains, highest part of the Carpathians; numerous highland lakes and caverns; chamois and marmot
Wielkopolska	21 (13,307)	1957	Moraine forests on Warta river; post-glacier lakes and wildlife
Wolinski	18 (11,500)	1960	Shores of Wolin Island; glaciers, island cliffs with forests; dune plants; rare bird species; white-tailed eagles, great eagle owls, ospreys
RUMANIA			
Retezat National park	50 (32,125)	1935	Glaciated summits 2,572–8,205 ft. (784–2,501 m.) high; conifer forests; chamois, lynx, bear, raptorial birds
Cetăţile Ponorului reserve	1.8 (1,142)	1955	Three massive peaks and a magnificent scenic portal; caves with underground rivers; the wild Galbena valley; ancient beech forests
Forêt et Lac de Snagov reserve	6.6 (4,292)	1952	Relic of ancient mixed hardwood forest on Danubian plain; lake
Les Clairières à Narcisses reserve	1.5 (964)	1957	Vast glades of *Narcissus stellaris* in an oak forest at foot of Mt. Fafaras
Pietrosul Mare reserve	10 (6,672)		Glacial relief; glacial lakes; alpine flora; chamois
Tourbière "Tinovul Mare" reserve	2.6 (1,668)	1955	Sphagnum peat bog with many rare plants; pine and birch forests
Reserves of the Danube delta	129 (82,780)	1963	Great variety of water fowl; pelicans, egrets, herons, swans, avocets, geese, ducks
SPAIN			
National Parks			
Covadonga (Oviedo and León)	65 (41,820)	1918	Covadonga mountains; pasture land, abundant chamois; also, mountain lions, bears, numerous birds; forests of beech, oak, sycamore, ash, hazel; many rivers cross the park
Ordesa (Huesca)	8.4 (5,375)	1918	Ordesa valley in the Pyrenees; Arazas river with three waterfalls; pine forests, variety of plant life; pheasant, falcon, trout, chamois
Teide (Isla de Tenerife)	42 (27,182)	1954	Teide and Gran Circo mountains, exotic vegetation; volcanic formations; unique flowers
Caldera de Taburiente (Isla de la Palma)	13.5 (8,649)	1954	Roque de los Muchachos mountains; volcanic formations; variety of exotic plant life; thorny plants; old laurel forest; goats
Aigues Tortes and Lake San Mauricio	41 (25,946)	1955	Sierra de los Encantats mountains in the Pyrenees; numerous lakes; black pine forest; wild boar, chamois, white partridge, trout
SWEDEN			
National Parks			
Abisko	29 (18,560)	1909	High mountain scenery near the arctic circle; most of park rich mountain vegetation; reindeer, bear, lynx, golden eagle, snowy owl, other wildlife; Lapp settlements
Muddus	195 (124,800)	1942	Coniferous woodland and bogs; virgin pine forests, abundant wildlife

TABLE VII.—*Principal Parks and Reserves in Europe* (*Continued*)

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
SWEDEN (*Cont.*) *National Parks* (*Cont.*)			
Padjelanta	788 (504,100)	1962	Wide mountain plain situated around lakes Virihaure and Vastenjaure; valuable botanical region with species not found elsewhere in Sweden; many large wild animals; rich bird life; summer pasture for reindeer; summer quarters of Lapps
Sarek	735 (470,490)	1909	Largest wild area in Europe; high mountain region, extremely rough country, dense willow thickets, large glaciers; rich fauna; delta of the Rapaalven
Stora Sjöfallet	48 (31,000)	1909	Extensive mountain region around mountain lakes in the Stora Lule alv river system; many different types of topography, flora and fauna
SWITZERLAND			
Swiss National park	5,025 (3,216,000)	1914; 1959	An alpine sanctuary, primarily to serve scientific research; high Alps from 1,500 to 3,173 m. (4,921–10,410 ft.); magnificent scenery; endemic plants; chamois, red deer, roe deer, ibex (introduced 1920) and other wildlife
UNION OF SOVIET SOCIALIST REPUBLICS *Russian S.F.S.R.*			
Altai (Gorno-Altai autonomous *oblast*)	3,575 (2,287,800)		Scenic taiga of fir, cedar and larch, rising to alpine tundra; many wildlife species, including snow leopard, wild dog, ibex, musk and roe deer, bear and others
Astrakhan (Astrakhan *oblast*)	295 (189,075)	1919	Protects nesting area of coot, sheldrake, pelicans, herons and spoonbills, and molting grounds for myriad waterfowl, on Volga delta; fish are abundant; hydrological research
Barguzin (Buryat A S.S.R.)	970 (620,500)	1926	Protects mountainous terrain of northern Transbaikalia and especially the dark sable inhabiting its forests; seal rookeries on the Ushkany Islands
Bashkir (Bashkir A.S.S.R.)	313 (180,000)	1958	Mountain and steppe forests of southern Urals; varied wildlife; Kapov cave contains primitive drawings
Caucasus (Krasnodar *krai*)	984 (629,500)	1924	Beech and conifer forest with rhododendrons, rising to alpine meadows in western Caucasus; mountain goat, chamois, deer; re-established bison roaming at liberty
Darwin (Vologda and Yaroslavl *oblasti*)	432 (276,600)	1945	Broken pine forest, sphagnum marshes and heather; elk, bear, lynx, upland birds, shore birds, waterfowl; established to study ecological changes in connection with building of Rybinsk reservoir
Ilmen (Chelyabinsk *oblast*)	125 (80,000)	1920	In honour of Lenin; pine and birch forest; stretches of steppe covered with feather grass; preservation and study of geology; minerals and semi-precious stones
Kandalaksha and Lapland reserve (Murmansk *oblast*)	385 (245,200)	1932	Arctic tundra and mountainous terrain along Murmansk coast; vast numbers of alcids and other sea birds; elk, brown bear, lynx and wolverine on Veliki Island; islands in Kandalakshski gulf are covered with spruce, pine, and birch forests; seals along shore; Lapland includes mountain tundra, established to protect wild reindeer and beavers
Kedrovaia Pad (Primorski *krai*)	60 (44,200)	1916	Mixed forest of Mongolian oak, Manchurian fir, cedar, Amur cork and other far eastern trees; sika (*Cervus nippon*), roe deer, musk deer, boar, leopard, bear, marten and other wildlife
Khekhtsir	174 (111,620)	1963	Manchurian vegetation; Korean cedars, firs, Mongolian oaks, Manchurian ash trees; grapes, lemons; wild boars, roe deer, foxes, other small mammals
U.S.S.R. (*Cont.*) *Russian S.F.S.R.* (*Cont.*)			
Khingan	325 (144,000)	1963	Bears, Manchurian hares, game birds; mountainous cedar taiga; birch, aspen
Komsomol	124 (79,534)	1963	Mountains on banks of Amur river; Korean cedars, lindens, alder trees; brown bears, wolverines, elk
Mordvinian (Mordvinian A.S.S.R.)	118 (75,250)		Pine forests with some deciduous trees; varied wildlife
Oka (Ryazan *oblast*)	88 (56,500)		Mixed forests and flood-plain marshes and lakes of Pra river
Pechora–Ilych (Komi A S.S.R.)	2,790 (1,785,750)		Central taiga of spruce and pine; mountain taiga of conifers, including stone pine; sable, reindeer, capercaillie; domestication of elk
Prioksko–Terrasny (Moscow *oblast*)	19 (12,000)		Pine and broad leaved forests, steppe vegetation; breeding of bison
Sikhote-Alin (including Sudzukhe reserve) (Primorski *krai*)	2,342 (1,499,000)		Broad-leaved and conifer forests, including Amur lime, Korean pine, Yeddo spruce, Khingan fir and other species; tiger, leopard, baribal bear, Amur bear, Manchurian deer and other wildlife; Sudzukhe includes southern vegetation of Manchurian type; punctate deer, mountain antelopes
Stolby (Krasnoyarsk *krai*)	184 (117,500)		Mountain taiga belt, mixed pine and larch forests; pillarlike rock formations
Suputinka (Primorski *krai*)	62 (39,750)		Border zone between Manchurian cedar forests and mixed deciduous spruce and fir forests; varied wildlife
Teberda (Stavropol *krai*)	361 (231,000)		Conifer and beech forests, with rhododendrons, rising to alpine meadows on north slope of greater Caucasus mountains; a major tourist attraction
Tsentralno–Chernozemny (Kursk and Belgorod *oblasti*)	16 (10,500)		Three areas of virgin steppe, with oak groves
Tsentralno–Lesnoi (Kalinin *oblast*)	82 (52,750)		Mixed forests and meadow steppe; bear, marten, capercaillie
Volga–Kama (Tatar A.S.S.R.)	30 (19,000)		Varied pine forests, with lichen and moss; lime and oak forests; discontinuous section of taiga on forest steppe
Voronezh (including Khoper reserve) (Voronezh and Lipetsk *oblasti*)	182 (116,000)		Oak and pine forests, with groves of European alder along Usman river, established to increase number of beaver; many roe deer; Khoper includes oak and aspen groves and alder woods along Khoper river, protecting especially muskrat and beaver; bison
Zhigulevsk (Kuibyshev *oblast*)	53 (33,750)		Oak groves; residual pines on limestone; picturesque cliffs and crags
Armenian S.S.R.			
Dilizhan	113 (72,348)	1958	Northern slopes of lesser Caucasian range and basin of Kura river; groves and sparse woods
Garni	103 (65,900)	1958	Basin of Azat and Veda rivers, from 900 to 2,000 m.; scenery with waterfalls; Armenian mouflon, bezoar goat, boar, bear
Azerbaijan S.S.R.			
Gek-Gel	27 (17,500)		Upper forest belt and sub-alpine meadows; Lake Gek-Gel, formed by landslide in A.D. 1139; bear, marten, roe deer
Kyzylagach	363 (232,500)	1929	Gulf of Kirov in the Caspian sea and adjacent islands; coastal reed and salt marshes, wintering habitat of waterfowl, waders, flamingos, bustards and other birds
Turianchay	50 (31,324)		Protects the only habitat of elder pine in the world, a stand of thick-trunked pistache and desert vegetation
Zakataly	109 (62,490)	1930	Southern slope of greater Caucasian range, rising to 3,668 m.; zones of forest and alpine meadows; Dagestan mountain goat, chamois, deer, boar and other wildlife

TABLE VII.—*Principal Parks and Reserves in Europe* (*Continued*)

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
U.S.S.R. (*Cont.*)			
Belorussian S.S.R.			
Berezina	262 (161,500)	1925	Pine groves and spruce woods on Berezina river; to protect habitat of beaver and other wildlife for eventual distribution to other areas
Estonian S.S.R.			
Matsalu	42 (27,170)		Matsalu gulf and basin of Kassari river; nesting grounds and migratory routes of waterfowl and other birds, largest colony of graylag geese in Baltic area
Nigula	11 (6,825)	1957	Pine and sphagnum marsh
Vaika	0.1 (88)	1957	Eider duck and other sea birds
Viydumyaye	2 (1,493)	1957	Rare and endemic plants on Saaremaa Island
Georgian S.S.R.			
Adzhameti	18 5 (11,883)	1957	Residual stands of Imeritian oak, *Quercus hartwissiana*, and *Kolkhidian zelkova*
Babaneuli	3 (1,976)	1960	To preserve stands of *Kolkhidian zelkova*
Batsarsky	12 (7,630)	1957	To preserve residual yew groves and stands of beech
Borzhom	56 (35,875)	1959	Forested western part of Trialeti range; mineral springs
Kintrish	23 (15,000)	1959	Preserves native species of trees
Kolkhida	2 (1,250)	1959	Lake Palnostomi, wintering grounds of waterfowl
Lagodekhi	52 (33,250)	1912	Forested mountains and alpine meadows; mountain goat, deer and other wildlife
Mariamdzhavarsky	4 (2,750)	1959	Scotch pine groves
Ritsa	62 (39,820)	1957	Lake Ritsa and deciduous forests; mountain goat, chamois, roe deer
Saguram	19.5 (12,500)	1957	Residual tertiary vegetation
Satapliysky	1.2 (750)	1957	Limestone caves with fossils
Vashlovani	26 (16,900)	1957	Steppe, semidesert and stands of pistache and juniper; central Asian gazelle
Kazakh S.S.R.			
Alma-Ata	276 (177,000)	1960	Forested mountains of northern Tien Shan, rising to 3,000 m., with meadows and glaciers; bear, Siberian deer, central Asian gazelle, mountain sheep and other wildlife
Aksu-Dzhabaglinsky	273 (185,230)	1926	Talass Alatau range, rising to 4,000 m , Aksu river canyon; snow leopard, bear, mountain sheep, bustard and other wildlife
Barsa-Kelmes	77 (49,500)	1939	Coast of Lake Aral and Barsa-Kelmes Island; onager and central Asian gazelle introduced; gulls, waterfowl and flamingos on shore
Kirgiz S.S.R.			
Issyk-Kul	2,860 (1,830,552)	1958	Preservation and expansion of game animals, birds, fish
Sarychelek	76 (49,129)		Semenov fir, Schrenk spruce forest, with nut and fruit trees, in southern Tien Shan; water conservation
Latvian S.S.R.			
Engures	5 (3,350)		Lake Engures, habitat of nesting and migratory birds
Grini	2.7 (1,750)		Only habitat of cross-leaved heath (*Erica tetralix*) in U.S.S.R.
Moricsala	3 (2,088)	1957	Gulf and islands in Lake Usmas, with deciduous forests and rare herbaceous plants
Šlītere	31 (19,620)		Protects virgin forest
Lithuanian S.S.R.			
Žuvintas	12 (7,918)	1946	Lake Zuvinto and adjacent forest and marsh areas, nesting grounds of waterfowl, including 50 pairs of whooper swans
U.S.S.R. (*Cont.*)			
Tadzhik S.S.R.			
Childukhtaron	59 (37,500)		Residual nut and maple forests
Gazimailik	59 (37,500)		Natural environment of Kok-Tau range
Iskanderkul	117 (75,000)		Deciduous and juniper forest and high mountain steppe; picturesque mountain lake at 2,176 m ; snow leopard, ibex
Ramit	59 (37,500)	1959	Forested upper reaches of Kafirnigan river; alpine meadows
Tigrovaia Balka	162 (103,375)		Southern deserts of central Asia; flood plain forest of Vakhsh river; Tugai deer, central Asian gazelle, bird life
Turkmen S.S.R.			
Badkhyz	294 (212,173)	1941	Hilly plains, spurs of Paropamiz range and deep Yeroilanduz salt depression; 500 onager, also gazelle and cheetah
Gasan-Kuli	272 (174,150)	1932	Reed and salt marshes on Caspian sea; waterfowl wintering grounds; only habitat in central Asia of the partridge *Francolinus orientalis*
Repetek	135 (86,500)		Eastern sand desert of Kara-Kum, with desert plants; gazelle, the wild cat *Felis margarita*, the hare *Lepus tolai*, sand jerboa, reptiles, bird life
Ukrainian S.S.R.			
Azov-Sivash	47 (30,000)		*Solonets* steppe on islands and salt marshes around Sivash; protects migratory and wintering waterfowl; deer and game birds acclimatized on Biryuchy Island, and pheasants and the goat antelope *Saiga tatarica* have been introduced
Aksaniya-Nova	2 (1,250)		Residual virgin steppe
Black Sea	47 (30,000)	1927	Protects migratory and wintering waterfowl and nesting gulls and terns, as well as other bird life
Crimea	118 (75,500)		Highest peak in Crimean mountains, Roman-Kosh (1,545 m.); zones of oak, beech, mountain steppe, pasture, with Crimean and Scotch pine on southern slope; deer, mouflon (acclimatized), stone marten, Crimean barbel and other wildlife
Kamennye Mogily	1.4 (890)	1927	Granitic hills rising to 100 m. above stony steppe, with rare types of plants
Khomutovskaya Steppe	4 (2,564)	1926	Virgin feather grass and meadow steppe, with semidesert and desert animal life
Mikhaylovskaya Steppe	0.8 (505)	1928	Virgin meadow steppe
Streletskaya Steppe	2 (1,313)	1948	Virgin grass steppe; habitat of *Marmota bobac*
Uzbek S.S.R.			
Amu-Darya	234 (150,000)		Delta and marshes of Amu-Darya river, with nesting and migratory waterfowl, flamingo, bustard and other bird life; central Asian gazelle saiga, boar
Chatkal Mountain forest	137 (87,500)	1947	Stands of juniper and deciduous trees in western Tien Shan; central Asian goat, white-toed brown bear, snow leopard, Pallas's cat, other mammals and varied bird life
Zaamin Mountain forest	33 (25,935)	1960	Forested mountains and alpine meadows of northern slope of Turkestan range; bear, lynx, mountain goat, mountain sheep and other wildlife
YUGOSLAVIA			
Fruska Gora National park	89 (57,125)	1960	Hills; native vegetation; birds; archaeological sites
Biogradska Gora National park	8.2 (5,250)	1952	Virgin forest of fir, spruce, beech, maple; red and roe deer, trout, capercaillies
Durmitor National park	125 (80,000)	1952	Five canyons, 14 lakes; mixed forest; ammonite fossils; chamois, roe deer, bears

TABLE VII.—*Principal Parks and Reserves in Europe (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
YUGOSLAVIA (*Cont.*)			
Galičica National park	93 (59,400)	1958	Mixed high-altitude forests
Lovćen National park	8 (5,000)	1952	Mountain massif; fjords; overlooks Adriatic sea
Mavrovo National park	286 (182,720)	1949	Mountainous; bears and lynx; power reservoir
Paklenica National park	15 (9,900)	1949	Two wild scenic canyons; mixed forest; cliffs and rocks
Perister National park	47 (30,000)	1949	Two glacial lakes with abundant trout; pine forest
Plitvička jezera National park	75 (47,900)	1949	Mountain; mixed forest; bears, roe deer, capercaillies; 16 lakes with trout and crayfish; 4 limestone caves
YUGOSLAVIA (*Cont.*)			
Risnjak National park	13 (8,600)	1953	Dinaric mountain system; Balkan and alpine vegetation meets Mediterranean types; mixed forest; rich fauna
Trebević National park	4 (2,471)	1954	Forest, meadows, wildflowers; animal life includes roe deer, bears, capercaillies
Mljetska jezera reserve	12 (7,750)	1948	Island with three salt lakes; Aleppo pine and dense brush
Perućica reserve	6 (3,585)	1952	Virgin forest of beech, maple, ash, hornbeam, fir, spruce, pine; chamois, roe deer, bears, wild boars, martens, golden eagles; waterfall

countries are of much more recent establishment. In Poland, nature protection began in the 15th century, when the aurochs and other endangered species were given royal protection, but it was not until 1919 that a provisional state commission for the protection of nature was founded; this commission initiated establishment of national parks and enactment of conservation legislation. A nature protection act, which placed the national parks under the ministry of forestry, was passed in 1949. Scientific research is conducted in the parks by many institutions, under the direction of the Polish Academy of Sciences.

In the Federal Republic of Germany, legislative control over nature protection was the responsibility of the *Länder* after 1945; the federal government acts to develop uniformity of state legislation. Many agencies are concerned with problems relating to nature protection and a large volume of law has been promulgated, the most fundamental being the Reich Nature Protection law of 1935. In addition, there are numerous private organizations that co-ordinate their efforts and co-operate with the official agencies as closely as possible. Their problems are complicated by the fact that all nature reserves in Germany are leased from private landholders, except a part of the Lüneburg Heath reserve that is owned by the Nature Reserves society. A variance of opinion exists between those people interested in the establishment of nature reserves primarily for the strict protection of species and associations of vegetation and animal life and related scientific research, and those who regard outdoor recreation as an essential purpose of reserves. In practice, reserves serving both purposes have been created, and in addition to the major nature parks there are hundreds of smaller reserves of scientific significance and scenic importance.

In Finland, legislation enacted in 1923, 1938 and 1956 provides for the establishment of reserve areas on government land. National parks are set aside on virgin land for the preservation of animal life and vegetation and for visitor enjoyment. Nature reserves are established mainly for scientific purposes and entry is by permit. Of ten national parks and reserves created in 1938, six were located on the area ceded to the Soviet Union; to compensate for their loss the 1956 law was passed to establish additional parks and reserves in southern Finland. The national parks and nature reserves protect forested mountains, lakes, coastal shore lines and islands. Roads, trails, lodges and campgrounds and other accommodations are provided in the national parks.

National parks and nature reserves in the U.S.S.R. are state property and come under the national budget. Special organizations or committees set up by the council of ministers direct the work in the parks, the responsibility in some cases resting with the U.S.S.R. Academy of Sciences or the academies of sciences of the union republics.

The natural features as a whole are under protection and may be put to use only by permission of the government of the U.S.S.R. or of the union republics. If any special features in a certain area are protected, the area is declared a prohibited area; other-

TABLE VIII.—*Principal Parks and Reserves in Australasia*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
AUSTRALIA			
New South Wales			
Blue Mountains National park	359 (230,000)	1959	Rugged scenic sandstone country in Blue mountains, with peaks, towering cliffs, deep gorges and bushland valleys; stunted trees on higher slopes, dense rain forest in valleys; with eucalypts and blue gums; varied wildlife
Brisbane Water National park	25 (16,000)	1959	Broad ridges dropping to tidal waters; rain forest in gullies; Hawkesbury sandstones have unique vegetation and abundant wildflowers; Bouddi National park (1,280 ac.) and sanctuaries adjacent
New England National park	72 (46,000)	1935	East slopes of Great Dividing range, to 5,280 ft., largely rain forest, with hardwoods on ridge tops; varied wildlife
Royal National park	56 (36,000)	1955	Forest reserve, with coastal surf beaches
Warrumbungle National park	22 (14,000)	1953	Rugged volcanic Warrumbungle range; kangaroos, wallaroos, giant wedge-tail eagles, etc.
Kosciusko State park	2,344 (1,500,000)	1944	Mt. Kosciusko, 7,316 ft., and other peaks and rolling grassy plateaus; Yarrangubilly caves; Snowy mountains hydroelectric scheme is mainly within park; winter sports area
AUSTRALIA (*Cont.*)			
New South Wales (Cont.)			
Kuring-gai Chase	59 (38,000)	1894	Exposed sandstone ridges, bushland scrub, rain forest in gullies, tidal inlets; profuse native flowers; koalas, kangaroos, dormouse "opossums" (phalangers), Albert lyrebird, etc.
Morton National park	70 (45,000)	1938	Mountain terrain with sandstone summits and deep gorges; open bloodwood-scribbly gum forest and heathland on higher slopes, hardwood forests and rain forest in gorges
Nadgee Faunal reserve	44 (28,000)	1957	Combination of seashore, lagoon, moorland, swamp, river valley, open forest and mountain habitat, with great variety of plant and animal life
Northern Territory			
Ayers Rock–Mount Olga	487 (311,700)	1958	Ayers Rock, 20 mi from Mt. Olga (3,507 ft.), is a huge monolith 2,850 ft. rising 1,143 ft. above the surrounding plain; numerous native paintings on rocks; desert oak, mulga, mallee, bloodwood and spinifex; kangaroo, wallaby, bandicoot, euro, many lizards, varied bird life

TABLE VIII.—*Principal Parks and Reserves in Australasia (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
AUSTRALIA (*Cont.*) *Northern Territory (Cont.)*			
Katherine Gorge	88 (56,069)	1963	Walls of red and brown quartzite tower 200 ft. on each side; variety of shrubs, trees and palms grow from ledges and crevices; fish and fresh-water crocodiles; parrots and many types of finches; wallabies in the hills
Queensland			
Bellenden-Ker National park	125 (80,140)	1921	Mt. Bartle Frère (5,275 ft.) and other jungle-clad peaks in McPherson and Great Dividing ranges; kangaroos
Carnarvon Gorge	104 (66,480)		"The Grand Canyon of Queensland"; a vast chasm, 20 mi. long, 50–400 yd. wide with vertical sandstone cliffs up to 600 ft. high; many caves containing aboriginal art; open forest; platypus
Eungella National park	192 (122,600)	1941	Dense jungle and tropical forest; waterfalls on peaks up to 4,000 ft.
Lamington National park	76 (48,510)	1915	Magnificent mountain scenery, waterfalls and forests which include the antarctic beech; Albert lyrebird, rufous scrub-bird, marsupials
Hinchinbrook Island National park	152 (97,232)		Picturesque mountain and waterfall scenery with numerous caves
South Australia			
Belair	3.2 (2,064)		Public recreation area; mainly hilly bushland; eucalyptus; kangaroo, wallaby, emu, koala
Flinders Chase	212 (135,700)	1905; 1919	Ancient peneplain and coastal cliffs and beaches on Kangaroo Island; great gray and sooty kangaroos, endemic black-faced kangaroo, wallaby, echidna, phalangers; koala and platypus introduced; penguins, pelicans and other birds; orchids
Para Wirra	4.1 (2,596)	1963	Rocky gorges; dam and artificial lake; kangaroos
Tasmania			
Cradle Mountain-Lake St Clair National park	529 (338,560)	1921	Mountain region, 2,000 ft to 5,305 ft. (Mt. Ossa), with rivers and lakes; forests of King William pine, pencil pine, eucalypt, Tasmanian rain forest, savanna and plains; marsupials and other wildlife
Mt. Field National park	63 (40,034)	1916	Glaciated valleys with forests of giant eucalypt and rain forest, rising to Mt Field West (4,721 ft.) and highland moors; Russell Falls, areas of vegetation unique to Tasmania: mountain shrimp in mountain tarns; wildlife plentiful
Victoria			
Kinglake National park	22 (14,079)	1928	Heavily forested south slopes of Plenty ranges, with deep fern gullies and waterfalls; 326 plant species recorded, including rare orchids; several species of kangaroo, wallaby, bandicoot, dasyure, wombat, koala, echidna, platypus, reptiles and a variety of birds
Mallacoota Inlet National park	17.5 (11,225)	1932	Evergreen bush on Genoa river, wildlife
Mt. Buffalo National park	43 (27,280)	1898	Granite plateau rising to 5,645 ft.; wet sclerophyll forest, subalpine woodland, sod tussock grassland in valleys; wombat, wallaby, echidna, kangaroo, lyrebird and other bird life
Wilson's Promontory National park	160 (102,379)	1905	Magnificent mountain and coastal scenery; fern gullies; wombat, koala, emu and other wildlife
Wyperfeld National park (Mallee)	218 (139,760)	1921	Semidesert Mallee region in west, sand hills lightly covered with heath and dwarf shrubs in east; black box and red gum trees on creek flats; black-faced kangaroo; Regent parrot, cockatoo, emu, mallee fowl

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
AUSTRALIA (*Cont.*) *Western Australia*			
Kalbarri National park	560 (358,000)	1963	Rocky gorges; rich in native flora
Nornalup National park	52 (33,139)	1957	Heavily timbered with karri, marri and jarrah trees; bottlebrush plants; ocean beaches
Penguin Island reserve	0.05 (31)	1957	Sanctuary for penguins
Porongorups National park	9 (5,651)	1957	Rugged hills in Porongorup range; stands of karri trees in valleys
Yanchep National park	10 (6,422)	1957	Caves; koalas, kangaroos, emus, black swans
BRITISH SOLOMON ISLANDS PROTECTORATE			
Queen Elizabeth park	24 (15,200)	1954	Contains Mt. Austen and the Mantanikai river valley, a very broken country interlaced with ridges and valleys; tropical hardwood forests; bird life
FIJI			
Ravilevu Nature reserve	15.5 (9,930)	1959	Forested mountain area with spectacular waterfalls and gorges; rare birds
Tomaniivi Nature reserve	6 (3,720)	1958	Mt. Victoria (4,341 ft.) and surrounding forests; rare birds; orchids
NEW ZEALAND *National Parks*			
Abel Tasman (South Island)	70 (44,635)	1942	Coastal and elevated region along Tasman bay, with mixed forests and beaches
Arthur's Pass (South Island)	384 (242,888)	1929	Southern Alps, with glaciers, river valleys and virgin forests; birds; 29,990 ac. wilderness area where buildings, horses and vehicles are excluded
Egmont (North Island)	129 (82,290)	1900	Mt. Egmont, with alpine vegetation, subtropical forests, sphagnum swamp and waterfalls; kiwi, rifleman bird, fantail and other birds
Fiordland (South Island)	4,724 (3,023,102)	1952	Mountain forests and fjords on coastline, with lakes, rivers and waterfalls; only habitat of the rare flightless rail or takahe (*Notornis hochstetteri*) and of the large owl parrot or kakapo (*Strigops habroptilus*); other birds; seals
Mt. Aspiring (South Island)	769 (492,300)	1964	Relatively remote mountainous area dominated by Mt. Aspiring (9,957 ft.); beech and rain forest
Mount Cook (South Island)	270 (172,979)	1953	15 peaks above 10,000 ft. in Southern Alps, Tasman glacier and other glaciers, montane scrub and alpine growth
Nelson Lakes (South Island)	221 (141,127)	1956	Two lakes located in mountainous terrain, with mainly beech forest
Tongariro (North Island)	260 (166,519)	1894	Three volcanoes, forests, treeless plains, and Mt Ruapehu with small glaciers; crater lake; hot springs and geysers
Urewera (North Island)	770 (493,011)	1954	Mountain ranges, crags, waterfalls and virgin forests; Maori-owned Lake Waikareiti; kiwi and other bird life
Westland (South Island)	329 (210,257)	1960	Western slope of Alpine chain (over 11,000 ft.) extending to sea level; glaciers, lakes, dense forests
Scenic, Natural and Historic Reserves			
Waipoua Forest reserve	36 (22,800)	1952	Kauri pine (*Agathis australis*)
Kapiti Island Bird sanctuary	6 (4,300)		Bush birds, waterfowl, sea birds, tuatara
Little Barrier Island Bird sanctuary	11 (6,960)	1894	Bush birds
Cape Kidnapper Gannet sanctuary (North Island)	0.05 (32)	1914	Only known mainland gannet colony
Waitangiroto White Heron colony (South Island)	3 (1,910)	1929	Only known nesting place of the white heron

TABLE IX.—*Principal Parks and Reserves in Central and South America*

Name and location	Total gross area in sq mi (approx. acreage in parens)	Date established	Principal features
ARGENTINA			
El Rey	140 (89,600)	1948	Subtropical forests on border of Bolivia, with tapir, jaguar, giant anteater, birds, reptiles and other wildlife
Iguaçu	210 (134,400)	1934	Subtropical forest on Brazilian border, with cataracts, including Iguaçu falls, 240 ft. high; abundant wildlife
Laguna Blanca	44 (28,200)	1949	Black-necked swans
Lanín	1,520 (972,800)	1937	Lanín volcano on Chilean border, with *Araucaria* forests and many lakes; varied wildlife
Los Alerces	1,000 (640,000)	1937	Mountainous region with immense forests; ancient glaciers, lakes; principal habitat of guemal deer; other wildlife
Los Glaciares	2,300 (1,472,000)	1937	Southern Andes on border of Chile, with glaciers, lakes and unusual plant associations, guanaco, chinchilla, guemal and pudu deer, condor and other wildlife
Nahuel Huapi	3,057 (1,956,500)	1922; 1934	Andean peaks on Chilean border, with glaciers, forests and lakes; guemal and pudu deer, condor and other wildlife
Perito Francisco P. Moreno	450 (288,000)	1936	Forested Andean peaks on southern border of Chile; habitat of guanaco, guemal deer, Patagonian fox, condor, swan and other wildlife
Angel Gallardo Nature reserve	231 (147,800)	1945	Subtropical forests and swamps of the Chaco, with pure forests of quebracho (*Schinopsis balansae*) and characteristic animal life
Tierra del Fuego	251 (160,620)	1961	Spectacular lakes and mountains
BAHAMA ISLANDS			
Exuma Cays National Land and Sea park	176 (112,640)	1959	Hundreds of tropical islets, coral reefs, sea gardens; marine and bird life, tropical vegetation, thousands of green turtles; unique geological phenomena, white sand beaches and dunes
Flamingo Colony reserve	287 (183,680)	1959	West Indian flamingos, total flock of 17,000, one of the largest of the few remaining colonies in the world
BERMUDA			
Castle Harbour Islands reserve	0.05 (30)	1961	Last breeding ground for Bermuda petrel and other sea birds; rugged offshore islets
Paget Marsh reserve	0.04 (25)	1950–66	Island valley containing virgin marsh flora and palmetto forest characteristic of prehistoric Bermuda
Spittal Pond National park	0.09 (60)	1954–61	Coastal valley; waterfowl refuge
Warwick and Southampton Beaches National park	0.15 (100)		Beaches, coves, bays, rock cliffs, sand dunes
BOLIVIA			
Cerro Miriqui y Saja National park	(*)	1945	Some of the highest forests in the world; chinchillas, vicunas
Tuni Condori National park	(*)	1942	Mountainous; panorama of snow fields; condors, deer, fox, hares and other fauna
Cerro de Tapilla reserve	(*)	1940	Chinchillas
Bella Vista National park	(*)	1964	Subtropical forests; variety of forest species and native orchids
Cerro de Comanche National park	(*)	1963	Extraordinary amounts of flowers; these flowers bloom every 125 years but there are always some in bloom
Tunari National park	(*)	1962	Native and exotic species of flora
BRAZIL			
Iguaçu National park	792 (506,566)	1939	Mountains and canyons, on Argentine border, with virgin evergreen forests and tropical vegetation; abundant wildlife
Itatiaia National park	46 (29,512)	1937	Mountain range reaching 7,546 ft. (2,300 m.); numerous lakes and rivers, unique geological formations; rich in plant life; abundant wildlife, birds and insects
BRAZIL (*Cont.*)			
Serra dos Orgãos National park	39 (24,711)	1939	Mountainous area extending from sea level to 8,202 ft. (2,500 m.); dense forest inhabited by large animal population; orchids and many other varieties of flowers and plants of peculiar beauty; many rivers
BRITISH HONDURAS			
Chiquibul reserve	714 (456,960)	1956	Tropical hardwood forest; tapirs, deer, wild pigs, jaguars, pumas, crocodiles
Columbia reserve	173 (110,720)	1954	Forest; tapirs, deer, wild pigs, jaguars, pumas, crocodiles
Manatee reserve	177 (113,280)	1959	Forest; tapirs, deer, crocodiles, pumas
Mountain Pine Ridge reserve	214 (136,960)	1959	Pine forest, savannas, palmettos; tapirs, deer, wild pigs, jaguars, pumas
Sibun reserve	169 (110,060)	1959	Tropical hardwood forest; tapirs, pumas, crocodiles
CHILE			
Cabo de Hornos	244 (155,908)	1945	Protects islands, some in primeval state, in Strait of Magellan; aquatic animals
Easter Island and Juan Fernández	66 (42,007)	1935	Protect vegetation, animal life and archaeological relics on islands in Pacific ocean
Fray Jorge	20 (12,847)	1941	Extensive forests and wildlife
Los Paraguas	70 (44,479)	1940	Spectacular scenery, including the Llaima volcano; *Araucaria* forests
Nahuelbuta	21 (13,381)	1939	Coastal cordilleras, primeval *Araucaria* and other forest species
Puyehue National park	290 (185,329)	1941	Many small lakes; thermal waters; volcanic activity
San Rafael National park	2,278 (1,457,922)	1945	Almost extinct varieties of trees and animals; glaciers
COLOMBIA			
Farallones de Cali National park	463 (296,400)	1962	Features information unavailable
Sierra de la Macarena National park	4,366 (2,794,311)	1948	Features information unavailable
Tairona National park	442 (282,939)	1964	Features information unavailable
Volcán de Puracé National park	46 (29,640)	1961	Features information unavailable
COSTA RICA			
Cabo Blanco reserve	5 (3,200)	1963	Forest fauna
Rio Macho reserve	424 (271,360)	1964	Watershed forest
EL SALVADOR			
Atecozol National park	0.1 (69)	1953	Fish ponds; forest; flowers
Cerro de las Pavas National park	0.03 (24.8)	1949	Mountains; valley of Virgin of Fatima; forest; gardens
Los Chorros National park	0.04 (27)	1958	Natural woods, waterfalls, ponds
GUATEMALA			
Atitlán National park and reserve	67 (42,880)	1955	Lake Atitlán is bordered by active volcanoes and the park supports pine, cypress and oak forests on their slopes; deer, squirrel and bird life, including a grebe endemic to the lake
Río Dulce National park	117 (74,880)	1955	Lake Izabal and Río Dulce from Atlantic ocean to ruins of San Felipe castle; magnificent jungle scenery, with tapir, jaguar, howler monkey and tropic bird life; open savannas with mahogany, blood trees and other native trees
Santa Rosalía reserve	1.9 (1,280)	1955	Pine and deciduous forests, with abundant wildlife, including deer, the raccoon mapache (*Procyon lotor*)
Tikal National park	224 (143,360)	1955	Tropical forest in El Petén, with mahogany, Spanish cedar and the sapodilla tree, or *chicosapote* (*Achras sapota*); deer, puma, jaguar, ocelot, tapir, mapache and other wildlife; Mayan ruins

*Area figures not available.

TABLE IX.—*Principal Parks and Reserves in Central and South America (Continued)*

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
GUATEMALA (*Cont.*)			
Cerro del Baul National park	4.6 (2,944)	1955	Mountains; pine and cypress forests; wildlife
Cerro Miramundo National park	3.5 (2,223)	1966	Xerophytic forest; mountain goats; panoramic views
El Pino reserve	1.3 (864)	1955	Pine and cypress forests; coyotes
Laguna el Pino National park	2.3 (1,472)	1955	Irregular topography; lagoons
Los Aposentos National park	0.8 (494)	1955	Pine forests, evergreens; recreation area; wildlife
United Nations National Forest park	1.9 (1,235)	1955	Plains of Pacific coast; lake; forests; wildlife
GUYANA			
Kaieteur	45 (28,800)	1930	Savanna and brushwood fauna on Potaro river; Kaieteur falls; tropical birds
MEXICO			
Cañon del Río Blanco (Veracruz)	210 (134,102)	1938	Forested headwaters of Río Blanco
Cumbres de Monterrey (Nuevo León)	952 (609,100)	1939	In Sierra Madre Oriental range; thick pine forests and wildlife
El Tepozteco (Morelos)	93 (59,304)	1937	Protects archaeological and natural features
Grutas de Cacahuamilpa (Guerrero)	5 (3,044)	1936	Spectacular cave formations; source of Amacuzac river
Ixtacihuatl-Popocatépetl (Puebla, Morelos, Mexico)	99 (63,452)	1935	Two volcanoes rising to over 5,000 m (17,000 ft.); with perpetual snows
La Malinche (Tlaxcala)	152 (97,421)	1938	La Malinche peak and forested slopes
Lagunas de Chacahua (Oaxaca)	55 (35,056)	1937	Lagoons bordering centre of Mixtec kingdom at time of Spanish conquest, waterfalls
Lagunas de Montebello National park	22 (14,453)	1959	Fifty-nine lakes of different colours surrounded by forests of pine and oak, semitropical and tropical plants; many varieties of orchids
Nevado de Toluca (Mexico)	259 (165,557)	1936	Nevado de Toluca (4,623 m. [15,167 ft.]) with lagoons in extinct crater; pine and oyamel forests; wildlife
Pico de Orizaba (Puebla and Veracruz)	76 (48,802)	1936	Citlaltepetl (5,700 m. [18,701 ft.]), highest peak in Mexico; forests include giant trees
Pico de Tancítaro (Michoacán)	113 (72,440)	1940	Extinct volcano
Sierra de San Pedro Mártir (Baja Calif.)	243 (155,673)	1947	San Pedro mountain range, with canyons, forests, and wildlife
Volcan de Colima (Colima Jalisco)	86 (54,856)	1936	Active volcano with subtropical forest on lower slopes, and pine and evergreen oaks above

Name and location	Total gross area in sq.mi. (approx. acreage in parens.)	Date established	Principal features
PANAMA			
Forestal de la Yeguada reserve	19 (12,355)	1960	Lake, volcanic depressions; unique ecological and geological features
Forestal de Tonosi reserve	74 (47,234)	1960	Mountains; subtropical and tropical animals; flowering trees
Forestal de Chepigana reserve	1,014 (648,994)	1960	Only bold coast line in Panama; mountain range; varied and abundant flora and fauna
Nacional reserve	369 (236,129)	1963	Mountains; valuable timber species; game animals
"Altos de Campana"	10.2 (6,500)	1966	Biological elements of four life zones; Pacific and Caribbean slopes overlook rich scenery
SURINAM			
Brinckheuvel National park	23 (14,820)	1961	Deer, armadillos, wild boars, tapirs, jaguars, pumas
Coppenamemonding National park	39 (24,700)	1966	Breeding grounds for red ibis and brown pelicans
Kaysergebergte National park	618 (395,200)	1966	Tropical jungle
Tafelberg National park	154 (98,800)	1966	Sandstone formations; mountain fauna and flora
Voltzberg National park	216 (138,320)	1961	Deer, armadillos, wild boars, tapirs, jaguars, pumas
Wia Wia National park	139 (88,920)	1961	Breeding area for turtles
URUGUAY			
San Miguel National park	6 (3,740)		Scenic coastal area
Santa Teresa	13 (8,220)		Scenic coastal area
VENEZUELA			
Avila	312.5 (200,000)	1958	Forested mountain area between Caracas and the Caribbean sea
Guatopo	352 (225,000)	1958	Established to safeguard watershed endangered by agricultural burning; natural cloud forest on Cerro Azul in eastern section
Rancho Grande (Henry Pittier)	352 (225,000)	1937	Primeval tropical cloud forest in Cordillera de la Costa, with abundant wildlife, especially tropical birds; biological research station
Sierra Nevada de Mérida	625 (400,000)	1952	Pico Bolívar (16,411 ft.) and other snow-clad peaks in Venezuelan Andes near Colombia, forested on lower slopes, with glacial lakes
Alexander von Humboldt Natural monument		1949	Guácharo caves, with limestone formations and oilbirds (*Staetornis caripensis*)
Yacambú		1962	Scenic forested volcano

wise the parks are open to visitors insofar as the maintenance of the parks allows. Hunting and fishing or other destruction of wildlife and plants, as well as mining and livestock grazing, are prohibited.

Extensive scientific research is carried out by personnel attached to the park administrations, by other scientific bodies and by universities. The results are published by the national parks themselves, some of which publish their own journals, and in scientific periodicals. Every park has a natural history museum, and the most popular parks, such as the Crimea, Caucasus, Ritza and Teberda, have prepared special itineraries for tourists. Several films have been made on the national parks. The U.S.S.R. also has set aside nature reserves for the protection of particular features and resources.

VII. AUSTRALASIA

The preservation of natural areas and wildlife in Australia is, generally speaking, on a state rather than a commonwealth basis. In New South Wales, for example, each national park is administered by a separate trust of local residents or, in some cases, by representatives of government departments. Western Australia has a similar system. The forestry department administers the national parks of Queensland, supported in an advisory capacity by citizens' organizations, notably the National Parks association of Queensland. An official National Parks authority has been established in Victoria, also assisted by a National Parks association. A board of commissioners in South Australia and a Scenery Preservation board in Tasmania have jurisdiction over national parks and reserves in those states.

Within the parks and reserves are representative examples of most of the scenic characteristics of the continent—mountain ranges, gorges, waterfalls, marshes and lagoons—and its extraordinary vegetation and animal life. They are vital to the perpetuation of endemic species of wildlife, including unique marsupials, platypuses and other rare animals, and most unusual bird life. Some of these are dependent upon preservation of particular habitat or plant associations, an example being the koala, which requires oils of certain varieties of eucalyptus trees in its diet. Some Australian reserves are in remote sections, others are popular for camping, hiking, swimming and other outdoor pursuits. The more accessible parks have excellent accommodations.

In New Zealand, public reserves in general, including those set apart for the preservation of vegetation and animal life, are administered by the department of lands and survey of the National Parks authority. The national park board of each park is charged with the protection and control of wildlife, and the regulation of shooting of such wildlife as is considered game. Research and field work are conducted by the wildlife division of the department of internal affairs, the department of scientific and industrial research and various museums. In New Zealand

native wildlife consists mainly of birds, there being no indigenous land mammals other than rare bats and the native rat. Marine animals are protected by the marine department. The deficiency of wild game animals led to the introduction of various species for sporting purposes in the latter half of the 19th and the beginning of the 20th century. These included red deer, wapiti, chamois, Himalayan tahr and opossum. Pigs and goats were allowed to run wild, and introduced rabbits soon became so great a pest that stoats, weasels and ferrets were let loose to prey upon them. A spectacular result of their importation was the rapid diminution in the numbers of ground-dwelling and flightless birds and significant effects on other birds. Active extermination measures had to be taken against many of the foreign animals in order to try to restore the balance.

The Wildlife act, 1953, provided for the establishment of wildlife sanctuaries and refuges; it also protected most indigenous species wherever they might be found. Most reserves protect native plants as well as animals and some are set aside for the preservation of a certain species of plant; *e.g.*, the stands of kauri pine at Waipoua, the very rare evergreen shrub *Pittosporum obcordatum* in Hurumua reserve and the buttercup *Ranunculus paucifolium* near Mount White sheep station. There are also a large number of scenic reserves. The main purpose of the national parks is to provide untouched country for the enjoyment of the people, but their work in the preservation of the indigenous birds is also vitally important. In the parks of the North Island may be seen tuis, bellbirds, rifleman birds, owlet-frogmouths (moreporks), wekas and many others. But the largest of the parks, Fiordland, in the South Island, contains the greatest number of birds peculiar to New Zealand, especially the famous flightless rail or takahe (*Notornis hochstetteri*), long thought extinct but rediscovered in 1948. The area in which the takahe occurs is specially protected and no one may enter without a permit.

VIII. CENTRAL AND SOUTH AMERICA

Mexico first reserved land to protect historical sites late in the 19th century, but the establishment of national parks for the preservation of natural features and vegetation and animal life was undertaken on a major scale in the 1930s. Included in the system are spectacular scenic areas. The parks also protect vital watersheds, forests and wildlife in a country which has suffered devastating destruction of its natural resources from shortsighted exploitation. The most famous landmark in Mexico is the towering snow-clad summits of Ixtacihuatl-Popocatépetl, visible from the capital city and visited by thousands of people annually. Other peaks in the Sierra Madre ranges, caverns, forests and lagoons inhabited by myriad waterfowl are protected in other parks.

In Guatemala, national parks have been established to protect outstanding natural and archaeological features. Lake Atitlán, dominated by active volcanoes, resembles scenery found in Java; the precise boundaries of the national park have not been defined. The boat trip up the Río Dulce from Livingston through Lake Izabal, winding amid virgin jungles resounding with the calls of tropical birds and howler monkeys, is a famous attraction. The great plain of El Petén is a region of grasslands and tropical forests, the habitat of abundant wildlife, with buried Mayan cities.

The long-continued destruction of Venezuelan natural resources by overgrazing, fire and abusive agricultural practices stimulated an active conservation program in that country, which has included the establishment of national parks and natural monuments. Avila National park, near Caracas, is a popular recreational area as well as one of scientific importance. The tropical cloud forests in Rancho Grande and Guatopo National parks preserve humid jungle growth on the upper slopes of mountain ranges, with many unusual birds, mammals, reptiles and insects. The Sierra Nevada de Mérida National park is an Andean terrain of exceptional beauty.

The southern Andes possess some of the most spectacular mountain scenery in the world, and several outstanding examples along the Argentine–Chilean border have been set aside as national parks. There live two varieties of Andean deer, the guemal and the pudu, and also guanaco, chinchilla, condor and other unusual animals. Of Argentina's other national parks, El Rey and Iguaçu protect subtropical forests on the Bolivian and Brazilian border, while the Angel Gallardo Nature reserve in the Chaco on the boundary of Paraguay includes dense subtropical forests and swamps. These forests, rich in a variety of unusual plant life, are the habitat of most species of jungle fauna, including tapirs, carnivores and other mammals, many reptiles and myriad species of tropical birds. Often considered to be of almost limitless extent, these forests could easily be destroyed by exploitation.

Several of Chile's national parks are corollaries of the Andean parks in Argentina, protecting similar mountainous terrain and its forests and wildlife. Among Chile's other parks, the Cabo de Hornos National park is difficult of access, a region of gales and cold fogs, established to safeguard islands inhabited by seals and other aquatic mammals and birds. Easter Island is famous for its mysterious archaeological sculptures. Juan Fernández National park supports an endemic vegetation and animal life of scientific importance, which is seriously endangered by livestock grazing.

NATIONAL RESEARCH COUNCIL: *see* NATIONAL ACADEMY OF SCIENCES–NATIONAL RESEARCH COUNCIL.

NATIONAL SAVINGS: *see* SAVING, NATIONAL.

NATIONAL SECURITY COUNCIL, U.S., a council that advises the president of the United States on national security matters that require the co-ordination of domestic, foreign and military policies. Its members are the president, vice-president, secretary of state, secretary of defense and the director of the office of emergency planning.

The need for a national policy co-ordinating group more formal in character than the presidential cabinet was not recognized in the United States until the eve of World War II. It was not until 1938 that a standing liaison committee consisting of the undersecretary of state, the chief of naval operations and the army chief of staff was created. With the onset of World War II, however, policy co-ordination virtually ceased except as it was provided personally by the president, Franklin D. Roosevelt. Not until the last year of the war did a group, the state-war-navy co-ordinating committee (SWNCC), come into being with the express purpose of co-ordinating policy. The SWNCC was ineffective, for it could consider only matters referred to it by one of the departments. It was made up of assistant secretaries and lacked sufficient political prestige to influence policy.

Following World War II, congressional investigation focused attention on the lack of co-ordination that had been a factor in the Pearl Harbor disaster, and there was a general pressure for reorganization of defense agencies. The suggestion for a national security council (NSC) originated in studies by a staff of experts appointed by James V. Forrestal, then secretary of the navy. The NSC was established by law in 1947, and consisted of the president, the secretary of state, the secretary of defense, the secretaries of the three military services and the chairman of the national security resources board (NSRB). When Reorganization Plan 3 abolished the national security resources board, an executive order of March 13, 1953, named the director of the Office of Defense Mobilization to replace the chairman of the NSRB on the council. One of the most important features of the 1947 law was that the NSC was provided with a staff of its own. In time it was felt by those called upon to observe NSC operations that the staff base should be further strengthened and its military topheaviness reduced. These criticisms were taken into account in the National Security act amendments of 1949.

The functioning of the NSC continued to be the object of criticism even after the 1949 reorganization. After Pres. Dwight D. Eisenhower took office in 1953 the NSC was given a new importance and its staff was strengthened by the formation of a planning board. The members of this board, each with the rank of assistant secretary, functioned as representatives of members of the NSC. An Operations Coordinating board was also established.

With the accession of John F. Kennedy as president in 1961 the old structure disappeared. The NSC was, at first, scarcely used at all. It did not meet until after the abortive Cuban invasion of April 1961, but thereafter it began to meet at irregular

intervals. Both the Operations Coordinating board and the planning board were disbanded at the very beginning of the new administration. In their place a planning group began meeting regularly once a week. Representatives from the treasury, state and defense departments attended regularly. No formal agenda was developed, however, and no formal minutes were kept. Major segments of national policy were formed outside the NSC, and the extent to which its advice was followed depended on the policies of the president.

During the administration of Pres. Lyndon B. Johnson the NSC met with some regularity. More frequently, however, President Johnson met with only a few members of the NSC rather than with the council as a whole. (E. L. KH.)

NATIONAL SOCIALISM, the name of a movement known as the Nationalsozialistische Deutsche Arbeiterpartei (N.S.D.A.P.), National Socialist German Workers'—called Nazi—party, led, from 1920, by Adolf Hitler (*q.v.*) in Germany. Its name revealed its emphasis upon nationalism, socialism, Germanism and the working class. Like Benito Mussolini's Fascism, it combined an appeal to extreme and exclusive nationalism and chauvinist expansionism with a revolutionary call to the masses. It had from the beginning many traits in common with Fascism, and National Socialism may be regarded as the German form of Fascism. Both proclaimed themselves the implacable enemies of liberalism and democracy, of individual rights and all movements of international co-operation and peace; both stressed the subordination of the individual to the state, the inequality of men and races, the right of the strong to rule the weak and the necessity of the principle of blind and unswerving obedience to leaders appointed from above. Both praised the military virtues, despised and rejected pacifism, humanitarianism and charity, glorified hatred and conquest and aimed at the transformation of the whole nation into an armed camp perpetually ready for war.

Origins.—National Socialism, however, had its peculiarly German roots. Some can be traced to the Prussian tradition as it developed under the inspiration of great soldier kings, such as Frederick William I and Frederick II, and men of blood and iron, such as Bismarck. This tradition had always regarded the militant spirit and the discipline of the Prussian army as the model for all individual and civic life. To it was added the tradition of political romanticism, with its sharp hostility to rationalism, to the principles underlying the French Revolution and to the "superficiality" of the west, and with its emphasis on instinct, on the past, even on the remote past, and its proclamation of the rights of the exceptional over all universal law and rules. Thus, the exceptional becomes a law unto himself. These two traditions were later enforced by the 19th-century adoration of science and of the laws of nature, which, with their "iron logic," worked out beyond all concepts of good and evil. Further reinforcements came from a biological theory of life that led to the acceptance of that racialism first proclaimed by Joseph Arthur, count de Gobineau, in his *Essai sur l'inégalité des races humaines* (1853–55). It was then propounded by Richard Wagner (1813–83), who combined it with a heroic ideal of the Nordic superman, and by his son-in-law Houston Stewart Chamberlain, whose *Grundlagen des neunzehnten Jahrhunderts* (1899; Eng. trans., *Foundations of the Nineteenth Century*, 1911) profoundly influenced early Hitlerism. To romanticism, National Socialism owed the vague and fluid conceptions of folk as the basis of cultural and political organization, and of *Weltanschauung* or "total world outlook" as opposed in the name of *Kultur* to the more rational civilization of the west.

In addition to these currents in the German tradition, it ought to be pointed out that Hitler's formation was influenced during his youth by specific Austrian movements. National Socialism owed much to Karl Lueger (1844–1910), who organized the Catholic lower middle classes of Vienna in an anticapitalistic and anti-Semitic movement called the Christian Socialist party, but who remained loyal to Habsburg conservatism; and to Georg von Schönerer (1842–1921), who combined racial anti-Semitism with a violent anti-Catholicism and pan-Germanic expansionism and a bitter hostility to the Habsburgs. Schönerer's disciple Karl Hermann Wolf founded among the Sudeten Germans in Bohemia a German Workers' party that later was to assume the name of Deutsche National-Sozialistische Arbeiterpartei. This occurred a few years before Hitler founded his almost identically named N.S.D.A.P. in Munich.

Much in Hitler's ferocious nationalism and his contempt of the Slavs can be explained by the experience of his youth amid the bitter nationality struggles of the multiracial Habsburg empire.

When Hitler started his agitation in Munich immediately after World War I he found the intellectual soil well prepared by the writings of the German romanticists and of the German publicists of the War of Liberation, such as Ernst Moritz Arndt (1769–1860) and Friedrich Ludwig Jahn (1778–1852).

The last years before World War I were characterized by a renewed interest in romanticism and in the War of Liberation of 1813. In those years a German youth movement with its longing for a true community, a *Gemeinschaft*, the rebirth of the nation, and with its vague mystical enthusiasm for leadership and comradeship, expressed the opposition to rationalism and "bourgeois" liberalism. It had come largely under the influence of Friedrich Nietzsche (1844–1900) and the German poet Stefan George (1868–1933). Oswald Spengler (1880–1936; *q.v.*) and Arthur Moeller van den Bruck (1876–1925) can be regarded as the immediate forerunners of National Socialism in the intellectual field.

But the intellectual preparation would in no way have been sufficient for the growth of National Socialism in Germany if the defeat in World War I, with its ensuing disillusionment and pauperization, especially in the lower middle classes, had not paved the way for Hitler's propaganda. The peace treaty of Versailles gave Hitler a starting point, but the violent opposition which he evoked was not directed in reality against the peace treaty but against the fact that Germany had been defeated and that its plans had been frustrated. From the beginning Hitler's propaganda appealed to the military circles, which regarded the peace only as a temporary setback in Germany's expansionist program. Hitler added to the pan-Germanic aspirations for world hegemony the almost mystical fanaticism of a faith in the mission of the German race and the fervour of a social revolutionary gospel.

Psychological Methods and Theoretical Aims.—Though Hitler accepted many elements of the technique of the Bolshevik Revolution, he found a powerful ally in the widespread fear of Bolshevism, which he exploited, first in Germany and then on a worldwide scale, posing as the bulwark against Bolshevism. Thus, he secured the financial and moral support of many conservative elements that misunderstood the revolutionary and nihilistic character of his movement and its many points of similarity (as in its antiliberalism) with Bolshevism. On the other hand, he gained the adherence of the masses by vague promises of an anticapitalistic order. The banner of the N.S.D.A.P. was the red flag of the revolution, but altered to the German imperial colours by the addition of a white circle and a black swastika in the centre. The extraordinary flexibility of Hitler's dynamic doctrine enabled him to stress different elements at different times and to adapt his attitude momentarily to changing circumstances.

Hitler's most important individual contribution to the theory and practice of National Socialism was his deep understanding of mass psychology and mass propaganda in the contemporary world and his perfection of the methods learned from Bolshevik technique. His chapter on propaganda in *Mein Kampf* (1925–27) can be regarded as of the most fundamental importance. He stressed the fact that all propaganda must hold its intellectual level at the capacity of the least intelligent of those at whom it is directed, and that its content of truth does not count compared with the only valid criterion, that of success.

Hitler understood that, especially with as wide and far-reaching a goal as world domination, it was of the utmost importance to be able to present under one common denominator all potential adversaries who might themselves change according to the circumstances.

> The art of truly great popular leaders in all ages has consisted chiefly in not distracting the attention of the people, but concentrating always on a single adversary. The more unified the object of the people's will to fight, the greater will be the magnetic attraction of the movement

and the more tremendous its impact. It is part of a great leader's genius to make even widely separated adversaries appear as if they belonged to but one category, because among weakly and undecided characters the recognition of various enemies all too easily marks the beginning of doubt of one's own rightness. (From Hitler's *Mein Kampf*.)

It was a stroke of genius on the part of Hitler to find this common denominator in the Jews and Judaism. This enabled him to discover the "Jew" behind all his changing adversaries, sometimes behind Communism or Moscow, at other times behind Great Britain and the United States—in short, behind everybody and everything that at a given moment opposed his wishes or aroused his wrath.

Anti-Semitism served him also for two other purposes. National Socialism was fundamentally opposed to all concepts of international co-operation and universal catholicity; it destroyed the framework of a common humanity with common and absolute standards of law, truth and good, applicable to all men. National Socialism, therein following Nietzsche, regarded Christianity and prophetic Judaism, with their emphasis on the equality of all men under one common God and upon absolute standards of justice, as alien and inimical to the new hero ideal of the superrace, which was interpreted—not by Nietzsche, but by the National Socialists—as the true Germanic ideal. Judaism and the ethics of the Bible therefore stood in opposition to National Socialism.

National Socialism proclaimed the Germanic race as the new *corpus mysticum* on which the salvation of the world depended, as the embodiment of all nobility and creative genius and as the *Reich* ("empire") which must become the world-controlling *Reich*. This *Reich* necessarily had to have a *Gegenreich* ("Counter-*Reich*"), a counterrace that on a similarly worldwide basis would represent the antithesis of salvation and creative genius. So the Jewish people became the counterrace. National Socialism saw its duty not only in the destruction of this counterrace, but in the preparation of the German race for its real task of establishing the new world order. The third *Reich*—the hoped-for successor to the defunct second or Hohenzollern *Reich*—ruled by what Hitler called "the highest human species given by the grace of the Almighty to this earth," will have, by suitable education of the youth, in the future a generation mature for the ultimate and greatest decision on this globe. "The nation which will first take this road will be victorious," and become "one day the master of the globe."

The Jews were to be discriminated against not according to their religion but according to their "race." The fundamental contention of Hitler was that man is inescapably determined by his descent or "blood." Whoever was born from German parents remained a German forever in his nationality and character; whoever was born from Jewish parents remained forever a Jew by nationality and character. Thus Jews were declared, whatever their educational and environmental development, to be forever fundamentally different from Germans.

Hitler's racial theory was applied not only to Jews but also to people of German "blood" living in non-German lands. Germans who had emigrated from Germany and had become nationals of other countries, and even their descendants, were regarded as Germans, as *Stammesbruder* ("racial bretheren") and *Volksgenossen* ("national comrades"). Active propaganda was to be started among these Germans living in the "diaspora" (*Auslandsdeutsche*). If possible they were to be brought "home" into Germany, the true homeland of all Germans wherever they lived. If they could not be brought home, at least their loyalty to and activity for the German homeland was to be encouraged by all means. Study of German language and culture was to be promoted by all means among those Germans.

Rise to Power.—Working from these principles, Adolf Hitler was able to carry his party from its small beginnings in a beer cellar in Munich to a dominant position in world politics within 20 years. Among his more important collaborators were Alfred Rosenberg, the author of *Der Mythus des 20ten Jahrhunderts* ("The Myth of the 20th Century"; 1930), the most widely read book of the National Socialist movement besides Hitler's own *Mein Kampf;* Rudolf Hess, who helped Hitler write *Mein Kampf* during their internment in the fortress in Landsberg am Lech in 1924; Gregor Strasser, probably the most important of Hitler's collaborators, who separated from him in protest against the leader's opportunist policies and was killed in the blood purge of June 1934; his brother Otto Strasser, who in 1930 founded the Black front as a more radical wing opposed to Hitler; Gottfried Feder, who drew up the first program of National Socialism and was for several years its economic "expert" but thereafter receded into oblivion; Capt. Ernst Röhm, the founder and organizer of the SA or *Sturmabteilungen*, the National Socialist militia, who was purged in June 1934; Julius Streicher, who became famous through his anti-Semitic weekly *Der Stürmer;* Heinrich Himmler, the organizer and commander of the SS or *Schutzstaffel*, Hitler's personal elite guard, and of the Gestapo, the secret state police; Josef Goebbels, the master of National Socialist propaganda; Hermann Göring, the organizer of the German air force and controller of the German industrial mobilization; R. Walther Darré, the organizer of the National Socialist peasant policy; and finally Robert Ley, the leader of the German Workers' front.

It took 14 years for the N.S.D.A.P. to achieve power in Germany. It had been born at a time when it was only one of many semirevolutionary, reactionary and terrorist organizations springing up throughout Germany, composed of former officers and soldiers, students and other elements dissatisfied with the republican, democratic and peaceful order which seemed to dawn for Germany in 1919. That it survived and absorbed all others was due to Hitler's leadership and to the fact that Captain Röhm interested the *Reichswehr* in supporting Hitler. On Feb. 24, 1920, the N.S.D.A.P. drafted in Munich, the centre of its activities, a program of 25 points, which in 1926 was declared unalterable, but which in reality was very soon surpassed by developments. On Nov. 9, 1923, Hitler, supported by Field Marshal Erich Ludendorff, attempted his first *Putsch* in Munich, but it miscarried. Reaction was so firmly entrenched then in Bavaria, however, that Hitler was let off with only a formal punishment. The ensuing years of political and economic consolidation in Germany did not allow Hitler to make any considerable progress. The economic crisis at the beginning of the '30s, however, and the lack of energetic measures on the part of the government against the indefatigable propaganda to undermine democracy brought the first great success of the N.S.D.A.P. in the *Reichstag* elections of Sept. 14, 1930.

The *Reichstag* elections of Nov. 6, 1932, marked a temporary setback for Hitler; but an intrigue, started by Franz von Papen, prevailed upon the aged president of the German republic, Marshal Paul von Hindenburg, to name Hitler chancellor on Jan. 30, 1933. He was then only the head of a coalition cabinet of National Socialists and members of the conservative and nationalistic right. A fire in the *Reichstag* building on Feb. 27, 1933, gave Hitler the chance to rouse the spectre of a Bolshevik revolutionary danger and to hold the elections of March 5, 1933; though they gave the National Socialists only 44% of the votes, the antidemocratic totalitarian parties (National Socialists and Communists) had a majority following in Germany against the democratic republic, while the democratic forces were weak and without a clear program. Thus, the new *Reichstag*, meeting on March 21, 1933, in the garrison church in Potsdam, the historic receptacle of Prussian military spirit, "enabled" the government to assume dictatorial powers. From that moment on, the relentless process of *Gleichschaltung* ("co-ordination") began, and within a few months the German *Reich* had become a totalitarian state which was entirely identical with the N.S.D.A.P. in every concern of public or private life, and that meant with the will of its leader. (*See* GERMANY: *History*.)

Once firmly in power Hitler wished to secure his position against the left within his own party and against opposition from conservative circles without. Many of the adherents of National Socialism, especially in the SA, demanded radical social reforms. Hitler, on the other hand, wished to stabilize his revolution and to avoid alienating big business circles. The leader of the SA, Röhm, also wished to incorporate his semimilitary formations into the army, thus endangering Hitler's relationship not only with big business but also with the army leadership. The approaching crisis was heightened by the intraparty rivalries between Röhm on the one hand and Göring and Himmler on the other. The crisis was solved by the "blood purge" of June 30, 1934, when Röhm

and many other Nazi leaders were executed without trial. Hitler used the opportunity to have murdered a number of other prominent men whom he feared or disliked. Among these were Gen. Kurt von Schleicher, Hitler's predecessor as chancellor of the German *Reich*, and Gregor Strasser, who had been friendly to the trade-union movement.

National Socialism regarded Christianity from the beginning as an un-German faith. National Socialism was, in itself, a total creed centred upon Germanism and its unique and special mission bestowed upon it by nature and history. Though Hitler, for opportunist reasons, stressed his tolerance of the Christian church, or what he called "positive Christianity," true Christianity was incompatible with National Socialism as it is incompatible with Russian Communism, and the Nazis and the Communists knew it better and earlier than many Christians. The Vatican even signed a concordat with Hitler's government on July 8, 1933. But the concordat protected the Roman Catholic Church in Germany as little as it did the Protestant Church from constant interference and even persecution by the German authorities. Many Protestant ministers, though acknowledging the Nazi government's authority in all secular and political matters, denied it the right to interfere with the preaching of the gospel and with the internal administration of the church. They founded the *Bekennende Kirche* (confessing church), of which the best-known leader was Martin Niemöller.

The last conservative obstacle to Hitler's totalitarian police state was removed by the death of Hindenburg in his 87th year on Aug. 2, 1934. Hitler abolished the presidency and assumed the position of supreme commander. He now contented himself with the titles of *Führer* and *Reichskanzler*, leader and chancellor of the *Reich*. All troops and officials were immediately forced to take the oath of fidelity to Hitler personally. A plebiscite held on Aug. 19 confirmed these measures. Out of 43,529,710 votes 88.2% were cast in Hitler's favour.

In Power.—Outwardly, the Nazi party, following the pattern of the Communist party, was strictly centralized. Hitler's word was the supreme and undisputed command. The outward aspect of efficiency and unity was impressive. Nazi documents found after 1945 revealed, however, how much the party, like other totalitarian parties, was torn by internal dissensions and jealousies. There was constant overlapping and working at cross-purposes on all levels of the complex organizational system. The situation deteriorated when, after 1938 and especially with the progress of the war, the older, trained civil servants and army leaders were replaced by party members.

Opposition to the regime was broken either by outright terror or, more frequently, by the all-pervading fear of possible repression, even if no actual repression took place. As in the Soviet Union, all opponents of the regime were declared enemies of the state and of the people. An elaborate web of informers—often members of the family or intimate friends—working and reporting in secrecy imposed utmost caution on all expressions and activities. Justice was no longer recognized as objective but was completely subordinated to the alleged needs and interests of the "people." In addition, however, to the now debased methods of the normal judicial process, special detention camps were erected. In these camps—of which some, such as Dachau and Auschwitz (Oswiecim), achieved notoriety—the SS exercised supreme authority and introduced a system of sadistic brutality unknown in modern times and by far surpassing anything known in that respect in Fascist Italy or Communist Russia.

Resistance.—Church leaders participated actively in the resistance movement against Nazism. This movement never reached any popular dimensions and did not become active before the later years of the war into which Germany plunged Europe and the world. When the more rational leaders of the German army, together with members of the German official and educated class, recognized that Hitler was leading the Germans into defeat, they joined in a conspiracy that led to the attempt on July 20, 1944, to assassinate Hitler in his headquarters in East Prussia. The attempt miscarried, and the party took a frantic revenge on the conspirators. Many members of the German aristocracy and many high-ranking officers were executed, and the movement stressed again its antiaristocratic mass character as it had done at its beginning.

Turning Point; the War.—The history of National Socialism after 1934 can be divided into two parts of about equal length. The years between 1934 and 1939 were used to establish the full control of all phases of life in Germany by the party. The principal instrument of control was the unification of all the police, security and SS organizations under the direction of Himmler and his chief lieutenant, Reinhard Heydrich. The years between 1938 and 1945 witnessed the attempt to expand and apply the Nazi system to territories outside the German *Reich*. This attempt was confined, in 1938, to lands inhabited by a German-speaking population. In 1939 began the subjugation of non-German-speaking nationalities to the totalitarian Nazi police state. In 1945 this attempt collapsed.

The turning point in the brief but disastrous career of the Nazi regime in Germany was the year 1938. In that year the conservative influence in the two remaining bulwarks of an older, authoritarian but civilized Germany was ended—in the army and in the foreign office. In the same year, Hitler began German territorial expansion, carried through under diplomatic pressure, by "peaceful" means. In such a way he incorporated into the German *Reich* first the republic of Austria and then the Sudetenland (the German-speaking parts of the republic of Czechoslovakia).

By 1939 the military preparations, including the militarization of German life and education and the establishment of a war economy, had made such progress in Hitler's opinion that he could challenge the European order even at the risk of a second great war. On Aug. 23, Hitler, without consultation with his Italian and Japanese "allies," concluded a pact of friendship and nonaggression with the U.S.S.R. The pact contained a secret treaty between Germany and Russia partitioning Poland and dividing the whole of eastern Europe into spheres of influence. It was the first step opening the road into the heart of central Europe to Joseph Stalin and Russian Communism and the immediate prelude to World War II (*q.v.*), which began in Poland on Sept. 1.

To a certain extent World War II repeated the pattern of World War I: great initial German military successes; the forging of a large-scale coalition against Germany as the result of German pretensions and behaviour; the loss of the war because of German overreaching and conduct. (*See* also Germany: *History*.)

Ultimate Party Goals and Failure.—When Germany started World War II, it came as the logical outcome of Hitler's plans, known to the Germans since his publication of *Mein Kampf* (1926), and of his systematic preparations since 1933. From the beginning, National Socialism did not intend to establish a new order of authoritarianism and of inequality for Germany alone. Therein it again imitated Communism. Its dynamism was bound to expand and to spread. By its own nature it could not recognize any limits to its own volition, only limits set by opposed superior forces. Thus Hitler's first years were spent in preparing the Germans for the approaching struggle for world control and in forging that instrument which would enable Germany to establish its military and industrial superiority, and thus to fulfill its ambitions. With mounting success, the aims grew in quick progression. The first aim was to unite all people of German descent within their historic homeland on the basis of "self-determination." The next step foresaw the creation of a *Grosswirtschaftsraum* ("large economic unified space") or a *Lebensraum* ("living space"). (*See* GEOPOLITICS.) Thereby the Germans would acquire sufficient soil to become economically self-sufficient and militarily impregnable. There, the German master race or *Herrenvolk* would rule over a hierarchy of subordinate peoples and organize them with German ruthlessness and efficiency. The initial success of that plan in 1941 widened it into the vision of a hemispheric order that would embrace all of Europe, western Asia and Africa, and finally of a world order that would establish the principle of National Socialism all over the globe and give to mankind as a whole the "benefits" of a peace maintained by German bayonets and administered by a unified party bureaucracy.

The extreme neomercantilist economic self-sufficiency, protectionism and rejection of free trade, which received the new name

of *Wehrwirtschaft* ("defense" or "war economy"), was accompanied by an extreme cultural nationalist self-sufficiency and a resolute hostility against all western thought. The world rule to which National Socialism aspired would not only represent a military, economic and political domination, but equally an intellectual and moral leadership. The new world age or *Weltzeitalter* would be German and National Socialist at the same time.

These extravagant German hopes came to an end with Germany's defeat in 1945, after almost six years of war. Out of the ruins of National Socialist Germany there arose a divided and occupied Germany. The eastern provinces were put under Russian and Polish administration. The lands east of the Elbe, Saxony and Thuringia rivers, formed, under Russian occupation, a Communist-dominated state, called the German Democratic Republic. In western Germany, in close co-operation with the western democracies, the Federal Republic of Germany, under the chancellorship of Konrad Adenauer, came into being in 1949. Though a number of Germans remained faithful to National Socialism, its principles and dreams, even after Hitler's downfall, and though there were several attempts made to reorganize National Socialist groups in the Federal Republic of Germany, the political and mental climate there was not favourable to it, and it was hardly possible to speak of, or to expect, a revival of National Socialism in Germany.

NATIVISTIC MOVEMENTS. Nativistic movements are efforts by members of a society to build for themselves a more satisfying way of life by eliminating foreign persons, customs, material objects or ideas. Such movements belong to the larger class of revitalization movements, all of which aim to better the life of a society, but not all of which are nativistic. Sometimes the term nativistic movement is used loosely to denote any type of revitalization movement. The term is largely restricted in usage to anthropologists and is therefore commonly applied to primitive peoples in contact with western civilization. Similar events occur, however, in western societies and are frequently studied by historians and sociologists, who employ a different vocabulary (sect formation, messianic movement, revolution, religious revival).

Revitalization movements occur in societies which have been subjected to stress and whose culture has suffered disorganization. The typical process of a revitalization movement (and therefore of a nativistic movement) may be divided into six states: (1) the inspiration of the prophet; (2) the preaching of the inspired new code; (3) the development of an organization of disciples and followers; (4) the modification of the new code to fit local and temporal requirements; (5) the transformation of the society's culture along the lines of the new code; (6) the redefinition of the new code as traditional and the translation of the revolutionary organization into a conservative status.

Generally speaking, nativistic movements are religious; the new (or revived) religion itself details the changes to be made in such secular affairs as political organization, family structure, economic pursuits, war and international relations. Revitalization movements may bring about drastic changes in culture in very short periods of time.

Typologies of nativistic movements have been developed. One such analysis divides them into four groups: (1) revivalistic-magical; (2) revivalistic-rational; (3) perpetuative-magical; and (4) perpetuative-rational. Another typology is based on the extensiveness of the new code's coverage of cultural categories. There exist also various culture-area classifications based on typical forms taken by nativistic movements in various regions.

Thus Melanesia, and especially New Guinea, has been since the latter part of the 19th century the home of various native cargo cults (*q.v.*), which emphasize the belief that a ship, with the ancestors as crew and passengers, is approaching with a cargo of European goods. On its arrival European personnel and native custom alike are to be cast aside and the cult members will enjoy the full benefits of European civilization without the interference of white masters. Some believers destroy much of their property in anticipation of the new wealth. Africa south of the Sahara is the home of hundreds of separatist churches with similar goals.

South American Indians have for centuries produced *terre sans mal* (literally, "land without evil") movements, based on the belief in a promised land, either on earth or on some other plane, to which the people can by religious ritual or physical migration actually translate themselves.

North American Indians have tended to produce revivalistic doctrines, emphasizing the spiritual purity to be achieved by following ancestral (or at least distinctively Indian) ways of ritual and daily life. In 1805 in Ohio the Shawnee prophet Tenskwatawa preached rejection of European mode of dress, of the use of alcohol and intermarriage with whites, and certain Indian practices such as witchcraft. The movement became an antiwhite religious crusade lasting until the War of 1812. The so-called Ghost Dance of the 1870s and 1890s is the best known example of a North American Indian nativistic movement. Although the prophet Wovoka was a Paiute, the Dance itself spread widely among tribes west of the Mississippi river. In essence the doctrine was millenarian: the world was soon coming to an end and the new dawn would see all Indians, dead and alive, reunited to live according to more or less aboriginal standards; in the meantime, the Indians were to avoid any sort of conflict, to dance and in trances induced by continued dancing to meet ancestors (ghosts) and supernatural beings. The second Ghost Dance received special notoriety from its association with the Sioux outbreak of the 1890s.

Theories about the causes of nativistic and other revitalization movements generally emphasize that individual psychophysiological stress is elicited by cultural disorganization and in turn motivates the prophet and his followers. For example, some U.S. Negroes called Black Muslims (*q.v.*) preached racial separation (paradoxically agreeing with anti-Negro whites) in apparent response to such stress.

NATROLITE, a mineral species belonging to the zeolite group, is a hydrated sodium and aluminum silicate. Needlestone or needle zeolite are other names, alluding to the common shape (acicular habit) of the crystals, which are often very slender and are aggregated in divergent tufts. Larger crystals have the form of a square prism terminated by a low pyramid: the prism angle

being nearly a right angle, the crystals are tetragonal in appearance, though actually orthorhombic. There are perfect cleavages parallel to the face of the prism. The mineral also often occurs in compact fibrous aggregates, the fibres having a divergent or radial arrangement. Natrolite is usually white or colourless, but sometimes reddish or yellowish. The lustre is vitreous, or in finely fibrous specimens sometimes silky. The formula is $Na_2Al_2Si_3O_{10}\cdot 2H_2O$. The specific gravity is 2.2 and the hardness 5.5. The mineral is readily fusible. It is decomposed by hydrochloric acid with separation of gelatinous silica. *See* also ZEOLITE.

NATSUME SŌSEKI (pseudonym of NATSUME KINNOSUKE) (1867–1916) is by general consent the outstanding figure of modern Japanese literature. He was graduated from the English literature department of Tokyo university in 1893 and from 1900 to 1903 studied in England.

The influence of English literature is most conspicuous in his earliest published works, the satirical *Wagahai wa Neko de Aru* ("I Am a Cat," 1905) and *The Tower of London* (1905), but it can be traced through most of his later writings as well. To this knowledge of European literature Natsume brought an unusual understanding of Japanese *haiku* (*see* JAPANESE LITERATURE) and Chinese poetry, in both of which he excelled. His writings, indeed, represent one of the rare successful blendings of western novelistic techniques with Japanese traditions.

Natsume's reputation as a novelist was firmly established with *Botchan* (1906; Eng. trans., in part, by Watson, in D. Keene, *Modern Japanese Literature,* 1956) and *Kusamakura* (1907). In 1908 he left his post at Tokyo university, where he had been teaching English since 1903, in order to devote himself entirely to his novels, which were published serially in the *Asahi* newspaper. *Mon* ("The Gate," 1910) contains a first enunciation of Natsume's concern with egoism in human relations, a theme that was treated with increasing profundity and incisiveness in each of his successive novels and finally resolved in his principle of *sokuten kyoshi,* "to follow Heaven and depart from the self." *Kokoro* (1914; Eng. trans. by E. McClellan, 1957) and *Meian* ("Darkness and Light," unfinished at his death in 1916), perhaps Natsume's finest novels, deal largely with this same theme.

Natsume also wrote literary criticism, diaries and works, such as *My Individualism* (1915), in which he stated his philosophy. He died on Dec. 9, 1916, leaving behind many devoted disciples.

NATTA, GIULIO (1903–), Italian chemist, co-winner, with K. Ziegler (*q.v.*), of the 1963 Nobel prize for chemistry for his fundamental work on olefin polymers, was born at Imperia, near Genoa, on Feb. 26, 1903. He obtained his doctorate in chemical engineering in 1924 at the Polytechnic institute of Milan. He held successively the chairs of general chemistry at the University of Pavia, physical chemistry at Rome university and industrial chemistry at Turin university, returning in 1938 to the Milan polytechnic as professor of industrial chemistry and director of the industrial chemistry research institute.

In industrial chemistry he was mainly interested in those organic reactions that proceed only at moderate or high pressures, with special concern for the kinetics and thermodynamics of the processes and the structure of heterogeneous catalysts. His work came to form the basis for the modern industrial syntheses of methanol, formaldehyde from methanol, butyraldehyde from propylene and carbon monoxide, succinic acid from acetylene and carbon monoxide, and synthesis gas.

He became best known for his discoveries after 1953, when he started intensive studies on macromolecular chemistry. These were initiated by knowledge, obtained through a licence arrangement between Ziegler and the Italian company Montecatini (of which Natta is a consultant), of Ziegler's discovery of the low-pressure synthesis of linear polyethylene of high molecular weight. By applying the Ziegler catalysts to the polymerization of propylene, Natta found in early 1954 that part of the polymer was highly crystalline, recognized that it must have been built up with a considerable degree of uniform three-dimensional, or steric, order and proved the structure by application of X-ray methods. The name "isotactic" (same shape) was coined to describe this particular symmetrical structure. Natta realized that the surface of the catalyst must also be highly regular to give rise to the isotactic polymer and then discovered variants of the Ziegler catalyst system that made possible the high-yield isotactical polymerization of propylene and other olefins.

The isotactic polymers, especially polypropylene, showed remarkable and unexpected properties of commercial importance, such as high melting point, high strength and the ability to form films and fibres. It was recognized that a new type of polymerization, termed co-ordination polymerization, was involved in these syntheses. In it the growth of the polymer chain occurs by insertion between the existing chain and the solid surface of the catalyst, which controls the geometry of the reaction. (In most earlier polymerization methods, the catalyst is remote from the growing end of the chain and has therefore no effect on reaction geometry.)

After 1954 Natta studied the mechanism of the reaction, its stereospecific aspect and the synthesis of many hitherto unknown catalysts and polymers, especially cis-1, 4-polybutadiene and the copolymer of ethylene and propylene, both of which were regarded as potentially important synthetic rubbers. (H. W. B. R.)

NATTIER, JEAN MARC (1685–1766), French painter, known for his portraits of the ladies of Louis XV's court in mythological attire, was born on March 17, 1685, in Paris, the son of Marc Nattier, a portrait painter, and of Marie Courtois, a miniaturist. He received his first instruction from his father and took the first prize at the Paris academy at the age of 15. He refused to study at the French Academy in Rome and in 1715 went to Amsterdam, where Peter the Great was then staying. There he painted portraits of the tsar and his wife, the empress Catherine, but declined an offer to go to Russia. Between 1715 and 1720 he painted the "Battle of Poltava" for Peter the Great, and the "Petrification of Phineus and of His Companions" (Tours museum), which led to his election to the Academy. The financial collapse of 1720 all but ruined Nattier, who was obliged to turn to portraiture. Notable examples of his straightforward approach are the "Marie Leszczinska" at the Dijon museum and "The Artist Surrounded by His Family," dated 1730.

Among his pictures are the "Magdalen," at the Louvre; "La Camargo" and "A Lady of the Court of Louis XV," at Nantes; the "Head of a Young Girl," at Orléans; and "Mme de Pompadour," at Marseilles. The Versailles museum owns a group of two ladies, and the Dresden gallery, a portrait of the Maréchal de Saxe. In the Wallace collection are "The Comtesse de Dillières," "The Bath (Mlle de Clermont)," "Portrait of a Lady in Blue," "Marie Leszczinska" and "A Prince of the House of France." Four portraits of the daughters of Louis XV, with the attributes of the four elements, are in the Museo de São Paulo, Braz.

He died in poverty in Paris on Nov. 7, 1766.

NATURAL (in music): *see* ACCIDENTALS.

NATURAL GAS: *see* FUELS: *Gaseous Fuels.*

NATURALIZATION: *see* NATURALIZATION LAWS; CITIZENSHIP.

NATURALIZATION, PLANT AND ANIMAL. The term naturalization refers to the persistence of a species in the wild state in an adopted habitat where it eventually settles down as part of the local flora or fauna. The species in any region may be broadly classified as endemic or native and exotic or foreign.

The former are those species that either originated in that region during the course of evolution or that arrived there by natural migration from other centres of origin. They constitute the primeval flora and fauna of the region. The exotic group consists of all other species, the criterion being their observed introduction into that region. Because historical records are inadequate, some species may be misclassified as endemic, especially where civilization has been flourishing since ancient times. Such mistakes occur least in those regions recently colonized by the European: *e.g.*, Australia and New Zealand, where records are scientific and the endemic flora and fauna are fairly unique. The exotic species of a region include some or all of the domesticated species, whose persistence is entirely dependent upon the care of man; sporadic species that, though able to multiply, cannot maintain themselves in their new habitat but have to be steadily introduced afresh; and finally, the naturalized species. In the process of naturalization these species undergo somatic and genetic changes and often assume new population dynamics in their new environment, which in turn reacts on the ecology of the new habitat. (*See* also ACCLIMATIZATION.)

Introduction and Establishment of New Species.—In their movements about the world, men, both by accident and by design, have broken down many barriers that previously prevented the natural migration of species. The soil used in ships as ballast, vegetable material used as packing for goods, animal fodder and commercial seed supplies of crop and pasture plants all contained weed seeds which were distributed throughout the world. The ubiquitous naturalization of the black rat, brown rat, house mouse, European cockroach and housefly was directly effected by trade. For these animals the ship was not only a means of transport but also an environment to which they became naturalized, which allowed them to spread the more readily. Subsequently air travel removed the limitation of time that had hitherto obstructed the distribution of species unable to survive the long sea voyages. With the airplane the African malaria mosquito, *Anopheles gambiae*, gained entry into Brazil, where it soon became naturalized.

Many plants and animals were deliberately introduced from one country to another, some for domestication in the new country, and others directly for naturalization. Some plant species were brought in to grace the gardens of the colonists; others, such as the prickly pears in South Africa, the Malagasy Republic, India and Ceylon, and the eucalypti in California, were introduced for economic purposes. Most of the mammals, birds and fish were imported for the purpose of naturalization to provide game and to enrich the sources of meat and fur. In Australia and New Zealand, owing to the intense activity of the many acclimatization societies during the 19th century, almost every animal, bird or fish species of European and North American origin of interest to sportsmen was introduced with a view to attempting naturalization. Unfortunately, many of these introductions subsequently succeeded only too well (*see* below).

The second step toward naturalization is the establishment of a breeding stock big enough to ensure an initial reproductive rate greater than the initial death rate. The minimum size of the breeding stock depends on the breeding system and, in some cases, on the behavioural pattern of the species. For plants that reproduce vegetatively or by self-fertilization, and for those animals that can reproduce parthenogenetically, such as many species of insects, one specimen suffices. But for species that require cross-fertilization for reproduction at least two and often many more specimens are necessary to ensure establishment. The more social and potentially fertile a species, the smaller the population required for establishment. (J. R. Philip has given an excellent mathematical treatment of this.) According to G. M. Thomson, most plants that become naturalized are capable of self-reproduction and are prolific seed bearers.

In many cases therefore, establishment may be a limiting factor to naturalization. An introduction may fail partly because it consists of too few individuals. A later, ampler, introduction may well lead to naturalization. This happened with the rabbit in Australia and New Zealand, where several introductions were made before one became established. The naturalization of an introduced species may be limited indirectly by inbreeding degeneration, which reaches a peak in the second generation after introduction and may lead to failure, especially for species of low reproductive potential.

Ecology of Naturalization.—*Changes Effected by Man.*—When men colonize a new region, it becomes radically transformed. Lumbering, clearing, leveling, draining, firing, cultivating, stocking and many other tasks performed to make the land more habitable alter its physical and ecological aspects so much that many of the indigenous species succumb to or emigrate from the changed environment. In the old world these changes occurred long ago, so that many species have become adapted to the new habitats produced by the activities of man. Such species are commensals of civilization. Those that emigrated with the European to new continents were thus able to naturalize in the somewhat similar environments created by man in his new habitat. P. Dansereau in Canada and G. M. Thomson in New Zealand have observed that most naturalized plant species are of European origin, mainly weeds of cultivation or plants growing in waste places in both their original and adopted habitats. In classifying the 387 plant species that had become naturalized in the environs of Auckland, N.Z., T. F. Cheeseman found that 280 species were of European origin, only 14 North American and 19 Australian. This confirms that species best adapted to living in association with the European are most likely to become naturalized in regions colonized by him. Animal species in a close association with man in their original habitats maintain this close association in their new habitats. Thus, as western civilization spread, the housefly, the black and the brown rats, the cockroach and the English sparrow became naturalized.

Despite their worldwide distribution, domesticated crop plants have failed to naturalize. For in the process of being adapted as crops these plants have been much changed genetically through selection in an environment where competition from other species is minimized and inroads by animal pests and plant pathogens are constantly guarded against. Without man's care and protection, these species cannot survive. In contrast, many pasture plant species, *e.g.*, grasses and legumes, have been able to naturalize, no doubt because they have not been so highly selected.

Some domestic animal species that have escaped have been able to naturalize in exotic environments. G. G. Simpson discusses the spread of the horse on the American continent after its introduction by the conquistadores, Spanish explorers and colonists in the 16th century. Similarly, brumbies, the wild version of the domesticated horse in Australia, have spread to and inhabit some of the remote mountain areas. Escaped pigs and beef cattle both readily naturalize. Some of the wild pigs ranging over parts of New Zealand are probably the distant progeny of the pigs released by Capt. James Cook late in the 18th century. Although nominally domesticated, the beef animal raised on the open range in parts of the Americas and Australia really lives in the feral state, and may thus be considered as naturalized.

A few plant species whose original habitat is still primeval, uninfluenced by man's activities, have been able to naturalize in other regions, *e.g.*, a number of *Eucalyptus* species introduced from Australia into California to provide a source of hardwood. *Lantana* species, natives of Central America, have become naturalized in Hawaii, India and Australia, and the North American Monterey pine has succeeded in New Zealand. But none of these species has been able to enter into the primeval habitat in its country of adoption. Only in rare instances have plant species naturalized in the primeval habitat; P. Dansereau mentions the European flowering rush (*Butomus umbellatus*) that has colonized the silt margins of the St. Lawrence river system.

Naturalized faunal species are usually not so restricted to disturbed habitats as are the naturalized plant species. In New Zealand, the red deer, fallow deer, moose, elk, chamois and the Himalayan goat have all readily naturalized in the primeval mountain areas (G. M. Thomson). The various European trout species, carp and European perch have also been able to naturalize under primeval conditions of the streams in North America, Australia and New Zealand.

Response of Naturalized Species to the New Environment.—Physical aspects of the environment tend to be similar for the original and the new habitat for most naturalized species, since these are usually transposed into a climate similar to the original one. But the biotic aspects are often very different, especially for the species that naturalize in the primeval environment of the new region. While naturalized species have to cope with new competition, they often have the great advantage of no longer suffering the depredations of their original natural enemies. Sometimes they multiply so far as to attain plague proportions, which not only disturbs the previous ecological balance but also often disastrously upsets the economy of those who had introduced them.

Some species become physiologically more vigorous through naturalization. G. M. Thomson records the case of the European water cress, which is normally 2 to 4 ft. long in Europe but commonly reaches lengths of 12 to 14 ft. in New Zealand. Similarly, the spear thistle, which is 2 to 5 ft. tall in England forms impenetrable thickets some 7 ft. high in New Zealand. In its new habitat a naturalized species will eventually undergo evolutionary changes, at a rate depending on the genetic diversity of the introduced species and on its breeding system. Mutations and, for outbreeding species, genetic reassortment should restore normal levels of genetic variation in the naturalized species. Little evidence for evolutionary changes following naturalization has yet been obtained. Some changes in morphology and physiology, especially qualitative ones, can be shown to have a genetic basis, if the evolutionary transition occurs while the population is being observed. Otherwise comparative studies are required of representative samples of the naturalized and the endemic populations in a common environment; failing these the more subtle quantitative changes would remain unobserved.

M. A. C. Hinton cites a genetic change in a naturalized population of the black rat (*Rattus rattus*). In its native habitat of southeastern Asia, the black rat has a yellow to red-brown back and a white belly. It was introduced to western Europe during the crusades. Later records show that the now prevalent black form arose sometime during the 16th century. Similarly the black variety of the brown rat (*Rattus norvegicus*), which naturalized in western Europe during the 18th century, was first recorded in 1837 in Ireland. H. N. Barber found a genetic colour change in the naturalized European rabbit (*Oryctolagus cuniculus*) in Tasmania. Over most of the island the normal agouti variety is predominant. However in the rain-forest area in the north, which has been occupied by the rabbit only since clearing operations began in the 1920s, the rabbit population contains pockets with as high as 35% black rabbits.

Response of the Endemic Flora and Fauna.—Where naturalized species occupy disturbed habitats their intrinsic effect cannot be isolated from that caused by man's transformation of the environment. Only the cases involving naturalization in the primeval environment can be assessed. Native species may experience not only direct competition from the newcomer, but also more remote secondary effects.

According to G. M. Thomson the naturalization of perch, trout and carp in New Zealand waterways has led to the extinction of many endemic prey species such as the native crayfish (*Paranephros*) and the freshwater amphipods. The native grayling, kokopu, minnow and smelt also became extinct in some places, either because they fell prey to the naturalized European fish species or because they were starved out of existence by them. Some native species of plants with edible starch storage organs have been completely eaten out in parts of New Zealand by the wild pig and rat.

In some cases the endemic species have profited by the naturalization of exotic species. The New Zealand long-tailed cuckoo (*Urodynamis taitensis*) thrives upon many of the smaller birds of European origin and is becoming more prevalent. Some endemic plant-eating insects of New Zealand have taken to some naturalized plants species. The common grass grub (*Odontria zealandica*) feeds on naturalized and pasture species of European grasses and has increased sufficiently to become a serious agricultural pest.

Examples of Untoward Naturalization.—*Naturalization of the Rabbit.*—The most spectacular case history of animal naturalization is that of the European rabbit. Being highly adaptable, it has successfully colonized in places ranging from equatorial Uganda to the bleak Tierra del Fuego, Chile, and from the rain forests of northern Tasmania to the semidesert areas of inland Australia.

The rabbit, a native of Mediterranean Europe, spread to England during the 12th century, probably having been taken there by the Normans from France. It was highly prized for its meat and fur—reasons why it was introduced to Australia, New Zealand and Chile. Not until recent times has the rabbit been duly recognized as a destroyer of crop and pasture.

After a number of unsuccessful attempts to naturalize rabbits in Australia, an introduction of 24 wild rabbits from England, released near Geelong, Victoria, in 1859, established a population that in the short space of 70 years spread over most of the continent in such high numbers as completely to eat out large sections of the semiarid pastoral country. Removal of plant cover exposed these lands to wind erosion. In the wetter areas, overgrazing and burrowing in the hills caused serious water erosion. The loss to agricultural and pastoral production led to rabbit control measures, which, after the mid-19th century, became an integral part of rural management and were enforced by legislative action after 1876.

Naturalization of the Prickly Pear.—The widespread introduction of the prickly pear, likewise, caused much economic damage. The prickly pear belongs to the cactus genus *Opuntia*, native of the arid warm temperate-to-subtropical America. It was once important for the now obsolete cochineal dye industry, as a source of food for the cochineal insect that produced the dye, and had therefore been widely transplanted. It was introduced into the Mediterranean region soon after the discovery of the new world, where it naturalized in waste places and was valued for its fruit. It is also naturalized in South Africa, India, Ceylon, the Malagasy Republic and Australia. While the fruit forms an essential item of the natives' diet in the Malagasy Republic, its naturalization in Australia was disastrous. Millions of acres of good pastoral land in Queensland and northern New South Wales became densely infested with the prickly pear. The situation appeared hopeless until the advent of biological control methods.

Biological Control.—Grave economic threats may result from accidental or uncontrolled naturalization of plants and animals. Various governmental authorities have therefore established quarantine facilities and regulations. To cope with already naturalized species, biological controls have been developed. These rest on the assumption that where naturalized species multiply excessively this happens only because the new habitat lacks their natural enemies: if these are introduced, a naturalized species that has reached plague proportions may be cut back to the level of reproduction that obtains in its country of origin. There are attendant risks in that the predator species itself may in turn become a pest. A thorough prior study must be made of the likely predators, to ensure they will not attack species of value.

The naturalization of the fox in Australia, following its introduction in 1868 for the dual purpose of controlling the rabbit and providing sport, was a total failure as far as the former aim was concerned. Instead the fox itself became a serious pest, preying upon the native marsupials and birds. Similarly, the introduction of the butterfly *Thecla echion* into Hawaii to control *Lantana* was unwise because the butterfly also attacks the egg plant. In the long run biological methods afford by far the most economic way of controlling naturalized plant and animal species that have become pests. Two examples are outstanding: myxomatosis and the European rabbit; and cactoblastis and the prickly pear.

Myxomatosis and the Rabbit.—Myxomatosis is a rabbit disease caused by infection with the myxoma virus. The myxoma virus is endemic to the American continent, where the Brazilian wild rabbit (*Sylvilagus brasiliensis*) is the only natural host known. The virus is a specific parasite of the rabbit and is transmitted by the mosquito and the rabbit flea. Typical of well-adjusted parasites, the myxoma virus induces only a very mild form of the disease in the Brazilian wild rabbit. However, when contracted by the

European wild rabbit, myxomatosis proved to be highly lethal, the mortality being as high as 99.8%.

The first suggestion that this disease should be tried out for controlling the rabbit in Australia was made in 1918. Some myxoma virus was accordingly sent to Australia in 1926, but the disease failed to establish itself. After extensive host range studies (conducted by Sir Charles Martin at Cambridge, Eng., and sponsored by the Australian government) showed that only rabbits were susceptible to myxoma virus, further laboratory and field trials were made in Australia between 1936 and 1943. But the disease established itself only locally in some of the release areas, and failed to develop into an epizootic. Nothing further was done until 1950, when the Australian government requested the Wildlife Survey section of the Commonwealth Scientific and Industrial Research organization to try introducing the disease again.

Seven liberations of the virus were made in 1950, one of which was successful and the disease spread rapidly. By the third year of the epizootic, the rabbit population in southeastern Australia had been reduced by about 80%.

The myxoma virus has since been released in a number of other countries. The European epizootic was started by a private individual, A. Delille, who obtained some myxoma virus from a laboratory in Switzerland and in June 1952 injected two rabbits with it. These were released on his private estate near Paris, where, within a month, almost all the rabbits were wiped out. The French authorities tried to stamp out the disease, but by the end of 1953 myxomatosis had spread throughout France and into Belgium, Luxembourg, the Netherlands, Germany and Spain and had even crossed the channel. In 1954 the disease was successfully established in Tierra del Fuego by the Chilean government. In New Zealand and Tasmania, myxomatosis failed to assume epizootic proportions, in spite of repeated attempts to establish it.

It is believed that the relief from the rabbit problem afforded by myxomatosis may be only temporary. In Australia less virulent strains have come to the fore. Mortality has declined from 90% to 30% in seven years. Further attempts to reestablish control by the release of new virulent strains of myxoma virus have failed.

Cactoblastis and the Prickly Pear.—In 1920 the Commonwealth Prickly Pear board was formed in Australia to investigate the possibility of biological control of the prickly pear. Insects (both local and foreign) that attack the plant were studied. About 50 species from the United States were selected and sent to Australia for further tests under quarantine. Twelve of these were found suitable: they attacked no other plants. Moreover, during quarantine any parasites from abroad were wiped out. Some of these species naturalized and multiplied rapidly at the expense of the prickly pear. Then in 1925, a moth, *Cactoblastis cactorum*, was introduced from Argentina, multiplied in quarantine and set free in 1926. From 1927 onward eggs were collected in the field for distribution to other localities. By 1933 the last stand of the original infestation had been destroyed. Both plant and predator survive at low levels in a dynamic balance. Thus 22,000,000 ac. of land were reclaimed for agriculture.

Summary.—Man has had cause to regret some of his introductions. In addition to the unfortunate cases of the rabbit and prickly pear in Australia, man is responsible for the starling surfeit in the United States and the widespread depredations of the Indian mongoose in Hawaii and parts of the West Indies. These large-scale but unplanned experiments in ecology have alerted many to the dangers inherent in thoughtless programs of plant and animal introductions. But on the other hand man could not survive in his present state without reliance on the introduced cultigens, improved crop plants, that serve as his basic food. And life would be less pleasant without the plants and animals that have been widely introduced for sport, aesthetics or sentiment. *See* also MIGRATION, ANIMAL.

NATURALIZATION LAWS. Naturalization is the act of investing an alien with the status of a national in a given state. It takes place whenever a new nationality is acquired by a person after his birth. It may be accomplished as the result of voluntary application, special legislative direction, marriage, parental action or annexation of territory. The conditions under which the privilege of naturalization will be granted are fixed by the laws of each nation. International law, however, imposes some limits on the power of a state to naturalize persons, especially nonresidents.

UNITED STATES

The constitution of the United States, art. 1, sec. 8, clause 4, authorized congress to "establish an uniform Rule of Naturalization. . . ." Congress fulfilled that mandate by enacting naturalization statutes, beginning in 1790, to establish the conditions under which aliens might be admitted to citizenship. The opportunity to become naturalized is not a constitutional right but a statutory right contingent upon establishment of the requisite facts. The requirements for naturalization have never been exacting, and the consistent national policy has been to encourage the naturalization of all qualified aliens. That policy aided in developing the strength of the United States, whose growth resulted largely from the contributions of millions of immigrants and their descendants. It marked a departure from existing British policy under which naturalization was only sparingly granted by special acts of parliament.

Naturalization by Court Process.—The principal method of acquiring a new nationality is through voluntary application in the manner provided by law. Most countries authorize the grant of citizenship by an administrative official. In the United States, however, naturalization from the first has been a function of the courts. Congress conferred power to grant naturalization upon all federal district courts and upon state courts of unlimited jurisdiction that have a seal and a clerk. An applicant may appeal to the higher courts from a decision rejecting his petition. The government is a party in every naturalization case and may appeal when it deems that naturalization was improperly awarded.

The principal disqualification for naturalization was directed against some racial groups. Originally the statutes permitted the naturalization only of "free white persons." In general, since 1790, naturalization legislation has extended rights to greater segments of alien people.

In 1952 the Immigration and Nationality act of that year (popularly known as the McCarran-Walter act) was passed over President Truman's veto. It was a comprehensive codification and revision of prior immigration, naturalization and nationality laws. It provided that "The right of a person to become a naturalized citizen . . . shall not be denied . . . because of race or sex or because such a person is married." But aliens identified with certain proscribed organizations, activities or beliefs at any time during the ten years immediately preceding the petition for naturalization, or after filing the petition and before taking the final oath of citizenship, were disqualified. However, these disqualifications did not apply if the alien could prove that his membership or affiliation in a proscribed organization was involuntary; or that it terminated before he reached the age of 16; or that it was by operation of law; or was for the purpose of obtaining employment, food or other essentials of living. Naturalization cannot be granted to an alien who claimed exemption from military service on the ground that he was an alien. Nor can it be granted to a person who, during time of war, was convicted of desertion from the armed forces of the United States or of leaving the country to avoid the draft.

Several basic qualifications always have been prescribed, vir-

tually without change, in the statutes relating to naturalization. It is important to bear in mind that these are general requirements which often have been modified with respect to special persons whom congress desired to favour.

First, the applicant for naturalization must be at least 18 years old and must have resided in the United States for at least five years following a lawful admission for permanent residence. He must have been physically present in the United States for periods totaling at least half of the five years preceding the filing of his petition for naturalization. Lesser periods of residence, and in some cases no fixed residence requirements, are prescribed for naturalization applications by wives and children of U.S. citizens, former citizens and persons who serve in the armed forces or the merchant marine and other special categories. Absence from the United States for a period of more than six months raises a presumption that the residence in the United States has been abandoned; a year's absence is regarded as conclusive. Exceptions are made for persons employed abroad by the U.S. government and certain U.S. organizations, provided the employees obtain prior approval from the attorney general.

Second, the applicant must establish that he is, and was during the requisite period of residence, a person of good moral character. Persons who have committed serious crimes during that period generally are barred.

Third, the applicant must establish that he is, and was during the requisite period of residence, attached to the principles of the constitution of the United States and was well disposed to the good order and happiness of the United States. The latter requirement was designed to exclude from citizenship aliens hostile to the United States and its institutions. For many years the courts also interpreted this requirement as forbidding the naturalization of conscientious objectors to military service. In 1946, however, the supreme court, reversing its earlier holdings, determined that conscientious objectors might be naturalized (*Girouard* v. *United States*, 328 U.S. 61 [1946]). The 1952 act permitted naturalization of persons who refused on religious grounds to bear arms. Even if a conscientious objector does not promise to bear arms, he may be compelled to do so after naturalization.

Finally, the applicant generally must meet several educational requirements. He must demonstrate an understanding of the English language, including an ability to read, write and speak words in ordinary usage. He must sign the petition for naturalization in his own handwriting if he is physically able to write, and must demonstrate some understanding of the constitution and form of government of the United States.

While the ultimate power to grant or deny naturalization is conferred upon the courts, the law vests in the immigration and naturalization service of the department of justice administrative supervision over the naturalization process. The service, headed by a commissioner of immigration and naturalization, is under direction of the attorney general and is organized into 16 district offices as well as numerous suboffices throughout the United States. The immigration and naturalization service is given broad legal authority to receive applications, interrogate the applicants and their witnesses and make recommendations to the naturalization courts. This administrative function is designed to aid the courts in discharging their responsibilities in granting or denying naturalization.

Naturalization Process.—The naturalization process begins with the filing of an application or petition for naturalization with the immigration and naturalization service. A declaration of intention, popularly known as "first papers," is no longer required. Prerequisites to the filing of such an application are attainment of the age of 18 and lawful entry into the United States for permanent residence. The procurement of an official certificate establishing such entry is not necessary. Proof of lawful entry can be made directly from visa records.

The next step is a personal investigation of the alien by the immigration and naturalization service unless the investigation is waived by the district director of the service. The applicant then files a petition for naturalization in the office of the clerk of the court. The petition is signed and sworn to by the petitioner and his two witnesses. The heart of the naturalization procedure then takes place; *i.e.*, a preliminary examination by an employee of the immigration and naturalization service. The petitioner is then notified to appear before a judge for final hearing. At the final hearing a representative of the immigration and naturalization service appears and must recommend either that the petition be granted or that it be denied.

If the court grants the petition, the petitioner takes an oath in open court forswearing all foreign allegiance and pledging allegiance to the United States. The judge then signs an order admitting him to citizenship. Thereafter the newly invested citizen receives an official certificate of naturalization. The fee of $10 must be paid to the clerk of court at the time of filing the petition for naturalization. No further fee is prescribed for the final hearing or for issuance of the certificate of naturalization.

A naturalized citizen acquires status equal to a native-born citizen, except that he is not eligible to become president of the United States. However, even after naturalization is finally granted, it may be revoked through a judicial proceeding. The statute authorizes such revocation only on the ground of "concealment of a material fact or . . . willful misrepresentation." A "material fact" would seem to be one which, if known at the time of naturalization, would have prevented the granting of the petition. This would include insufficient period of residence, illegal entry and any fact showing lack of good moral character, such as a past criminal record.

Other Forms of Naturalization.—Another method of acquiring citizenship is by derivation through a husband or parent. Prior to Sept. 22, 1922, marriage to a U.S. citizen or the husband's naturalization conferred U.S. citizenship upon an alien wife. The Cable act of that date abolished the joint citizenship of husband and wife and enabled a wife to choose her own nationality. Citizenship status previously acquired, however, was not affected.

A child under 16 years of age acquires U.S. citizenship through the naturalization of his parents if the child is residing in the United States or if he subsequently resides in the United States before his 16th birthday. Derivation takes place only if both parents become naturalized, unless one parent is dead or there has been a divorce or legal separation, in which event the naturalization of the parent having legal custody is sufficient.

A person who has acquired U.S. citizenship by derivation may apply to the commissioner of immigration and naturalization for a certificate recognizing that status. The fee for this application is $5. Upon presentation of proof establishing a valid claim to U.S. citizenship, the commissioner issues a certificate of citizenship to the applicant.

Congress also may grant citizenship by special legislation. In some instances, so-called private bills have been enacted conferring citizenship rights upon named individuals. Much more common has been the award of collective naturalization to large groups of noncitizens, particularly the inhabitants of U.S. territories and possessions.

The nationality status of the inhabitants of certain acquired territories was fixed by the treaty-making power of congress. Statutes have from time to time effected collective naturalization either prior to or upon the admission of territories to statehood. Such action was taken in territory acquired under treaties concluded with Great Britain (territory of Michigan, 1794, 8 Stat. 116); France (Louisiana, 1803, 8 Stat. 200); Spain (Florida, 1819, 8 Stat. 252); Mexico (Guadalupe Hidalgo, 1848, 9 Stat. 922; Gadsden, 1853, 10 Stat. 1031); Russia (Alaska, 1867, 15 Stat. 542); and Denmark (Virgin Islands, 1916, 39 Stat. 1706).

In the absence of definite treaty stipulations, citizenship has been conferred upon inhabitants of acquired territory by legislative enactments. In this category were the Hawaiians (act of April 30, 1900, 31 Stat. 141); Puerto Ricans (sec. 5 and 5[a], act of March 2, 1917, as amended, and sec. 202, Nationality Act of 1940); Virgin Islanders (act of Feb. 25, 1927); Guamanians (act of Aug. 1, 1950, 64 Stat. 385); other outlying possessions, provided one parent of the child born in such possessions is a citizen who has been physically present in the United States or in one of its outlying possessions for at least one year prior to the birth of the child (Immigration and Naturalization act of 1952). Finally,

U.S. citizenship was conferred collectively through the political incorporation of the original states into the United States; in the case of Texas, upon its annexation and direct admission into the union; upon American Indians born in the United States through special legislation on June 2, 1924; and upon a member of an "Eskimo, Aleutian, or other aboriginal tribe" by the 1952 act.

Full status as U.S. citizens, however, was not conferred on all the inhabitants of U.S. territorial possessions. Complete citizenship rights were extended to inhabitants of Alaska and Hawaii (before statehood), and to Puerto Rico, the Virgin Islands and Guam; but the natives of other possessions such as American Samoa were regarded as noncitizen nationals of the United States, entitled to U.S. protection but not to full citizenship status.

(J. Mak.; E. G. H.)

COMMONWEALTH OF NATIONS

United Kingdom.—General statutes providing for the naturalization of aliens were in force in England, Scotland, and Ireland in the 17th and early 18th centuries but were repealed or fell into disuse during the latter century. Thereafter naturalization was by private act of parliament. The practice of including the names of groups of applicants in a single private act made obsolete the ancient institution of letters of denization. The Aliens act, 1844, which reintroduced general naturalization under administrative regulations rather than by statute, rendered private naturalization acts unnecessary. Instances of such acts became increasingly rare, the last being, apparently, that passed for the benefit of Lord Acton in 1911.

In the history of the United Kingdom, naturalization or denization has always been by grant; *i.e.*, it has been a matter of executive discretion rather than, as in the United States, the right of an applicant who can satisfy customary or statutory requirements. British naturalization, further, has been traditionally a local matter. Thus naturalization in Ireland or in a colony generally conferred no status valid in Great Britain and did not entitle the naturalized person to British protection abroad. This state of affairs persisted into the 20th century, although it appears to have been generally accepted that a person naturalized in the United Kingdom under the act of 1844 or under its successor, the Naturalization act of 1870, was entitled to the status of a British subject in any colony. By the British Nationality and Status of Aliens acts, 1914–43, however, an imperial certificate of naturalization was introduced. It could be granted in the United Kingdom with the consent of the secretary of state, in India, in any colony and in such of the self-governing dominions as adopted the act; it could be granted without the concurrence of the secretary of state. Despite this creation of a common status of British subject by naturalization comparable to the common status of British subject acquired by an individual through his own birth or the birth of his father anywhere within the territories under the dominion of the crown, local naturalization persisted. Thus in the Union of South Africa purely local provision was made in 1924 and 1928 for the German population remaining in South West Africa. Local naturalization continued also in India because of the inability of some applicants to satisfy the requirement of an adequate knowledge of English imposed in connection with the grant of imperial certificates. Both in the United Kingdom itself and in New Zealand, special provision of an exclusively local character was made for the members of the Free French forces during World War II.

The act of 1914 was in any event repealed by the British Nationality act (1948) of the United Kingdom and by the corresponding legislation of others parts of the commonwealth. These measures effected not only a complete reversion to a system of local naturalization, but also a complete recasting of the earlier law as to the acquisition of British nationality by birth. Under these enactments the status of a British subject (or commonwealth citizen) entails the citizenship of at least one part of the commonwealth; *e.g.*, citizenship of the United Kingdom and colonies, Canadian citizenship, Australian citizenship, etc. A person may possess more than one such local citizenship; *e.g.*, a person born in Australia of a father born in the United Kingdom has both Australian and United Kingdom citizenship. In the law of the United Kingdom and colonies, a person who is a British subject by virtue of his possession of citizenship of another part of the commonwealth and who is also a citizen of Ireland is entitled to local citizenship as of right if he has been ordinarily resident locally for 12 months or for such shorter period as may be accepted in his particular case, or if he is in crown service under the local government. The possibility of an individual's availing himself of this right is, however, considerably lessened by the provisions of the Commonwealth Immigrants act, 1962, which may exclude him from acquiring the necessary residential qualification. Acquisition of citizenship of the United Kingdom and colonies, moreover, may, and usually does, involve automatic forfeiture of citizenship of another commonwealth country. The other countries of the commonwealth are not in any event so liberal toward applicants for citizenship; they ordinarily accord to persons who are already British subjects or Irish citizens at most a species of preferential treatment in the matter of naturalization. In nearly all of them, however, the process whereby a citizen of another such country or of the Republic of Ireland is admitted to citizenship is now officially termed registration rather than naturalization (the same terms apply to a woman who has married a local citizen and to a minor child).

Despite the changes described, the general statutory conditions for the naturalization of aliens in the United Kingdom, which apply uniformly in the colonies and in certain protectorates, have not altered materially since 1870. An applicant must be of full age and must have resided in the place of application or have been in crown service under the appropriate government, or partly the one and partly the other, for 12 months immediately preceding his application. He must adduce further periods of residence or service amounting to an aggregate of 4 years falling within the 7 years preceding this period of 12 months. The secretary of state has, however, certain discretion to vary the periods and types of residence or service normally required. The applicant must in addition be of good character, must have a sufficient knowledge of English and must intend to reside in the United Kingdom or colony, or to enter or to continue in crown service, service of an international organization of which the United Kingdom is a member, service of a person or body established in the United Kingdom, etc. A British-protected person (*i.e.*, a person belonging to a protectorate, protected state or trust territory under United Kingdom administration) is still technically an alien, although exempt from the alien restriction acts and thus entitled as of right to land or to reside in the United Kingdom subject to the provisions of the Commonwealth Immigrants act. Such a person is eligible for naturalization upon the same terms as any other alien except that he need only have been ordinarily resident for 12 months, or for such shorter period as may in a particular case be accepted, immediately preceding his application, or be actually in crown service.

The grant or refusal of any application for naturalization, or of citizenship registration by or on behalf of a minor still remains a matter of complete discretion, as it does for those of age (see above). A minor who is adopted by a male citizen of the United Kingdom and colonies, however, acquires the status of his adoptive parent automatically. A woman married to a citizen of the United Kingdom and colonies, whether she be an alien or already a British subject or Irish citizen, neither acquires the status of her husband automatically nor is eligible therefor by naturalization, but is entitled to obtain it by registration as of right without satisfying any condition as to residence.

A citizen of the United Kingdom and colonies by naturalization, while he remains such, possesses exactly the same status as a person who becomes a citizen by any other means (*i.e.*, by birth, descent, incorporation of territory, registration or adoption). But he may be deprived of it if: (1) his certificate was obtained by fraud, etc.; (2) he has shown himself by act or speech disloyal or disaffected toward the sovereign; (3) he has been guilty of trading with an enemy during war; (4) he has within 5 years of his naturalization been sentenced to imprisonment for upward of 12 months; (5) he has been ordinarily resident abroad for a continu-

ous period of 7 years including neither crown service nor service of an international organization of which the United Kingdom is a member and has failed to register annually at a British consulate. Where the ground of deprivation is other than the last, the deprivation either may or must be preceded by a quasi-judicial inquiry. A citizen by registration may be deprived of his status only if he has obtained registration by fraud, etc., or if, having acquired citizenship of another country of the commonwealth by naturalization, he has been deprived thereof upon grounds similar to those laid down for deprivation of naturalization in the United Kingdom and colonies.

Other Countries of the Commonwealth.—Although in a sense the British Nationality act of 1948 is the agreed model for legislation elsewhere, the requirements for naturalization and registration laid down by other commonwealth countries sometimes depart considerably from those of the parent act. The apparent conditions are moreover most misleading unless read in the light of the immigration laws, the effect of which may well be to exclude some categories of applicants altogether. It has also to be borne in mind that the voluntary acquisition (otherwise than by marriage) of citizenship of any country outside the commonwealth (and often of any country whatsoever) is a ground for the discretionary, if not the automatic, deprivation of citizenship of every country of the commonwealth overseas, irrespective of the means of acquisition of such citizenship. Further, intolerance of multiple status goes so far in some commonwealth countries that local citizenship may be withdrawn from a person who merely retains a previous citizenship rather than acquires a new one.

Canada.—The process of acquisition of citizenship otherwise than by birth, applicable to British subjects, Irish citizens and aliens alike, is by discretionary grant of a certificate. An applicant must be of full age or be the resident spouse of a Canadian citizen. An applicant other than the wife of a Canadian citizen, or a minor child, must have acquired Canadian domicile; *i.e.*, must have resided for five years after lawful admission for permanent residence. A certificate of citizenship may be revoked (1) for evasion of trial for an offense against the state; (2) for obtaining the certificate by fraud, etc.; (3) for disloyalty or disaffection; (4) where the holder has been ordinarily resident abroad for six years (or in any foreign country of which he was formerly a national for two years) without maintaining substantial connection with Canada.

Australia.—An alien applicant for Australian citizenship by naturalization must file a preliminary application or "first papers," as was formerly required under the law of the United States, and must show that he has an adequate knowledge of the responsibilities of citizenship. The remaining requirements imposed on him are substantially the same as those laid down in the law of the United Kingdom and colonies. Although a British subject or an Irish citizen acquires Australian citizenship by registration rather than by naturalization, the process is still discretionary and the conditions therefor are exactly the same as those for the naturalization of aliens, except that the requirement of "first papers" is waived and that the residence requirement may be reduced to a period of one year. The spouse of an Australian citizen or a minor child may be granted a certificate of registration at discretion without any residential or other qualification.

New Zealand.—In New Zealand the law governing the acquisition of citizenship by registration and naturalization and the loss of citizenship so acquired is virtually identical with that of the United Kingdom and colonies except that an alien woman other than a British-protected person married to a New Zealand citizen can acquire citizenship by registration only at discretion, and that "first papers" and an adequate knowledge of the responsibilities of citizenship are required of an applicant for naturalization.

Ceylon.—Naturalization as such is unknown in the law of Ceylon. Citizenship by registration is available as of right to certain categories of persons of Ceylonese descent and at discretion to spouses of citizens who shall have been resident one year. These cases apart, not more than 25 certificates of registration may be granted in any one year, and these only to persons rendering eminent public services or naturalized in Ceylon before its achievement of independence. Special provision has been made, however, for the admission to citizenship of resident Indians and Pakistanis.

India and Pakistan.—Aliens may be naturalized after five years' residence but generally only if they be citizens of countries which permit the naturalization of Indians or Pakistanis. What degree of preferential treatment in obtaining citizenship by registration is accorded to British subjects other than persons of local descent, or wives or minor children of citizens, was obscure in the 1960s.

Ghana.—An alien other than a British-protected person may be naturalized at discretion in Ghana if he has been resident six years. A British subject or British-protected person may similarly become a citizen by registration upon residence for five years or for such shorter period as may be accepted.

Malaysia.—Discretionary naturalization is the ordinary means of acquiring citizenship of Malaysia by aliens, British subjects and Irish citizens. Citizenship by registration is available, normally as of right, to wives and resident children of citizens. An aggregate of ten years' residence is ordinarily required as a condition of naturalization. But persons who have served in the armed forces for specified periods are entitled to naturalization as of right without any condition as to residence.

Before Malaysia became an independent federation in 1963, citizenship by registration was available in Singapore virtually as of right to persons born in the Federation of Malaya, citizens of the United Kingdom and colonies and, at least potentially, to citizens of any other country of the commonwealth or of the Republic of Ireland. The residence qualification in this connection was two years. Minor children and women married to citizens were admissible to citizenship by registration at discretion. Naturalization was available at discretion to aliens resident for an aggregate of eight years.

Others.—The naturalization laws of countries such as Uganda, Cyprus and Malta did not differ materially from the general pattern, but there was considerable variation in detail among them; by the mid-1960s they had not achieved their permanent form.

(C. Py.)

OTHER COUNTRIES

Since it is for each state to determine under its own law who are its nationals, a great variety of solutions can be found in the laws concerning nationality and naturalization enacted by the various countries of the world. Such legislation is recognized by other states, insofar as it is consistent with international conventions, international custom and the principles of law generally recognized with regard to nationality (*cf., Hague Convention on Double Nationality*, art. 1; April 12, 1930).

Normal and exceptional grounds are often provided side by side. In normal cases a certain period of residence, which varies from 2 to 15 years, intention to reside permanently, a minimum age, capacity to act according to the law of the state of the former nationality or of the state applied to or of both, good character, physical and mental health, a sufficient command of the language of the prospective adopting country and the ability to earn a livelihood or to support himself are the usual requirements, coupled with evidence that, upon naturalization, the applicant will lose his former nationality or has taken steps to renounce it.

Preferential treatment, consisting in the reduction or waiver of the residential qualification, is frequently accorded to husbands or to wives of nationals and to their children, if they do not acquire the nationality of the head of the family automatically or by way of option, and to ethnically related groups. Previous possession of the nationality of the naturalizing country is in some instances an advantageous and in others a precluding factor. Underdeveloped countries facilitate the naturalization of skilled persons, including teachers, and of those who contribute to the establishment of industry or invest in land. Some countries, which do not regard birth within the jurisdiction as a ground for the acquisition of citizenship at birth, permit persons born within the jurisdiction to assume local nationality unconditionally or be subject to less stringent conditions.

Government service at home or abroad, or service with the armed forces, is in some countries a ground for automatic or pre-

ferred naturalization. Distinguished services rendered to the state may be regarded as a reason for waiving all the usual requirements, but in these circumstances the power to naturalize appears to be mostly reserved for the legislature, except in countries where the head of state exercises very wide powers. While the power to grant naturalization rests with the legislature in a small number of countries, it is usually vested in the executive. However, in countries influenced by the practice in force in the United States, it is a function entrusted to the judiciary. In some countries two procedures exist, depending upon the grounds for and the effects of the naturalization in question. Revocation of naturalization is almost uniformly provided for, if the grant was obtained by fraud or if the grantee resides abroad for a prolonged period without special authorization.

According to international law naturalization must be, and is, with few exceptions, the result of a voluntary act, which may be express or implied, on the part of the person seeking a new nationality. In face of the great diversity of provisions which permit the grant of local nationality to an alien, it must not be overlooked that, following the decision of the International Court of Justice in the Nottebohm case, a state may not be able to assert its right of protection on behalf of a naturalized subject unless a genuine link existed between the naturalizing state and the new citizen at the time when naturalization was granted.

NATURAL LAW, or LAW OF NATURE, a term used, not always in the same sense, to denote a system of right or justice held to be common to all mankind and so independent of positive law. The use of the term in the natural sciences (physics, etc.) to mean the statement of predictable relationships among and between phenomena is wholly distinct.

The article JURISPRUDENCE deals with natural law in juristic philosophy; and the article ETHICS, HISTORY OF, deals with ideas of nature and of right in connection with ideas of good and of the moral conscience. Here it may be useful to remark some points of difference between thinkers on the subject as they arise from different approaches to "nature."

Aristotle held that what was "just by nature" was not always the same as what was "just by law"; that there was a natural justice valid everywhere with the same force and "not existing by people's thinking this or that"; and that appeal could be made to it from the positive law. He drew his instances of the natural law, however, chiefly from his observation of the Greeks in their city states, with their subordination of women to men, of slaves to citizens and of barbarians to Hellenes. The Stoics (*q.v.*), on the other hand, conceived an entirely egalitarian law of nature in conformity with the "right reason," or *logos,* inherent in the human mind; and Cicero wrote of a "true law, right reason, diffused in all men, constant and everlasting." The Roman jurists paid lip service to this notion, and St. Paul seems to reflect it when he writes of a law "written in the hearts" of the Gentiles (Rom. ii, 14–15).

St. Augustine of Hippo took up the Pauline mention and developed the idea of a man's having lived freely under the natural law before his fall and his subsequent bondage under sin and the positive law. Gratian in the 11th century simply equated the natural law with the divine law, that is, with the revealed law of the Old and the New Testament, in particular the Christian version of the Golden Rule (*q.v.*).

St. Thomas Aquinas (*q.v.*) propounded an influential systematization. The eternal law of the divine reason, he maintained, though it is unknowable to us in its perfection as it is in God's mind, is yet known to us in part not only by revelation but also by the operations of our reason; and the law of nature, which is "nothing else than the participation of the eternal law in the rational creature," comprises those precepts that mankind is thus able to formulate, namely, the preservation of one's own good, the fulfillment of "those inclinations which nature has taught to all animals" and the pursuit of the knowledge of God. Human law must be the particular application of the natural law.

Other scholastic philosophers, for instance John Duns Scotus, William Ockham and, especially, Francisco Suárez, emphasized the divine will instead of the divine reason as the source of law. This "voluntarism" influenced the Catholic jurisprudence of the Counter-Reformation, but the Thomistic doctrine was later revived and reinforced to become the main philosophical ground for the papal exposition of natural right in the social teaching of Leo XIII (*q.v.*) and his successors.

The epoch-making appeal of Hugo Grotius (*q.v.*) to the natural law belongs to the history of jurisprudence; but whereas his fellow-Calvinist Johannes Althusius (1557–1638) had proceeded from theological doctrines of predestination to elaborate his theory of a law binding on all peoples, Grotius insisted on the validity of the natural law "even if we were to suppose . . . that God does not exist or is not concerned with human affairs." A few years later Thomas Hobbes (*q.v.*) was arguing, not from the "state of innocence" in which man had lived in the biblical Eden, but from a savage "state of nature" in which men, free and equal in rights, were each one at solitary war with every other. After discerning the right of nature (*jus naturale*) to be "the liberty each man hath to use his own power for the preservation of his own nature, that is to say, of life," Hobbes defines a law of nature (*lex naturalis*) as "a precept of general rule found out by reason, by which a man is forbidden to do that which is destructive of his life . . ." and then enumerates the elementary rules on which peace and society can be established. Grotius and Hobbes thus stand together at the head of that "school of natural law" which, in accordance with the tendencies of the Enlightenment, tried to construct a whole edifice of law by rational deduction from a fictitious "state of nature" followed by a social contract (*q.v.*). In England, John Locke (*q.v.*) departed from Hobbesian pessimism to the extent of describing the state of nature as a state of society, with free and equal men already observing the natural law. In France, where Montesquieu had argued that natural laws were presocial and were superior to those of religion and of the state, J. J. Rousseau (*q.v.*) postulated a savage virtuous in isolation and actuated by two principles "prior to reason," self-preservation and compassion (innate repugnance against the sufferings of others).

The Declaration of Independence of the United States refers only briefly to "the Laws of Nature" before citing equality and other "unalienable" rights as "self-evident." The French Declaration of the Rights of Man and of the Citizen asserts liberty, property, security and resistance to oppression as "imprescriptible natural rights." The philosophy of Immanuel Kant (*q.v.*) renounced the attempt to know nature as it really is, yet allowed the practical or moral reason to deduce a valid system of right with its own purely formal framework; and Kantian formalism contributed to the 20th-century revival of naturalistic jurisprudence.

On the level of international politics in the 20th century the

assertion of human rights (*q.v.*) was the product rather of an empirical search for common values than of any explicit doctrine about a natural law.

NATURAL LAW, in science, means the formulation of some uniform character, mode of behaviour or uniform correlation of things or events; and it is frequently used in describing uniform relationships among various phenomena. Any such uniformity may be called a natural law; *e.g.*, all the laws formulated in physics and chemistry. On the other hand the term law of nature is sometimes restricted to irreducible or primary laws (like the law of gravitation) as distinguished from derivative laws (like Johannes Kepler's laws of planetary motion). *See* SCIENTIFIC METHOD.

NATURAL PRODUCTS, TOTAL SYNTHESIS OF. Natural products include all chemical substances produced by living plants and animals. Examples of classes of natural products include fats, proteins, carbohydrates, vitamins, alkaloids, antibiotics, steroids, terpenes, essential oils and many others. Total synthesis, rigidly defined, means the synthesis of a chemical substance from the elements of which it is composed. Since many relatively simple substances have already been made from the elements, in practice a total synthesis means synthesis from these substances rather than from the elements themselves.

The original objective of the science of organic chemistry was to elucidate the structures of, and to totally synthesize, all known natural products. Before such an ambitious objective could be realized, however, it was necessary to develop a logical and systematic science of organic chemistry. (*See* CHEMISTRY: *Organic Chemistry*). This development occupied the attention of numerous chemists over a period of about 200 years. Although many notable successes in total synthesis were achieved relatively early in the history of organic chemistry, only in the mid-20th century was sufficient knowledge accumulated to permit organic chemists to turn vigorously and successfully toward their original objective.

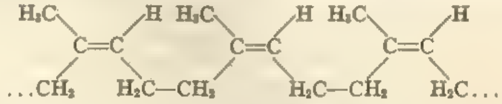
Perhaps the first total synthesis of an organic substance was the synthesis by F. Wöhler in 1828 of urea, a nitrogenous waste product formed in the kidneys of animals. Wöhler found that urea was formed simply by heating an aqueous solution of ammonium cyanate:

$$NH_4 \cdot O \cdot CN \rightarrow H_2N \cdot CO \cdot NH_2$$

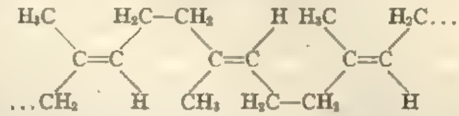
Since ammonium cyanate was a well-known inorganic substance and could be made from the elements carbon, nitrogen, oxygen and hydrogen, this reaction constituted a total synthesis. This first synthesis of a typical organic substance from purely inorganic starting material contributed toward abandonment of the idea of a "vital force" associated with the formation of organic matter, and organic chemistry was free to develop as a logical, orderly science utilizing concepts that had been formulated much earlier in the study of inorganic chemistry.

Total synthesis of organic substances is taken by the organic chemist as final and conclusive proof for the correctness of a structure arrived at by degradative or other methods. Sometimes this conclusive structure proof is the motivation for total synthesis. Frequently, however, total synthesis has important economic significance. As an example, the cultivation of the plant from which the blue dye indigo may be prepared was once an important agricultural industry. In 1883 A. von Baeyer elucidated the structure of indigo as the result of experiments extending over 18 years and devised two syntheses for the substance. In 1890 K. Heumann devised a commercially practical synthesis of indigo, permitting the sale of the synthetic product at a price lower than that of the natural dye. The synthetic product soon controlled the market. A quite different case is that of the total synthesis of the natural drug quinine by R. Woodward and W. Doering in 1945. Although a brilliant chemical achievement, the synthesis has not been applied commercially. Other synthetic drugs such as Atabrine (Atebrin) adequately control malaria, and are much easier to produce.

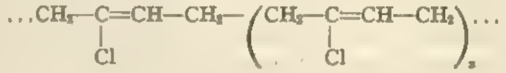
It is to be emphasized that a total synthesis leads to a material that is chemically identical in all respects to the natural product; the synthetic product is not a substitute or artificial. The field of the rubbers affords a good example of this distinction. Natural rubber is a polymer (*see* POLYMERIZATION) of isoprene (2-methyl-1,3-butadiene) in which all of the isoprene units are arranged in the cis manner; *i.e.*, similar groups are arranged on the same side of the molecule. The arrangement is as follows:



The alternative all trans arrangement of the isoprene units represents the structure of gutta-percha:

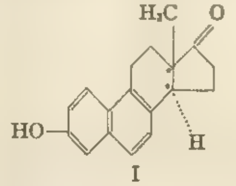


During the World War II period, when supplies of natural rubber were cut off from the western Allies, many synthetic rubbers were developed and used. All of these were substitute rubbers having some of the desirable properties of natural rubber but only grossly approximating its chemical structure. One of the first synthetic rubbers widely used in the United States was neoprene, a polymer of 2-chloro-1,3-butadiene:

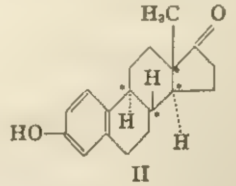


Neoprene has a random cis-trans arrangement of the 2-chloro-1, 3-butadiene units. It was not until later that a synthesis of natural rubber was achieved. In 1954 Goodrich-Gulf Chemicals, Inc., announced the synthesis of a rubber identical with natural rubber (referred to as "synthetic natural rubber"). In 1955 the Firestone Tire and Rubber company announced a similar product, and in 1956 the Phillips Petroleum company announced the synthesis of both cis and trans polyisoprene in pure form. These syntheses were achieved by polymerizing isoprene by means of certain stereospecific catalysts, perhaps a trialkylaluminum complexed with titanium tetrachloride.

The attainment of stereospecificity was one of the principal problems to be conquered in the total synthesis of natural products. In the case of the rubbers, the problem was production of a cis rather than a trans arrangement of the isoprene units. An even more subtle type of isomerism is involved in the structures of many natural products, so-called optical or dextro-levo (d, l) isomerism (*see* STEREOCHEMISTRY). This isomerism is dependent upon the fact that a molecule containing an asymmetric carbon atom (one which is attached to four entirely different groups) can exist in two arrangements in three-dimensional space. The two possible arrangements are mirror images of each other; *i.e.*, bearing the relationship of a right to a left hand. A given natural product represents only one of the various possible geometrical arrangements. Thus, the natural estrogenic hormone equilenin (I) contains two different asymmetric carbon atoms (denoted by the asterisks) and is capable of existence as four (*i.e.*, 2^2) isomers; these are *d*- and *l*-equilenin and *d*- and *l*-isoequilenin. The first total synthesis of a steroid was the W. Bachmann, W. H. Cole and A. Wilds synthesis of equilenin in 1939. All four of the possible stereoisomers were obtained.



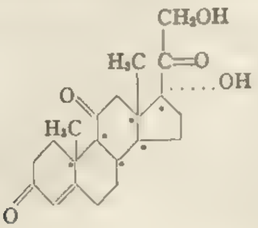
I



II

The estrogenic hormone estrone (II) represents a more difficult synthesis problem. Since there are four different asymmetric carbon atoms present, this structure can exist as 16 (*i.e.*, 2^4) possible stereoisomers. Largely because of the efforts of G. Anner and K.

Miescher in 1948 and by W. Johnson later, all of the stereoisomers of estrone were synthesized. Only one of these, of course, is the natural product. Considerable interest centred around the steroid cortisone (III), which is able to relieve the



III

symptoms of rheumatoid arthritis and is beneficial in the treatment of various allergies. A partial synthesis of this steroid from other naturally occurring steroids is carried out commercially. Total syntheses were devised by Woodward in 1951 and later by L. Sarett and by L. Barkley.

The examples cited above point up some of the problems encountered in total synthesis and indicate the extremely rapid progress being made. The following listing of a few notable total syntheses further indicates something of the scope of the field: camphor (G. Komppa, 1903); cocaine (R. Willstätter, 1923); riboflavin or vitamin B_2 (R. Kuhn, P. Karrer, 1935); thiamine or vitamin B_1 (R. Williams, 1936); vitamin A (O. Isler, 1947); carotene (Karrer, H. Inhoffen, 1950–51); morphine (M. Gates, 1952); sucrose or cane sugar (R. Lemieux, 1953); oxytocin, a peptide hormone (V. du Vigneaud, 1953); strychnine (Woodward, 1954); reserpine, a *Rauwolfia* alkaloid (Woodward, 1956); penicillin V (J. Sheehan, 1957); chlorophyll (Woodward, 1960); insulin (Y. C. Du, 1966).

NATURAL RESOURCES. The materials of the environment useful to man are resources. Any of the many substances of the earth, the oceans and the air may become invested with an economic interest and thereby become resources. For anything to be sufficiently useful to be a resource it must satisfy three fundamental conditions: (1) it must satisfy a need of man without alteration, as water does, or it must be easily adaptable to his needs; (2) man must have developed his skills sufficiently so that he can utilize the resources available to him; and (3) the resource must be readily available with a reasonable expenditure of energy or other resources. A material may be economically useless one day and become a valuable resource the next.

Resources are either human or physical; and physical resources are either natural or manufactured. This article is concerned with natural resources which are commonly classified as vegetable, animal or mineral but these three categories may be extended to include energy from the sun, the soils of the earth and water. Resources may be further classified as nonrenewable (*e.g.*, minerals) or renewable (vegetation and water). The nonrenewable resources may be regarded as fund resources which are diminished by use. This is particularly the situation in the case of the fuel minerals. Many of the metals are not destroyed and varying fractions, depending upon the metal, can be recovered and reused. The renewable resources may be termed flow resources for the reason that with careful use they may last indefinitely. For example, a forest, managed on a sustained-yield basis, can produce timber and other forest products year after year without depleting the resource.

The adequacy of the earth's resources to sustain a growing population at different levels of culture is subject to debate, depending in part on the outlook of the inquirer. The more optimistic observer looks to technology to satisfy man's increasing demands. Great dams can be built to impound water; crop yields may be increased by plant breeding, fertilization, irrigation and mechanization. By geophysical methods mineral resources may be located and by improved methods of recovery, beneficiation and processing greater quantities of minerals may become available. The more pessimistic investigator observes the destructiveness of wars and the unproductive use of a rich heritage. He notes the impoverishment of the soil, the evidences of accelerated erosion, the destructiveness of great floods and the rapid use of fund resources.

It is obvious that wastefulness and the capacity to conserve resources, especially nonrenewable resources, exist simultaneously and a people would be without hope if they did not believe in the ability of man to satisfy his needs for an indefinite future.

Aside from economic motives, there may be humane or historic reasons for conservation of natural resources (*see* National Parks and Nature Reserves; Wildlife Conservation).

This article is divided into the following sections representing the main categories of natural resources:

I. Soils
II. Vegetation
III. Animal Life
IV. Water
V. Minerals
VI. Strategic Resources
VII. Climate

The natural resources of the continents and nations are discussed more specifically in the articles on those areas.

I. SOILS

The soil is one of the most fundamental resources of the world. The countries that have large areas of arable land are most fortunate. The food-producing capacity of the land, if protected against destructive erosion and depletion of the plant nutrients, can be maintained indefinitely. To the extent that the fertility is maintained without impairment, soil may be regarded as a flow resource.

The soils of the world were formed under a variety of conditions. The parent material from which the soil is derived is acted upon by a number of physical and chemical processes. The properties of the soil reflect something of the climate, the slope of the land, drainage conditions and the stage of development the soil has attained, but the parent material imparts distinctive characteristics to the soil which other factors cannot destroy or alter substantially.

A sandy soil derived from a sand-yielding formation remains a sandy soil although climatic conditions may impart to it distinctive structural characteristics. Abundant precipitation may result in excessive leaching but limited rainfall may permit the retention of plant nutrients in sufficient quantities to guarantee high productivity over a long period of time. Plants and animals and especially the microorganisms in the soil, assist in the formation of the soil and contribute humus (*q.v.*), which serves a number of useful purposes such as the retention of moisture and the maintenance of cultivability.

Soils may be classified into zonal soils, intrazonal soils and azonal soils. These major groups of soils may be further classified into families, series and types. The well-developed or mature zonal soils are strongly identified with the climatic and vegetational conditions under which they have developed. The intrazonal soils show less distinctively the influence of climate and vegetation and show more certainly their relation to other factors such as slope or drainage. The azonal soils, such as recent alluvium and slightly altered parent material, have not advanced sufficiently in development to take on the physical and structural characteristics of the mature soils.

Within the tropics where rainfall is abundant and the temperatures are uniformly high, the tropical forest is the typical vegetational cover. Under these conditions the mature zonal soils are generally low in plant nutrients because of excessive leaching, high in the oxides of iron and aluminum, and under cultivation deteriorate rapidly. These soils are commonly brick red in colour and contain beneath the surface a claylike substance known as laterite (*q.v.*). The mature soils in tropical America, central Africa, Indonesia and southeastern Asia, developed under humid

tropical conditions, are known as latasols and require careful management to maintain their fertility once the original forest has been removed and the land brought under cultivation.

On the savannas and the steppes of the tropics the soils are not so seriously leached as in the humid tropics but laterization is an important feature of the soil-forming processes. The leaching process is interrupted during the dry season and the maturing of the grasses helps to maintain the fertility of the soil. The mineral nutrients that the grasses have brought up from the lower horizons are made available in the surface layer when the grasses die and decay or are burned. The soils of these extensive grasslands, to the extent that they have been brought under cultivation or will be transformed from natural savannas into cultivated fields, constitute a resource of major dimensions. When the world needs the food and industrial raw materials these fertile soils can produce, cultivation can be greatly expanded.

Extensive areas in the humid subtropics such as southeastern United States, southern China, southern Brazil and southeastern Australia have soils that have developed under a forest cover. The soils in these areas are commonly red or yellow and display some of the characteristics of soils of the tropics. They show also the results of podsolization, a process identified with soil formation in the northern latitudes. These are not everywhere rich in plant nutrients because of excessive leaching, but with proper land management and fertilization these soil areas can produce great quantities of corn, cotton, tobacco, peanuts and vegetables. If they are neglected, their erodibility may result in rapid deterioration. To preserve and maintain the land in a high state of productivity will require vigilance and an understanding of the needs of the land.

Over a broad area across central Canada from the Rocky mountains to the Atlantic and across Eurasia from Scandinavia to the Pacific, the soils developed under the northern softwood forest or taiga are classed as podsols. These light gray or ashen-coloured soils are the result of the decomposition of organic matter which charges the downward-moving waters with acids which help to remove in solution the iron compounds which otherwise would give the soil a reddish colour. Beneath the thin layer of leaf litter the topsoil or A horizon of the podsols is distinctly light coloured and generally infertile. The downward percolating waters transfer the humus, clay and other fine materials downward into the subsoil. The topsoil becomes a white bleached layer directly beneath the forest litter. The subsoil is compact and coffee brown in colour. In the glaciated parts of northeastern North America and northwestern Europe are extensive areas of true podsols, which because of their sandy character, natural acidity and poor drainage have limited usefulness. Land just cleared is deceptively dark in colour because of the thin layer of leaf litter, but after being cultivated for a few years the organic matter decays and an infertile layer of ashen-gray inorganic matter is all that remains. These acidic podsols are not well suited for agriculture though potatoes, rye, oats, certain meadow grasses and vegetables do well. Large areas probably should remain in forest and be used for the production of timber and other wood products.

In northeastern United States, in much of west central Europe and in northern China the soils, developed under the deciduous forest, are mainly podsolic in character. These soils are grayish-brown in colour and have inherent structural characteristics that give them an enduring quality. The humus content is greater than in the podsol soils but they require care to maintain their high productivity.

The eternally rich lands of the world are those that have developed under a cover of grass in the intermediate latitudes. The soils in these great grasslands originated and evolved in areas of moderate to scant rainfall. In the tall-grass prairie there has been sufficient precipitation over a long period of time to remove the calcium salts and other easily dissolved minerals. The soils developed under these conditions are deep and fertile though they may require the application of lime. Nowhere in the world are the black prairie soils so well developed as in the corn belt of the United States.

In the grassland areas that receive a smaller amount of precipitation, the calcium salts and other minerals are retained and the soil may be described as slightly alkaline. These soils are known as chernozems (black earth). They are widely distributed in the dry plains of the United States and Canada, the Soviet Union, Manchuria, India, the Argentine pampas, Uruguay and eastern Australia. Where the surface of the land is relatively flat or gently undulating the danger of water erosion is slight. Under cultivation the chernozems and other soils rich in organic material suffer from wind erosion if not protected by wind stripping, mulch tillage (stubble mulching) or by the use of cover crops.

On the dry margins of the chernozems lie extensive areas that are best described as steppes. In these areas the soils have developed under subhumid conditions. These dark-coloured soils are not as rich in organic matter as the chernozems and the prairie soils. In favourable years these dry lands may be brought under cultivation and used for the production of the drought-tolerant grains such as wheat and barley. The steppes are well suited to grazing and most areas should be left in grass and used to support a pastoral industry. The soil resources of the steppes can be used most effectively if only limited areas are brought under cultivation.

In the deserts of the world small areas of fertile soils can be irrigated and brought under cultivation. The soils developed under low-rainfall conditions are potentially productive where sufficient water is available. These irrigable lands usually have soils that are rich in mineral nutrients but are generally low in organic matter and nitrogen.

The full use of the soil resources of the world to meet the needs of an increasing population for more food, fibres and other industrial raw materials will require the clearing of virgin lands, the drainage of marshlands, the irrigation of larger areas of desert and semiarid lands, the use of fertilizers and the development of more productive plants and animals. Extensive areas must be protected from destructive erosion and depletion if their productivity is to be maintained and enhanced for an indefinite future.

See SOIL; AGRICULTURE; FERTILIZERS AND MANURES; IRRIGATION; LAND RECLAMATION.

II. VEGETATION

A very high proportion of the earth, in spite of great irregularities in terrain, high altitude, expansive ice-covered areas in Antarctica, Greenland and the high mountain areas, and the extensive wastelands of the deserts, is mantled by vegetation either natural or cultivated. The natural or original vegetation of the earth may be classed as grasslands, grass and shrubs of the steppes and deserts, and forest. The plant communities may differ greatly over the world, particularly in respect to floristic composition, but the assemblage of plants makes it possible to identify the major vegetation zones of the earth. The forest of equatorial Africa is very different from the spruce forest of Canada but both are forests. Similarly, the component grasses of the campos of Brazil may be quite unlike the plants that make up the assemblage of grasses in the Nebraska prairie but both are grasslands. Also the scant grasses and shrubs of the desert margin of the Sudan produce a steppe area not unlike the great steppes that border upon the desert of Soviet Central Asia.

The science concerned with plant communities and the environmental, biological and physical factors that affect composition and succession is known as plant ecology (*see* ECOLOGY: *Plant Ecology*).

Grasslands.—Approximately 13,000,000 sq.mi. or 24% of the land area of the earth can be classed as grassland. The great grasslands consist of (1) tall-grass savanna, 31%; (2) high-grass savanna, 22%; (3) desert-grass savanna, 18%; (4) tall-grass prairie, 13%; (5) short-grass steppe, 10%; and (6) mountain grassland, 6% of the total.

The savanna grasslands cover extensive areas between the equatorial forests and the trade-wind deserts and lie largely within the tropics. The rainfall ranges from 30 to 80 in. annually with the maximum strongly concentrated in the summer or high-sun

period. It is this marked seasonality of the precipitation that has favoured the development of the tall luxuriant grasses that make up the savanna. Where the savanna borders upon the equatorial forest the expanse of grass may be interrupted by clumps or islands of trees or by a gallery forest along the watercourses or in low areas where water is available in all seasons. Toward the desert margin of the savanna the grasses are shorter and less abundant and drought-resistant shrubs become a part of the assemblage of species in the plant communities.

The tropical savannas are well represented in South America in the llanos of the Orinoco basin, the campos of Brazil and the Gran Chaco of northern Argentina and Paraguay. In Africa the Sudan is largely an expansive grassland extending from the Atlantic to the highland of Ethiopia along the parallel of latitude 10° N. This grassland extends southeastward onto the highland of east Africa. Also south of the equatorial forest an area of savanna lies across northern Angola and the southern portion of the Republic of the Congo. In northern and northeastern Australia, savanna covers an important fraction of the continent.

These extensive grasslands of the tropics, in spite of hot humid summers and the dry season in the winter or low-sun period, are widely used for cattle grazing. Locally the grassland has been brought under the plow and cultivated crops such as cotton, peanuts, sorghum grains and vegetables are grown. Potentially large areas in the tropical savannas can be cultivated and when the world requires larger quantities of the crops that can be produced there, greater use will be made of these fertile and productive lands.

The tall-grass prairies originally included the immense prairies of midland North America, the pampas of South America, the rich prairies of eastern Europe such as the Hungarian basin, the Rumanian plain and the extensive grasslands of the Soviet Union north of the Black sea and extending eastward between the northern forest and the desert interior of Asia. Limited areas of prairie once made up the vegetational cover of the veld in South Africa, the upland of Madagascar, the plains of southeastern Australia and the eastern half of South Island in New Zealand.

The tall-grass prairie of the mid-latitudes was the natural habitat of a great variety of grazing animals such as the buffalo in North America. Because of the high fertility of the soil developed under the prairie vegetation and an annual precipitation of 15 to 40 in., a high proportion of the mid-latitude prairie has been brought under cultivation. In many areas in the corn belt of North America the original grasses, including bluejoint (blue stem), needle grass and wheat grass, have all but disappeared. Only along fence rows and in a few relict areas have the original plant communities been preserved. These immense grasslands are now the great granaries of the world where much of the world's corn, wheat, rye, flax, oats, barley, soybeans and sorghum grains are grown. Also, the cultivated grasses and feed grains that have replaced the native grasses support a livestock industry of major proportions.

Grasses and Shrubs of the Steppes and Deserts.—Short scant grasses and intermingled shrubs border the desert areas both in the tropics and in the intermediate latitudes. With the mountain grasslands these areas cover approximately 32% of the land area of the world. The component grasses of these steppelands include grama, buffalo grass and needle grass. In drier parts of the steppe open spacing of the clumps of grass and herbaceous plants is a characteristic feature. These great realms of scant grass supported a pastoral civilization in the old world, and briefly a range industry in the new. In the more fertile parts of the steppe and where the annual precipitation exceeds 12 in., dry farming may be practised. The crops grown must be drought resistant such as wheat, barley, millet and the sorghum grains.

Other areas commonly included among the grasslands are the diminutive patches of grass and herbaceous plants that give greenness to desert areas after each rain or brief rainy season. In the high latitudes the tundra, and in high altitudes, the alpine meadows present some of the aspects of grassland. To a limited extent they are used for grazing and support an animal population of reindeer, musk oxen and a variety of fur-bearing animals. (*See* Grassland; Grasses.)

Forests.—The natural forest areas of the world cover approximately 22,000,000 sq.mi. or 42% of the earth's surface. The forests may be classified into a number of major types related chiefly to the nature of the assemblage of trees and the geographic location of the forest.

Tropical Rain Forest.—This is luxuriant, evergreen forest consisting of trees of unequal size and height and of varying ages forming a dense canopy of thick, leathery leaves, and composed of a variety of trees such as legumes, laurels, myrtles, figs, satinwood, mahogany and rubber trees, a true climax forest with an intermingling of many species. This type of forest thrives in areas within the tropics where temperatures are uniformly high and where the annual precipitation amounts to 60 to 200 in. In the equatorial areas of South America, Africa and Indonesia and the windward coasts within the tropics the temperature and moisture conditions support the true tropical rain forest.

Light rain forest consists of a variety of conifers and deciduous trees in the lower middle latitudes and extending into the tropics. It occupies extensive areas in southeastern United States, eastern Brazil, southeastern Asia, parts of east Africa and northern Australia. Temperatures are not as high in these areas as in the equatorial lowlands. The rainfall is also somewhat lower, averaging from 40 to 80 in. annually. As a consequence these humid subtropical areas originally were mantled by a light but valuable forest.

Deciduous forest consists of broadleaf trees which drop their leaves chiefly in the autumn and come into leaf again each spring. Typical trees include the oak, birch, beech, maple, ash and hickory. The dominant trees differ from place to place depending in part on drainage. The beech-maple association may be dominant in the wetter areas whereas the oak-hickory association may be characteristic of the higher, well-drained regions. The original deciduous forest was best developed in eastern United States, western and central Europe and eastern China. The total area of approximately 6,500,000 sq.mi. covered 12% of the land area of the earth.

Coniferous Forest.—Characteristic of middle and higher latitudes, this type of forest is made up of uniform stands of similar or related evergreen trees such as pine, fir and spruce. In the northern hemisphere it is commonly known as the northern softwood forest. In Eurasia from Scandinavia to the Sea of Okhotsk it is called the taiga. To the north, this evergreen forest decreases in height and merges into the tundra. This is a rich commercial forest which supplies large quantities of timber and pulpwood to the world's markets.

Dry Forest.—In the dry areas of the world, particularly where there is a long dry season, the open woodland may be described as the dry forest or the monsoon forest. Extensive areas in southern Asia, Australia, South America and Africa have a hot wet summer that alternates with a dry winter season. Most of the trees in this dry forest lose their leaves during the dry season but come into leaf at the beginning of the rainy season.

Thorn Forest.—Locally within the dry subtropical and tropical areas the limited rainfall of 10 to 20 in. annually may support a thorn forest. A tangle of thorn-bearing trees may make the area difficult to penetrate or cross. These areas have little or no value agriculturally, but limited areas in Africa, South America, Mexico, Australia and Asia produce gums, fruits, rubber and tanbark.

Sclerophyll brushland is a meagre forest of diminutive trees and brush. Since it is characteristic of the Mediterranean borderlands it is sometimes called the Mediterranean forest. The rainfall of these areas varies from 20 to 30 in. annually and in spite of dry summers these lands are well suited to the cultivation of citrus fruits, olives, vegetables and cereals such as wheat and barley. This type of brushland covers important areas of Mediterranean climate in north and south Africa, southern Europe, western Asia, southern California, central Chile and southwestern Australia.

Land Use and Forest Products.—As in the case of the prairies and other rich grasslands, extensive areas that were once forested have been converted into cropland. In China and in many parts

of Europe and the United States the forest has been sacrificed in order that the cultivated lands might be greatly expanded to meet the demand for increasing quantities of food and industrial raw materials. The soils of the forestlands generally were not as fertile as the chernozems and other black and brown soils developed under a cover of grass. However, the soils are easily cultivated and amenable to fertilization so that their productivity can be maintained indefinitely with proper management.

Over the many centuries when the farms of Europe and North America were literally being hewn out of the forest, the need for lumber was met by using the trees from the nearby woods. But as clearing continued and the woodlands were greatly reduced, the need for timber for homes, factories and other structures had to be met by tapping the forest resources of more distant areas. In Europe the great forests of Scandinavia, the Baltic countries and the mountain areas supplied lumber and other timber products for centuries. In eastern Asia the more heavily wooded lands of Hokkaido and the Amur valley and forests in the Soviet Union supply lumber, wood pulp, mine timbers, posts and other wood products to southern Japan and China where local supplies of timber have been largely exhausted. In the United States, after the forests of the northeastern part of the country and the middle west had been greatly reduced, commercial lumbering in the Great Lakes basin provided a rich harvest of white pine and other woods. Lumbering on a large scale spread to the south, to the Rocky mountains, the Pacific northwest and, later, to the northern forest of Canada. *See* FORESTS AND FORESTRY; LUMBERING; ARBORICULTURE; WOOD; RAIN FOREST.

III. ANIMAL LIFE

Before man took possession of the earth and modified the natural environment to meet his needs, the numerous animals were widely distributed in accordance with the suitability of the various habitats and the competitive situation among the animals themselves. The animals of the world, both wild and domesticated, constitute a major biological resource subject to both the laws of nature and the facts of economics and culture. Man in his ignorance or thoughtlessness has brought destruction and virtual extermination to herds of wild animals such as the buffalo and the caribou and to great flocks of waterfowl and other birds. At the same time he has brought his scientific knowledge and management skills to bear upon the animals he wished to retain. At mid-20th century the number of cattle in the world reached an estimated 972,000,000 head; sheep numbered 917,000,000; and swine, representing one of the major food animals of the world, totaled 386,000,000. These and other animals available to the more than 2,600,000,000 people in the world constitute a viable resource of immense worth. Yet among the animals of the earth there are predators, insects and microscopic forms of life which may challenge man's mastery over the animal kingdom. The predators may serve to hold in check the rate of growth of certain animals which might become destructive. Among the insects there are some such as the bees that are of great value, but others may be the carriers of disease germs causing unnumbered deaths each year. Man's control over the animals of the world is partial rather than complete and in effect he may be in competition with other animals, particularly the insects, to see which shall win supremacy.

In nature, without any interference from man, wild animals established a living relationship with the environment, both physical and biological. Over a long period of time the animal populations evolved from more primitive ancestors and became dispersed over the earth in relation to the favourable and limiting conditions of the environment. A habitat that is particularly favourable in respect to the essential requirements of a single or a number of species may become fully populated in a relatively short period of time. Conversely, an environment that is repeatedly subject to extremes of temperature or moisture may be sparsely occupied, and the native and migrant animals may be subject to restrictions on continued increase in numbers. Under natural conditions something in the nature of a biological balance is achieved, but this nice relationship can easily be disturbed by a change in the physical habitat or by a devastating disease that may weaken or decimate an animal group. The science of animal ecology is concerned with the relation of animals to the conditions of the environment, both physical and biological. (*See* ECOLOGY.)

Habitat Factors.—All animals are dependent upon an adequate supply of oxygen and water to meet their essential physiological needs. The temperature conditions of the habitat must have limits that can be tolerated by the animal community. Through the process of natural selection only the fittest survive. By this means a species retains its competitive advantage. The food supply must be adequate and available at the usual and necessary feeding times to maintain the animal populations. Whereas many animals such as the carnivores feed upon other animals, fundamentally they are all dependent upon adequate supplies of plant substances for continued existence. From the smallest and lowliest forms of life to the largest predators there are animals that derive their food from other animals, many of which are plant eaters. In the sea, the larger fish and other forms of life are dependent upon the availability of smaller animals, particularly fish, to maintain life but the smallest animals of the sea are dependent upon plankton (*q.v.*) and other very tiny forms of life.

Domesticated Animals.—When man began to domesticate animals and use them as a means of livelihood for himself, his family, his tribe or his group, economics became a factor in the life of the people. Before this time only natural factors had significance in the evolution, dispersal and relative abundance of the many animals that populated the earth.

Man in his early evolutionary history became a meat eater and satisfied his need for this type of food by hunting and fishing, two occupations that have continued to the present time. The domestication, breeding and the biologic and economic development of a number of animals have contributed immense quantities of animal products to the food resources of the world and introduced a stabilizing factor in the animal food industries.

The principal animals that have been domesticated include poultry, swine, cattle, water buffaloes, horses, sheep, goats, camels, the Tibetan yak, reindeer and llamas. It was largely because of man's need for a work animal and a burden bearer that several animals were domesticated, although some of these same animals also contributed products such as wool, milk, meat and hides.

Animal Power.—Domestication of animals was for companionship, for hunting, for food and for transportation. The principal work animals for centuries have been horses, cattle, water buffaloes, camels, llamas and elephants. In the densely populated areas of the orient where manpower is relatively abundant and food resources are limited, the larger work animals such as horses and oxen have been eliminated or are maintained in limited numbers only. Water buffaloes, because they are particularly well suited for work on the wet rice lands, have been retained. In parts of the tropics, because of the climatic conditions and the economic status of the people, oxen have continued to be an important source of power.

Into the early 19th century, oxen were also widely used as work animals in much of Europe and America, but they were shortly displaced by the horse. Prized for its speed, endurance, longevity and intelligence, the horse became the principal work animal throughout west and central Europe, much of Russia, in the United States and in the intermediate latitudes where European culture spread. When the European or American farmer prospered he gave up the slow plodding oxen for the horse, which was able to hold its own until the development of the tractor and the subsequent mechanization of agriculture.

Animals as a Source of Food.—The use of animal products for food is largely the result of cultural inheritance. Taboos of cultural origin may limit the consumption of certain foods which, from the nutritional point of view, are edible. For example, certain visceral organs may not be acceptable in the diet of some people but may be regarded as a delicacy by others. In India, where cattle are most numerous, the use of meat for food is restricted. On the other hand, Eskimos and other peoples far removed from foods of plant origin are heavy consumers of meat.

Although there are millions of people who do not eat meat be-

cause of religious prejudice or personal preference, meat in varying amounts is consumed widely throughout most parts of the world, depending on its relative abundance and its cost in relation to other available foods. While it is most economical for man to derive his foods directly from plant sources, there are many plants that he cannot eat. Animals act as intermediate processors of such plant foods as the coarse feed grains.

The rich agricultural lands of the world that were once in forest or in grass are now the leading producers of meat animals. Cattle by the millions are raised on the farms and ranches of the United States, Canada, Mexico, Argentina, Uruguay and Chile and on the extensive grasslands of the tropics. In Europe from the Atlantic to the dry steppes of the Soviet Union cattle are raised for dairy products, for meat and as sources of power.

Swine and poultry are more economical in the utilization and conversion of feed into edible products than cattle. Both are scavengers and make use of food materials that would otherwise go to waste. Both reproduce rapidly and mature quickly. When there is a need to increase the quantity of foods of animal origin, it can be done more quickly with swine and poultry than with cattle. In China, Europe and the United States swine and poultry are raised in great numbers though the feeds used differ from country to country. In China these animals are scavengers but in the U.S. quantities of grain are used for feed. In Europe the by-products of the dairy industry, locally grown and imported grains and wastes from the table support the two industries.

The intensive development of animal industries is a means of maintaining soil fertility if the methods of cultivation are nondestructive. By giving the animals the feeds grown on the land and by returning all manures and other organic wastes to the land, the soil, by means of the livestock industry, may be regarded as a renewable resource, and with proper management is virtually inexhaustible.

Fisheries.—The animal resources of the sea have been used for human food for centuries. The most important fisheries are located in the northern hemisphere between 40° and 60° N. where the cool waters of the North Atlantic and the North Pacific cover extensive areas of the continental shelf and where plankton and other foods are relatively abundant. They include the North sea and the shallow waters off the coast of Europe, the Grand Banks south of Newfoundland and other nearby coastal waters, the shallow coastal waters along western North America and favourable waters around Japan and the seas adjacent to the mainland of northeastern Asia. Through the years certain species such as cod, salmon and halibut have been taken in such quantities that the fishery resources have been reduced and require regulation to maintain their continued productivity.

In somewhat warmer latitudes the shellfish industry contributed important quantities of lobsters, oysters, clams and crabs to the food resources of the world, but depletion has been a threat to the industry. In Japan, western France, northwestern Washington and Chesapeake bay the oyster industry has been brought under control and a continued supply is assured. In the warm waters of the tropics fish are not as abundant as in the cooler waters of the intermediate and higher latitudes, but fish caught in local waters are important in the diet of the people. The tuna fishery in the Pacific and the shrimp industry in the Gulf of Mexico provide valuable foods prized by millions. *See* ANIMALS, DISTRIBUTION OF; ZOOGEOGRAPHY; FISHERIES; FISH CULTURE; ANIMALS, DOMESTICATION OF.

IV. WATER

Approximately 71% of the surface of the earth is covered by the oceans. These extensive salt-water areas function in various ways in the affairs of men. The broad seas serve or did serve to separate the continents and the nations that have divided the land areas of the world among themselves. The size and the distribution of the seas affect in various ways the climatic conditions of the earth and influence, as a consequence, the character of the soils, natural vegetation, agriculture and commerce. Also, the sea is a reservoir of mineral resources, but only a few, such as salt and magnesium, have been recovered.

The fresh waters that lie upon the land in the form of streams, lakes, ponds, swamps, springs and reservoirs and the ground water that occurs beneath the surface constitute the water resources of the land, though the saline waters of inland seas and subsurface structures have commercial value also.

If all the fresh water on the land and the quantity contained in the rock formations could be calculated accurately, it probably would not exceed much more than 1% of the total water on the earth. Fresh-water resources become available through the operation of the hydrologic cycle. The energy of the sun evaporates enormous quantities of water from the sea and the resulting vapour becomes a part of the atmosphere. The winds distribute this vaporous moisture widely over the earth. Upon condensation and precipitation, 30% of it is returned directly to the sea. Out of the water vapour that is transported over the land areas, precipitation provides varying amounts of fresh water for use by man. Of the water that falls on the land an important fraction penetrates the soil, percolates downward to levels below the root zone and becomes, temporarily at least, a part of the reservoir of ground water.

Under favourable topographic and geologic conditions, some of the ground water returns to the surface in springs, many of which, because of their perennial character, contribute to the regularity in the flow of streams. Waters that penetrate deeply may be returned to the surface by the numerous wells that have been put down in thickly settled areas to provide the people with potable water. By evaporation and by transpiration some water is returned to the atmosphere, but much of it becomes runoff and returns to the sea, thus completing the hydrologic cycle.

Water is a multiple-purpose resource that may be made to serve a number of functions on its way to the sea. Water on the land supports vegetation and if it is more abundant than is necessary for agriculture it may form a habitat for aquatic plants and animals. Only to a limited extent is water an industrial ingredient, but it does serve as a source of power and as a coolant. Water of the larger streams and lakes may be used to supply the culinary and personal needs of people in urban communities and the wastes from cities are discharged into these same streams and water bodies. Abundant supplies of water are required in a sanitary system to treat the sewage, dilute the effluent and flush away the wastes. In quantity, the fresh waters of the earth bear a significant relationship to the amount of precipitation that falls upon the land and its seasonal distribution. When the first land areas were uplifted above sea level, fresh water began to enter the pore spaces and other cavities in the various geologic formations. Originally most formations, especially those originating through deposition of sediments in the oceans and saline seas, contained salt water. But as fresh water penetrated these aquifers and moved along under hydrostatic pressure, most of the salt water was gradually replaced by fresh water. In the deeply buried formations salt water is still trapped and there is very little prospect that these saline waters or brines will ever be replaced by fresh water. Some rock formations contain soluble minerals that are taken into solution by the deeply penetrating fresh waters that originally fell as rain. These brines, whether they represent deeply entrapped sea water or solutions containing saline materials from the country rock, constitute an important natural resource.

Where thick layers of sedimentary and other porous rocks are so disposed structurally that surface waters are readily absorbed and penetrate deeply, the total quantity of underground water may be enormous. This reservoir of ground water is in a sense a capital fund that can be drawn upon to meet local and regional needs for water. The earth materials into which the surface waters penetrate filter and purify the water and make it readily usable for most culinary and industrial purposes. However, the water may contain sufficient mineral matter such as lime carbonate and other salts to make it hard and unsatisfactory for particular purposes unless treated.

The fresh water on the land in the form of streams, lakes, ponds and marshes represents only a fraction of the total rainfall. Like springs, lakes, ponds and marshes help to steady the flow of streams. These natural regulators have been supplemented by the construction of dams both large and small to hold back the

water in times of heavy precipitation so that adequate supplies may be available for power, irrigation, industrial and culinary purposes in times of low rainfall.

The total power derived from falling water is relatively small when compared with the power available from coal, petroleum, natural gas and atomic sources, yet certain countries such as Italy, France, Switzerland, Norway, Sweden, Canada and Japan are heavily dependent upon water power. In the mid-1950s the capacity of the water-power plants in the United States was in excess of 130,000,000 h.p., a little more than one-quarter of the world total.

Inland waters have long been highways of commerce. In the United States other means of transportation, except on the Great Lakes, have competed strongly with the waterways. In Europe, waterways, both natural and man-made, are relatively more important. But throughout history the great rivers of the world, such as the Rhine, the Volga, the Yenisei, the Yangtze, the Nile, the Amazon and the Mississippi, have been arteries of trade.

As the demand for water increases, the available supplies will need to be more carefully utilized. With proper treatment, water may be used over and over again as it moves downstream toward the sea. By cloud seeding in areas where conditions are favourable, the amount of precipitation may be increased slightly. By desalting saline waters the quantity of fresh water may be increased, but except in areas of scant supply where desalting may be practical, the immediate needs for more water will probably be met by the treatment and reuse of known supplies. *See* WATER; GROUND WATER; HYDROLOGY; OCEAN AND OCEANOGRAPHY; WATER SUPPLY AND PURIFICATION; and individual articles on hydrographic features.

V. MINERALS

In order to simplify this discussion of minerals, the great variety of inorganic substances contained in the earth's crust and the seas is treated in a limited number of categories: mineral fuels, iron and the ferroalloys, the nonferrous metals, the precious metals and the nonmetallic minerals.

Mineral Fuels.—*Coal.*—The coal resources of the world are essential to continued industrial development. Petroleum and natural gas, and to a limited extent water power and nuclear fuels, supplement coal, but the strong industrial nations must have access to this essential industrial fuel.

All coal, whether classed as anthracite, bituminous or lignite, is derived from vegetable matter accumulated and preserved under favourable geologic conditions. To be regarded as workable resources for the foreseeable future, the coal must occur at depths not exceeding 6,000 ft. beneath the surface and under structural conditions that will permit economic mining at the greater depths. The thickness of the seams or layers is an important factor in the economic production of coal, particularly in deep mines.

The leading producers of coal are the United States, Germany, the Soviet Union, the United Kingdom and Poland, all of which produce from 100,000,000 to more than 400,000,000 tons annually. Smaller quantities, generally under 100,000,000 tons annually, are produced by China, India, Japan, Czechoslovakia, France, Belgium and Australia.

The reserves of coal yet to be developed are similarly distributed over the world. In North America, chiefly in the United States, more than 2,000,000,000,000 tons of coal remain to be mined. In the Soviet Union and China the reserves total more than 2,400,000,000,000 tons, enough to meet the needs of these two great powers for many decades or even centuries. In Europe significant reserves are located in Germany, the United Kingdom and Poland. In the southern hemisphere large reserves are available in Australia and South Africa.

Petroleum.—Like coal, petroleum is believed to be of organic origin. Because it is a liquid it can be transported in pipelines, tank cars, barges and tankers. The refining of petroleum consists of distilling or fractioning off the various liquid constituents and of cracking, a process in which the heavier oils are used to produce the lighter products such as gasoline, kerosene and fuel oil which are in great demand. From petroleum are derived a number of basic raw materials used in the manufacture of plastics, detergents, synthetic rubber, explosives and dyes.

Petroleum occurs in porous sandstones and other formations with large and abundant interstices. Early man used limited quantities of petroleum as an illuminant, as a lubricant and for pharmaceutical purposes. The first well drilled specifically for oil was put down at Titusville, Pa., in 1859. For 100 years the United States has held the leadership in production except for a brief period from 1898 to 1901 when leadership passed to Russia. The principal petroleum producers are the United States, Venezuela, Saudia Arabia and Kuwait, the Soviet Union and Iraq. Others of importance include Canada, Mexico, Rumania, Indonesia and Iran. From 1918 to 1926 Mexico was second to the United States, only to be surpassed by the Soviet Union. The relative decline of Mexico was offset by the rise of Venezuela, which achieved second place in 1944, a position it continued to hold.

The ease with which crude petroleum can be transported makes it possible to concentrate refining capacity in or near the market areas. Approximately half of the world's refining capacity is located in the United States. Other major refinery centres are in the Soviet Union, the Netherlands Antilles (Curaçao and Aruba), Canada, the United Kingdom, France, Italy, Japan and Iran (Abadan).

The reserves of petroleum are unequally distributed over the earth. The United States, long a leading producer, has less than 20% of the world's known reserves. The middle east countries, having achieved recently a high place among producing areas, have approximately 66% of the reserves. The proven reserves in the Soviet Union amount to only 5%, though future exploration may increase them greatly. In South America, particularly along the eastern margin of the Andes, reserves of petroleum may maintain production for many decades.

Natural Gas.—In most petroleum areas natural gas is available for use as a fuel and as a raw material. Outside of the Soviet Union, for which production data are not available, natural gas is produced chiefly in the United States, Canada, Mexico, Venezuela and Italy. In the United States natural gas from Texas, Louisiana, New Mexico, Kansas and Oklahoma is distributed by pipeline to the industrial and domestic consumers in the northeast including New England, the south, the middle west and the Pacific coast. Production of natural gas in the United States in 1957 amounted to 10,200,000,000,000 cu.ft.

The recoverable reserves of natural gas in the United States were estimated to be 446,500,000,000,000 cu.ft. in the late 1950s. New discoveries in the southwest and California have increased U.S. proven reserves substantially.

Atomic Energy.—Uranium (*q.v.*) is the chief source of atomic energy though thorium and other radioactive minerals may be used as fissionable fuel. The known quantity of uranium in the earth's crust is equivalent to 0.008%. It is twice as abundant as zinc and many times more abundant than the precious metals. However, it is widely distributed and only in a few places is it sufficiently concentrated to warrant development and production. It has been estimated that the total heat energy available from the reserves of atomic minerals may be as much as 25 times that available from the known reserves of coal.

Atomic energy thus far has been used chiefly for weapons, but a number of reactors are being used as sources of power in electrical generators and on submarines. It will continue to be used for these and other purposes, but in the United States and other countries where other sources of power are available at low cost the use of atomic energy may be restricted for some time to come.

Uranium is recovered from deposits of pitchblende which occur in the Republic of the Congo, Canada and Czechoslovakia. In the United States, uranium ores are contained in the thick sedimentary formations of the Colorado plateau of western Colorado, New Mexico and Utah. Other sources of uranium are in the Republic of South Africa, Australia, France and Portugal. (*See* FUELS; COAL AND COAL MINING; PETROLEUM; GAS INDUSTRY; ATOMIC ENERGY.)

Iron and the Ferroalloys.—*Iron.*—In the earth's crust iron is one of the most abundant metals, exceeded only by aluminum.

Whereas iron as an element is widely distributed, the major iron minerals such as hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite ($Fe_2O_3H_2O$), siderite ($FeCO_3$) and others are concentrated in rich ore deposits in a limited number of places. The richest ores, consisting chiefly of magnetite, contain 60% to 70% iron. Hematite ores seldom contain metallic iron in excess of 60%, and the poorer or leaner ores may contain as little as 20%–25%. When the iron content is under 25% the ores may be described as uneconomic or submarginal. In the United States ores under 35% iron are seldom used unless first treated to enrich them.

With the exhaustion of the rich ores in the iron ranges of the upper Lakes area in Minnesota and Michigan, the iron-bearing taconites and jasperites have become potential sources of iron. These iron-bearing formations are crushed and by magnetic and other means of enrichment the iron minerals are concentrated and pelletized by a sintering process so that the resulting ore can compete with the naturally rich ores. Domestic sources of iron ore have been unable to meet the demand and as a consequence foreign ores to the extent of 15,000,000 tons annually are imported from Canada, Sweden, Venezuela and Chile and from a number of countries that supply only limited quantities of ore.

With the completion of transportation facilities from the Gulf of St. Lawrence to the rich iron resources along the Labrador-Quebec boundary, the Knob lake ores have become available to Canadian and U.S. blast furnaces. Other Canadian ores are mined in the Steep Rock and Michipicoten areas in the Lake Superior upland. The Wabana ores of Newfoundland have long been available to furnaces in eastern Canada.

In the Latin-American countries important iron deposits in the Cerro Bolívar area of Venezuela have become available for domestic use and for shipment to the U.S. Iron ores are also produced in Chile and Brazil. The rich resources of Venezuela and the state of Minas Gerais in Brazil constitute a major reserve that may be drawn upon to support the iron industry of the future.

In Europe the chief centres of iron-ore production are in the United Kingdom, France, Germany, Sweden and the Soviet Union. In western Europe the Minette ores of Lorraine have long held first place as a source of iron. Other contributors include Spain, Italy and Austria. The Soviet Union is the leading producer of iron ore in Europe with the Krivoi Rog of the Ukraine and the Magnitnaya and other centres in the Urals accounting for most of the production. Large reserves of iron ore are known to exist in the Soviet Union so that its iron and steel industry will be adequately supplied with ore in the future.

Ferroalloys.—Limited amounts of a number of ferroalloy metals are required to produce the specialty steels needed by modern industry. These metals include manganese, chromium, nickel, tungsten, vanadium, molybdenum and cobalt.

Manganese is used as an oxidizer and as an alloy and is required in the manufacture of all steel. In the late 1950s manganese ores were mined in the Soviet Union, India, Brazil, South Africa, Ghana and Morocco. Chromium, used with nickel to make stainless steel and as a plating metal, is available in quantity in the Philippines, Turkey, the Republic of South Africa, Southern Rhodesia and the Soviet Union. The Sudbury area of Canada produces nearly 60% of the world's nickel. Smaller quantities are produced in Cuba, the Soviet Union and New Caledonia. Tungsten, important in the manufacture of tungsten carbide and as an alloy, is widely distributed but for many years China has been a principal supplier of this metal. Other producers include the Soviet Union, the United States, Bolivia, Portugal and the Republic of Korea. Molybdenum, like nickel, is highly concentrated in a single mining centre, Colorado. More than 95% of the world's molybdenum is produced in the United States. Vanadium, which imparts strength and resilience to steel, is produced chiefly in the United States, Peru, southwest Africa and Finland.

These ferroalloys, considered together, are widely distributed among many nations, but the major steelmaking countries are largely dependent upon imports to meet their needs. For example, the United States produces only molybdenum and vanadium in sufficient quantities to meet its requirements. All the other ferroalloy metals must be imported. (*See* IRON; ALLOYS; ORE DEPOSITS; and articles on the various minerals and ferroalloy metals.)

Nonferrous Metals.—These, including copper, aluminum, lead and zinc, tin, mercury, magnesium and several others, have become essential to modern industry. In the early history of man the metals that occurred in the native state such as gold, silver and copper were used for decorative and practical purposes. Either by accident or intention, copper and tin were combined to produce bronze, a metal of immense cultural and economic importance. In time other nonferrous metals acquired industrial importance. These include lead and zinc alone or in combination with other metals, aluminum, magnesium, tin and several more.

Copper.—Because of its superior quality as an electrical conductor and its usefulness as sheet metal and as a component metal in a number of alloys, copper ranks high among the nonferrous metals. Copper as a metal was known and used before the Christian era but its use in quantity came with the development of the electrical industry. Only limited quantities of copper are produced in Europe, where the mining and smelting of copper were developed early. With the development of practical methods of processing low-grade ores, many formerly uneconomic deposits have become major factors in the mining industry. The leading producers are the United States, Chile, Northern Rhodesia (Zambia), the Soviet Union, Canada and Republic of the Congo.

Aluminum.—The difficulty of separating aluminum from bauxite and a number of other aluminum-containing minerals deferred its industrial use for many centuries. The lightness of aluminum, its conductivity and its resistance to corrosion led to its use as sheet metal, for electrical equipment, in transportation equipment and for a variety of products. Bauxite, the chief source of aluminum, is produced chiefly in Jamaica, Surinam, British Guiana, France, the United States and the Soviet Union. In the production of aluminum metal the United States, Canada, the Soviet Union, west Germany and Norway, all producers of cheap electrical power, are the leading contributors. The major producers and users of aluminum are dependent upon imported raw materials with the exception of France and the Soviet Union, which are generally self-sufficient.

Lead and Zinc.—Modern industry continually requires supplies of lead and zinc. In the mid-1950s approximately 2,400,000 tons of lead were produced annually. The leading countries included the United States, Australia, the Soviet Union, Mexico, Canada and South Africa. In spite of the threat of rapid depletion of reserves, production of lead increased through the extension of known reserves and the recovery of a higher proportion of the metal in the ores.

Despite competition from aluminum and other metals, corrosion-resistant zinc is extensively used for galvanizing. Along with copper, zinc is used in the manufacture of brass. Nearly 40% of the world's zinc is produced in North America with the United States in first place. Large quantities are contributed by Canada and Mexico. The continent of Europe produces 32% of the world's supply with important contributions from the Soviet Union, Poland, Italy, Spain and west Germany. In Asia, Japan is the leading producer but larger quantities are mined in Australia. In South America, Peru is the major source. In tonnage zinc exceeds lead but both serve particular purposes in industry.

Tin.—The mining of tin ore is highly concentrated in a few centres but the metal is marketed in all parts of the world. Major production areas are in Malaysia, Indonesia, Bolivia and Republic of the Congo. During World War II Japan controlled the tin resources in the far east. The United States and many other countries had to reuse tin already on hand by detinning tin cans and recovering the metal from collapsible tubes and other sources. The U.S. built a tin smelter at Texas City, Tex., and processed imported ores, chiefly from Bolivia, to help meet its needs.

Other Nonferrous Metals.—The list of nonferrous metals could be extended to include magnesium, antimony, mercury and several others, but the metals discussed above are of major importance and are representative of this group of metals. (*See* ORE DE-

POSITS and articles on the various nonferrous metals.)

The Precious Metals.—Because of the nonperishable character of gold and its use as a monetary standard, the total quantity of metal in the world accumulates over the years. Small quantities are consumed, dispersed or lost each year but generally the total supply of gold in the world tends to increase. New gold comes chiefly from the Republic of South Africa, the Soviet Union, Canada and the United States.

While silver does not enjoy the preferred status of gold as a monetary metal, it is widely used in domestic and international transactions. In addition to its monetary use, it is also used extensively in the arts: for tableware, jewelry, photographic film and other purposes. Some silver occurs in nature as a pure metal but more often it is only one of several metals occurring together as sulfides. Mining, smelting and refining of these ores results in the recovery of copper, nickel, lead and zinc as well as silver. North America is the leading silver continent. Mexico, the United States and Canada usually rank as first, second and third, respectively, in the mining of silver ores. Other producers include the Soviet Union, Peru, Australia and Bolivia.

Platinum, osmium, iridium, rhodium, ruthenium and palladium collectively make up the platinum group of metals. These metals are of major importance in the electrical industry, in the chemical industry, chiefly as catalysts, in the arts, especially jewelry manufacture, and in dentistry and medicine. They are most widely used in the industrial countries. Production is highly centralized in the Republic of South Africa, Canada, the Soviet Union, Colombia and the United States. (*See* articles on the various precious metals.)

Nonmetallic Minerals.—The common earth materials such as rocks of various kinds, unconsolidated sediments such as sand and gravel, and clay and silt are so abundant in most parts of the world that any needed material not available locally can be obtained from nearby areas. Generally these earth materials are low-value, short-haul resources. Only a few, such as china clay, decorative stone and others that may have some special quality, can be transported over great distances economically.

Among the nonmetallic substances present in the earth's crust, a few have special qualities which make them vitally necessary in industry. Among these are such minerals as asbestos, sulfur, quartz crystals, mica, salt, the fertilizer minerals and several others.

Sulfur.—Modern industry is heavily dependent on sulfur for its proper functioning. Sulfur is obtained chiefly from deposits of elemental or native sulfur and from sulfur-containing minerals such as the sulfides. Along the Gulf coast of Louisiana, Texas and Mexico are numerous salt domes that contain native sulfur. This coastal strip is the world's leading producer. Other major producers of native sulfur are Italy, chiefly in Sicily, and Japan, where the deposits are associated with volcanic rocks. More widely over the world the processing of sulfide ores yields important quantities of sulfur. This is done in Spain, a long-time producer, Canada, Japan, the United States, the Soviet Union, Norway and the island of Cyprus.

Quartz.—Silica, consisting of oxygen and silicon and commonly occurring as quartz or in silicate minerals, is one of the most abundant earth materials. As quartz sand it is used for a variety of purposes from glassmaking to sandblasting. In spite of its relative abundance in nature, quartz crystals of great purity and large size are relatively rare and production to meet the needs of the electronics industry is largely centred in Brazil. (*See* QUARTZ; SILICA.)

Mica.—A thin platelike mineral, mica is widely known in nature where it occurs in small flakes in igneous and schistose rocks. Sheet mica in large crystals occurs in pegmatite dikes and can be quarried, split and cut to the required dimensions. Large quantities of flake mica are available wherever coarse-grained igneous rocks occur and the needs of the rubber, roofing, paint and abrasive industries can be met from these sources. The high-quality sheet mica used by the electrical industry is produced in more restricted areas including India, Madagascar, eastern Siberia, Brazil and the United States. (*See* MICA; PEGMATITE.)

Asbestos.—Before the development of spun glass and rock wool as noncombustible and heat-resistant materials, asbestos was in high demand for these purposes. Asbestos, because of its fibrous nature, can be spun and woven into heat-resistant fabrics for fire curtains, gaskets, brake linings, fire fighters' suits and many other items. Asbestos in combination with portland cement, magnesia and other substances is used in the manufacture of roofing materials and wallboard. High-quality asbestos is produced chiefly in the Thetford area of eastern Canada, but important tonnages are contributed by the Soviet Union, the southern part of Africa and Japan. (*See* ASBESTOS.)

Fertilizer Minerals.—The continued productivity of the land is dependent upon the availability of four major elements, calcium, nitrogen, phosphorus and potassium, and a number of minor or trace elements including magnesium, manganese, boron, iron, copper, sulfur, zinc and others. Calcium, chiefly in the form of lime carbonate, is relatively abundant and areas without limestone can easily secure this material.

Nitrogen in the form of nitrates is widely distributed in soil but because of its solubility it is continually being lost. The nitrogen content of the soil can be maintained by the application of manures and other organic wastes to the land. Mineral nitrates, available in the Atacama desert of northern Chile, were formerly used extensively in the manufacture of commercial fertilizers. After World War I nitrogen obtained by fixation from the atmosphere became increasingly important and makes up more than three-quarters of the nitrogen content of the commercial fertilizers.

Phosphorus usually is available from phosphate rock which contains the mineral calcium phosphate. In order to make the phosphorus readily available, the phosphatic material is treated with sulfuric or nitric acid. Small quantities of calcium phosphate occur widely in limestones and, as a result of weathering, phosphatic minerals may be residual in the soils locally. Phosphate rock in sufficient abundance to support the fertilizer industry is available in the United States, Morocco and Tunisia in north Africa, the Soviet Union and Nauru in the west central Pacific. Phosphatic material is also available from phosphorus-containing minerals and ores. For example, basic slag from the steel industry may contain enough phosphorus to justify its preparation and use as a fertilizer.

Before World War I Germany had a virtual monopoly on potash but with the loss of Alsace a portion of the production and reserves passed to the jurisdiction of France. Stassfurt, Ger., remains a major source of potash but production from deposits in New Mexico has given the United States second place. Other producers include the Soviet Union, Spain and Israel. (*See* FERTILIZERS AND MANURES; MINERAL PHOSPHATES.)

VI. STRATEGIC RESOURCES

All materials, inorganic or organic in origin, necessary to national defense or the prosecution of war may be said to be strategic. No nation should risk involvement in a major war unless its supplies of strategic materials are adequate for an extended conflict or unless it has the capacity to produce or secure these resources by trade. Certain resources may be available in quantity but they may be regarded as strategic if they are essential to defense or military effort. For example, steel and cotton are strategic materials but in the case of the United States adequate production can be maintained. The resource situation may vary from completely adequate supplies of a number of materials to negligible supplies of others. Because of technological developments, the number of materials that may be classed as strategic has grown, and the problem of securing and maintaining adequate supplies has become increasingly complicated.

Stockpiling.—In the case of scarce materials the resource situation may be so critical that stockpiles of a long list of metals, ores and organic materials should be built up to meet the needs of a nation while it absorbs the first shocks of a major war. Such emergency supplies should be large enough to meet wartime needs over a period of two to five years or even more, depending on the ease or difficulty of securing replacements.

Stockpiles of organic materials such as rubber, fibres, timber, hides and skins, condiments and wood pulp are subject to deterioration or destruction while in storage. For example, the stockpiling of raw rubber requires that a regular and continual renewal program be maintained to keep up the quality of a nation's hoard of this essential commodity.

The program of stockpiling of strategic materials should be reexamined from time to time to make sure that the proper quantities are maintained. People can be lulled into a false sense of security by the knowledge that the strategic materials have been stockpiled. As the needs of defense change the character and dimensions of the stockpile will need to be restudied.

Substitution.—If metals and other materials are not available in sufficient quantities to meet defense needs, the national security may be endangered. Substitute materials should be included in the stockpile or be in production so that the national economy will not suffer if it becomes necessary to substitute one material for another. If all of the ferroalloys are not accessible in the proper quantities the steel industry may make more abundant use of the alloy metals that are available. This in effect is the substitution of an abundant metal for one in short supply. During World War II, when the supply of tin was greatly reduced, glass containers and lacquered cans replaced the widely used tin can. It is evident that plastics can be used extensively to replace metals and wood. Continued research and technological developments will provide a variety of substitute materials when the need arises.

Subsidies.—In some instances a mining operation or manufacturing facility engaged in the production of a strategic material may be in financial difficulties. A modest subsidy may be all that is required to give such an industry economic stability and the prosperity it requires to continue in operation.

Trade and Tariffs.—National security for all nations, even such powerful countries as the U.S. and the U.S.S.R., depends upon international trade. Materials in short supply are imported and inventories and stock piles built up. To encourage this, nondiscriminatory tariffs and other politico-economic devices may be used to facilitate the movement of essential materials. *See* ECONOMIC WARFARE; MOBILIZATION, ECONOMIC.

VII. CLIMATE

On the basis of temperature and rainfall, the earth can be divided into a variety of climatic regions. Five major thermal zones may be identified: the tropical zone, the north and south intermediate zones and the north and south polar zones. On the basis of precipitation, the earth can be divided into rainfall regions: humid, subhumid, semiarid and arid. By combining temperature and moisture conditions the earth can be divided into approximately 15 major types of climate though individual climates may be repeated over the surface of the earth as many as five or six times.

Humid Tropical Climates.—Between the equator and approximately latitude 18° to 20° north and south lies an area with a humid tropical climate. Near the equator the climate is rainy at all seasons because the area is always under the influence of the doldrums. The annual amount of precipitation varies between 60 and 100 in. except in mountains where the maximum may exceed 300 in. In these equatorial areas the precipitation in the driest month may be as little as three inches in the low-sun period. When the sun is directly overhead the amount of precipitation may exceed ten inches per month. These wet equatorial climates are well developed in the Amazon basin and nearby coastal areas, in the Republic of the Congo and the borderlands of the Gulf of Guinea and in Indonesia, the Philippines and the coastal margin of southeast Asia.

Generally poleward from the equatorial climates there are extensive areas that have a savanna type of climate, a name that indicates the character of the natural vegetation. These areas have a hot climate the year around with a precipitation of 30 to 60 in. The rainfall is heavily concentrated in the summer season or the high-sun period. When the sun is low in the sky and the trade winds prevail, these savanna areas are very dry. The savanna type of climate is characteristic of large areas in South America such as the llanos and the campos and of many areas in Central America and the Caribbean. The Sudan and the plateaus of east and south central Africa contain extensive savanna areas. Large areas in India, southeast Asia and northern Australia also have this type of climate.

Dry Climates.—Large areas in the trade-wind belt and in latitudes 15° to 30° north and south are characterized by desert or semiarid conditions. These dry areas extend generally poleward into the interior areas of the continents of South America, North America and Asia. Those that lie between the true deserts and the humid areas near the coasts are semiarid and characterized by the scant vegetation of the steppe.

Humid Climates of Intermediate Latitudes.—On both the west and east sides of the continents in latitudes 30° to 65° north and south the precipitation varies from 20 to 80 in. annually. In these latitudes the annual range of temperature is much greater than in the tropics. Along the west coasts temperatures are more moderate than on the east coasts, where continental extremes are common. Summers are hot and winters cold. On the west coasts the maximum precipitation comes in the winter season but on the east sides of the continents precipitation is more evenly distributed throughout the year. Interior locations generally have a warm-season maximum.

Polar Climates.—In the arctic and antarctic areas, where the sun is continuously above the horizon for as much as six months and is below the horizon for a similar period of time, the climate is characterized by a low mean annual temperature and even in summer the temperatures are low. The winters are long and bitterly cold. Limited areas that are free of ice and snow during the short summer have a tundra type of climate. Extensive areas are always covered by ice and snow and have an icecap or glacial climate. *See* CLIMATE AND CLIMATOLOGY; SEASONS; METEOROLOGY.

NATURAL RESOURCES, LAWS CONCERNING (U.S.). This article deals with the roles of the federal and state governments of the United States in the conservation of such natural resources as soil, forests, water, range land and minerals (including oil and gas). The dual authority of the two governments to legislate on conservation has created numerous legal complications. On the one hand, the federal government admittedly possesses broad power to provide for the conservation of

resources on land that it owns and that it acquired through cession or conquest (the public domain) or on land that it has purchased from private owners (acquired land). The extent of its constitutional power to provide for conservation of resources on land that has passed into private ownership is much less clearly defined. A state government also may have relatively broad powers of conservation with respect to land that it owns, but its conservation legislation relating to privately owned resources may sometimes conflict with provisions of the federal constitution.

State Legislation.—Under its police powers a state may eliminate threats to its resources without violating the due process clause of the federal constitution. Thus, in order to control plant and animal diseases, a state may institute inspection or preventive measures or may provide for the destruction of disease-bearing objects. Legislation to prevent physical waste is generally upheld where the resources are publicly owned (*e.g.*, wildlife). With respect to privately owned resources, however, considerable uncertainty exists about the extent to which conservation measures may be applied. The validity of regulations relating to waste of oil and gas has generally been defended on the assumption that these measures really protect other private owners who have correlative rights in the minerals rather than on any general privilege of the state to provide for the conservation of all natural resources within its boundaries. Timber and soil conservation statutes exist in a number of states, and although there has not been much litigation under these measures they are probably valid as long as the interference with property rights is no greater than is reasonably necessary. There seems to be virtually no state legislation conserving the so-called hard minerals.

In contrast to legislation aimed at physical waste, a number of the oil states have proration statutes which are designed primarily to avoid overproduction of oil and gas. These have been upheld on the ground that they also prevent physical waste, but their primary purpose would seem to be to deter economic waste through the control of prices.

An interesting aspect of state conservation legislation is the type of statute which purports to limit the use to its own citizens of resources owned by the state in trust for the public. Statutes which deny nonresidents the privilege of hunting are probably no longer valid, but a higher price for nonresident licenses can be justified on the basis of the increased cost in administering the program. U.S. supreme court decisions conflict on the right of a state to forbid exportation of its natural resources. Legislation of this type is likely to run afoul of the commerce clause in the federal constitution.

The greatly increased national consumption of water has resulted in conservation measures even in states not traditionally classified as "arid." In the western states the right to use water, which is regarded as a publicly owned resource, is in general based on priority of appropriation rather than upon ownership of land which is situated near, or which contains, water. These "appropriation" states make beneficial use the basis, measure and extent of the right to use water, and the basic postulate of their laws is that water may not be wasted even by one who has secured a right to appropriate it. These states have elaborate administrative organizations to supervise the allocation of this vital resource in the public interest. In some of these states, the right to use water may be obtained only after filing an application with the appropriate state official, stating the purposes for which the water is to be used, the type of diversion, the amount of water required and the time when it will be used. Such requirements are, of course, intended to prevent waste and the acquisition of water rights for purely speculative purposes. The major problem in western water law is the extent to which the federal government, in administering the federal public domain, may interfere with the traditional role of the state in allocating water. The famous Pelton dam case (*Federal Power Commission* v. *Oregon*, 349 U.S. 435 [1955]) precipitated the controversy in holding that the federal government was not required to obtain permission from the state to build a dam on a nonnavigable stream on federal land which had been reserved for power purposes.

Federal Legislation.—Congress has increasingly invaded the field of conservation under the commerce, treaty, and spending powers as well as under the "property clause" of the constitution. The latter provides that congress "shall have Power to dispose of and make all needful Rules and Regulations respecting the . . . Property belonging to the United States" (art. iv, sec. 3). There are numerous federal conservation programs involving federally owned land; conservation legislation under the other constitutional powers is less common. The Connolly "Hot Oil" act, referred to below, was based upon the commerce clause. The Migratory Bird treaty of 1916 was a conservation measure. Federal reclamation acts illustrate conservation under the spending power.

Grazing.—During the 20th century it became apparent that the federal range lands in the west were in serious danger of depletion due to overgrazing and other wasteful practices. Uncontrolled grazing on the public domain ended with the enactment in 1934 of the Taylor Grazing act. Although intended primarily as a conservation measure, one of the purposes of the act was to stabilize the livestock industry. The secretary of the interior was authorized to make temporary withdrawals of unappropriated land chiefly valuable for grazing and raising forage crops. He was also empowered to establish grazing districts and to issue grazing permits and licences revocable at will. The secretary has issued detailed regulations (popularly referred to as "the law of the range") relating to such matters as the kind and number of animals that may graze on federal range land, the time when grazing is permitted, etc. The program is administered by the bureau of land management of the interior department. Grazing in the national forests is similarly regulated. These areas are under the jurisdiction of the department of agriculture.

Forests.—U.S. timberlands, like the grasslands, were subjected to astonishing abuse in the 19th century. Great quantities of valuable timberland were disposed of under the public land laws as agricultural land. In order to achieve maximum production, the large lumber companies employed wasteful practices. The land was usually logged and then abandoned, timber was cut before there was need for it, and lower-grade portions of trees were not used. In 1891 the Forest Reserve act authorized the president to reserve federally owned forests from sale. Subsequent legislation provided for the administration of the national forests. The forest service of the department of agriculture was given responsibility for carrying out the program, and numerous special acts established the various national forests. The timber policy of the forest service includes the prevention of wood waste and the maintenance of a healthy relation between the volume cut and the amount of new growth. Timber available for cutting is designated by officials of the service, and contracts for the purchase of this timber are generally let on the basis of competitive bidding, provided the highest bidder has the reputation for exemplary lumbering practices. Conservation techniques include the maintenance of forest and range experimentation stations which have pioneered in the development of fire control equipment, insecticides and sprays. New strains of grasses, as well as reseeding programs, have also been introduced. The record of the forest service in administering the national forests and their grazing lands has been most commendable. (*See* also FORESTS AND FORESTRY: *Forestry.*)

Minerals.—Free mining on the federal public domain has been authorized since 1866, and mining locations for hard minerals are governed chiefly by the Mining law of 1872. The policy of the so-called location laws has been one of unrestricted exploitation of hard minerals. Certain fissionable source materials may be sold only to the federal government, and certain common varieties of minerals have been removed from the location laws. The federal government retains the right, prior to the issuance of a mining patent, to use surface vegetative materials. Petroleum, on the other hand, has always been the subject of conservation legislation. Beginning in 1909, it was thought that the nation's supply of petroleum was in danger of serious depletion, and vast withdrawals were made reserving valuable federal oil and gas land from disposal under the mining laws. Eventually, with the passage of the Mineral Leasing act of 1920, federal oil and gas land was made exclusively leasable. Leases are issued either to the first applicant or on the basis of competitive bidding, depending upon whether

the land is within a known geological structure of a producing oil and gas field. The act requires lessees to use reasonable precautions to prevent waste. Unitization (co-operative pool development) of oil and gas fields as a conservation measure has been fostered by the federal government in the public land states. The Interstate Compact to Conserve Oil and Gas, adopted by the principal oil-producing states, was approved by congress in 1935, and one of the main functions of the Interstate Commerce commission has been to promote the best conservation practices in oil and gas production. The conservation statutes of the states were also implemented by the Connally "Hot Oil" act of 1935, in which the federal government used its interstate commerce power to prevent interstate shipment of "contraband oil" produced in violation of state prorationing legislation. Apart from these instances of federal legislation, oil and gas conservation legislation is found primarily in the state regulatory measures forbidding wasteful practices and providing for prorationing, well-spacing and compulsory pooling.

Soil Conservation.—The federal soil conservation program consists of watershed treatment, soil and moisture conservation, retirement of submarginal farmlands, and the manufacture of fertilizers. Watershed treatment involves revegetation and other soil-conservation measures undertaken to retard runoff and soil depletion in the interests of flood control, water conservation and the improvement of the quality of water sources. Under the Flood Control act of 1936 the department of agriculture was authorized to investigate watersheds. Eleven watershed treatment plans were approved in the Flood Control act of 1944. The extent of federal participation in these plans varied. The Watershed Protection and Flood Prevention act of 1954 replaced earlier legislation, and under it the secretary of agriculture may make surveys and undertake the construction of works of watershed protection and improvement upon the request of a state or other local unit. The act contains detailed provisions relating to the use of federal funds in construction works. A 1938 Flood Control act also authorizes the secretary to participate in emergency watershed treatment work.

Soil and moisture conservation stems from 1935 legislation passed after the great drought and dust blowing in 1933–34 in the southwestern United States. The secretary of agriculture is authorized to carry out measures against the waste of soil and moisture resources on farm, grazing and forest lands. The interior department shares in this work in connection with land under its jurisdiction. The retirement of submarginal land as part of the federal soil conservation program is carried out principally under Title III of the Bankhead-Jones Farm Tenant act of 1937. The secretary of agriculture may acquire, by purchase or otherwise, lands unsuitable for cultivation, improve and develop them and then sell, lease or otherwise dispose of them.

The manufacture and distribution of fertilizers is a part of the soil conservation program and is under the supervision of the Tennessee Valley authority.

Water Resources.—The water resources program of the federal government includes the soil conservation measures indicated above. In addition, the government has engaged in the improvement of navigation under the numerous river and harbour acts. By the time of the passage of the 1950 act the federal government had improved about 28,000 miles of inland and intracoastal waterways and had constructed 490 locks and dams and 270 harbours, at a total cost of about $1,500,000,000.

Prior to 1936, the federal government had embarked upon a number of special flood control projects. The first general flood control act, passed in that year, extended federal flood control work to all inland waters of the country. By mid-century congress had authorized almost 1,000 projects for the various river basins in the continental United States. The largest enterprises are for the Ohio River basin, the Lower Mississippi River basin and the Missouri River basin.

Reclamation has always been a significant part of the federal water resources program. After earlier unsuccessful efforts to stimulate reclamation by the states, congress embarked upon a program of direct federal action in the Federal Reclamation act of 1902. Like earlier statutes, irrigation works were to be financed by the proceeds from the sales of public lands. A new feature was that the federal government, not the states, was to conduct the land sales and construct the irrigation works. Receipts from the sale of public lands in 13 western states were put in a special fund to be used for the construction and maintenance of such works in these states. Under the act the federal government also engages in the sale of irrigation water, which is subject to two conditions: (1) at least one-half of the total area to be irrigated must be actually reclaimed; and no water shall be sold to any one landowner for a privately owned tract exceeding 160 acres.

NATURAL RIGHTS. The doctrine that all men equally are naturally free "to order their actions and dispose of their persons and possessions as they think fit, within the bounds of the law of nature," found its clearest expression in John Locke's *Second Treatise of Government* (1690), from which this passage is quoted. It is characteristic of Locke, as of modern political thought generally, that he conceived of natural law not so much as a law ultimately derived from God and imposing obligations upon men but as a principle self-evident to human reason that all men are "equal and independent" and that "no one ought to harm another in his life, health, liberty or possessions." Since men are by nature "free, equal, and independent" it follows that "no one can be put out of this estate and subjected to the political power of another without his own consent." According to Locke "the great and chief end" for which men agree to form governments, to live in community, "is the preservation of their property."

The doctrine of natural rights stems from the individualism that emerged at the time of the Renaissance and Reformation and the transformation of the medieval Christian theory of natural law (which prescribed conduct appropriate to human beings as creatures of God) into a theory of natural rights (which emphasized the self-evident character of individual freedom and equality). This transformation was accomplished principally by Hugo Grotius (1583–1645), Thomas Hobbes (1588–1679), Samuel Pufendorf (1632–94) and John Locke (1632–1704) (*qq.v.*). The doctrine which in its Lockian form emphasized the natural right to acquire unequal amounts of property, especially in the form of money, appealed to the rising middle classes and helped to supply a justification for capitalism. Although the doctrine was frequently employed in the 19th century by conservative thinkers who sought to justify the economic *status quo*, originally it had radical implications which were fully exploited in the American and French Revolutions.

Locke was defending the Whig revolution of 1688 but his argument was employed in the American Revolution and found succinct summarization in the Declaration of Independence (1776), which states that, "We hold these truths to be self-evident, that all men are created equal, that they are endowed by their Creator with certain unalienable Rights, that among these are Life, Liberty and the pursuit of Happiness.—That to secure these rights, Governments are instituted among Men, deriving their just powers from the consent of the governed,—That whenever any Form of

Government becomes destructive of these ends, it is the Right of the People to alter or to abolish it, . . ." The French National Assembly adopted a similar Declaration of the Rights of Man and of the Citizen in 1789.

The doctrine did not go unchallenged and the English utilitarian Jeremy Bentham characterized natural rights as "rhetorical nonsense,—nonsense upon stilts" (*Anarchical Fallacies*, 1795). One can speak meaningfully, he contended, of legal rights but not of "natural" rights. Despite such objections, which became more numerous in the 19th century, 20th-century thinkers have persisted in proclaiming "the equal and inalienable rights of all members of the human family," a phrase which occurs in the Universal Declaration of Human Rights adopted by the general assembly of the United Nations at its meeting on Dec. 10, 1948, in Paris.

The revolutionary significance of the doctrine of natural rights which emerged in the 17th century was the fact that it sought to ground government upon individual will and consent. Society itself was thought to be the product of a contract; justice was no longer conceived as embodying principles transcending individual will and consent but rather as a reflection of the terms of the contract. In the Christian tradition as reflected in the thought of St. Thomas Aquinas, as well as in the older Aristotelian tradition, the purpose of the state was dictated not by the subjective desires of individuals but by the nature of man and the end for which he is destined. The state was conceived as existing to promote justice among men, to help men to become better human beings, to help unleash their creative capacities for good and to restrain their propensity to do evil. Justice was not a subjective concept but was rooted in objective reality. Within this tradition individuals are conceived as having rights as human beings but the rights derive from duties rather than the duties from the rights.

The proclamation of "equal and inalienable rights of all members of the human family" would appear to stem from the conviction that there are principles of justice which transcend the positive laws of any society, principles which are the same for all men in all places at all times. They provide the inspiration for social justice and the norms for evaluating existing legislation. They are the *raison d'être* of constitutional government.

Difficulties arise when an effort is made, as it must be made in practice, to distinguish between the possession of such rights and their exercise. Not only may the rights claimed by one individual conflict with the rights claimed by another, but questions arise as to the priority to be established among rights. Is "the pursuit of happiness," which the proclamation of human rights is designed to foster and protect, to be conceived in hedonistic terms or in terms of a life of reason or a life of spiritual growth in awareness of God?

There is more widespread agreement concerning the enumeration of human rights than there is agreement concerning their ultimate justification and practical exercise. Ultimately these disagreements reflect basic disagreement concerning what constitutes the good life for man. Much depends upon whether this good is conceived in material or spiritual terms, whether man is conceived to be primarily a producing and consuming animal or a spiritual creature whose ultimate destiny lies beyond life in this world. In speaking of natural rights much hinges upon how "nature" is interpreted, whether we mean by "nature" how men do in fact act when unrestrained by reason or how men ought to act in order to perfect their natural (human) potentialities.

NATUROPATHY, a system of medical thought and therapeutics based upon the use of natural agencies, forces, processes and products. Surgery is not a part of this system. In many places its practitioners are known as drugless healers. Naturopathy is widespread and its literature, which is very extensive, appears not only in English, German and French but in many other tongues as well. The origins of this medical cult are obscure but its roots may be found in the writings of the ancient herbalists and the practices of primitive folk medicine. (M. C. L.)

NAUKRATIS, an ancient Greek settlement in Egypt to the west of the Nile delta. The site was discovered by W. M. Flinders Petrie in 1884 at Kom Gaif just southeast of modern An Nubayrah, about 10 mi. W. of the present Rosetta branch of the Nile; in ancient times it lay on the Canopic branch, now silted up.

Naukratis was not a colony of the usual Greek type but an *emporion*, trading station, at one time possessing exclusive trading rights in Egypt. According to Strabo, the first settlers (*c.* 610 B.C.) were Milesians, favoured by the Saite pharaoh Psamtik I. Ahmose II (569–526) granted land there to Greeks from nine other cities of Asia Minor, who shared a shrine, the Hellenion, and appointed *prostatai* to superintend trading. Greeks from other cities settled there, however; according to Herodotus, the Aeginetans had a separate temple of Zeus, the Samians of Hera and the Milesians of Apollo. The foundation of Alexandria (332) probably caused Naukratis to decline, though there was new building there under Ptolemy II Philadelphus (king 285–246), and the city was still in existence under Hadrian (emperor A.D. 117–138), who adopted its constitution for his new city Antinoopolis.

The site was excavated by Petrie (1884–85) and Ernest Gardner (1885–86), and again by David George Hogarth (1899, 1903). Traces were found of Greek settlement from the late 7th century B.C. onward and of an Egyptian town to the south of the Greek one. Dedications were found to Hera and Apollo, also to Aphrodite and the Dioscuri; an enclosure to the northeast of the town containing dedications to "the gods of the Greeks" was reasonably identified by Hogarth with the Hellenion. Important finds of Greek pottery threw light on the early history of the alphabet and the commercial activity of various Greek states, especially in the 6th century B.C.

(1951); J. Boardman, *The Greeks Overseas*, ch. 4 (1954).

NAUMACHIA, the Greek word for a naval battle (from *naus*, "ship," and *mache*, "battle"), used by the Romans as a term for a mimic sea fight. These entertainments took place in the amphitheatre, which was flooded with water, or in specially constructed basins (also called *naumachiae*). The first on record was given by Julius Caesar (46 B.C.) on a lake which he constructed in the Campus Martius. In 2 B.C. Augustus, at the dedication of the temple of Mars Ultor, exhibited a *naumachia* representing the battle of Salamis, in a basin constructed near the Tiber and used by subsequent emperors. *Naumachiae* were comparatively rare as they involved much expense and preparation. In that given by Claudius (A.D. 52) on the Fucino lake, 19,000 men dressed as Rhodians and Sicilians maneuvered and fought. The crews consisted of gladiators, condemned criminals and in later times volunteers. A large number of the participants were killed; the saying "Hail, Caesar, we who are about to die salute thee!" was occasioned by Claudius' *naumachia*.

Horace mentions a small-scale *naumachia*, representing the battle of Actium, on a pond in a country estate; this was mere play.

NAUMBURG, a town of Germany in the *Bezirk* (district) of Halle which after the partition of the nation following World War II became part of the German Democratic Republic. It lies on the Saale near the junction with the Unstrut about 44 km. (27 mi.) S.W. of Leipzig by road. Pop. (1961 est.) 37,391. Of many historical buildings, the best known is the cathedral of SS. Peter and Paul with four towers and two choirs; built at the end of the 12th century, it is a mixture of the late Romanesque and the early Gothic styles and contains medieval sculptures, including lifelike statues of the founders of the cathedral. The town is on the Leipzig–Frankfurt am Main railway and on main roads. Principal manufactures are textiles and toys. Near the town in the Unstrut valley are extensive vineyard areas. In the 10th century the margraves of Meissen had a stronghold there. The town was established in 1028, became a bishopric in 1029, received town rights in 1142 and was in 1432 for a short time a member of the Hanseatic

league. After the death of the last bishop in 1564 it passed to the electorate of Saxony until 1815, and then to Prussia until 1945.

NAUNDORFF, KARL WILHELM (d. 1845), was the most successful of the so-called *faux dauphins*, or claimants to the identity of the French king Louis XVII (*q.v.*). First recorded in Germany, he lived in Berlin (1810–12), went to Spandau (1812), married Johanna Frederike Einert there (1818) and, having moved to Brandenburg (1822), was arrested on a charge of coining (1824). The charge could not be proved, but in 1825 he was sentenced to three years' imprisonment on suspicion, since the court rejected his claim to be a French prince. Released in 1828, he went to Krossen and began building himself up as Louis XVII.

On the presumption of Louis XVII's death, Louis XVIII (1814) and Charles X (1824) had become kings of France. When the July revolution (1830) made Louis Philippe king of the French, the new regime might have tolerated a challenge to the preceding one's legitimacy so long as its own security was not endangered. With a tale of escape from the Temple and of adventures in obscurity, Naundorff arrived in Paris in 1833 and was accepted as Louis XVII by the latter's former governess. She took him to Prague to see the duchesse d'Angoulême (Marie Thérèse de France, Louis XVII's sister), who declined to receive him. At the trial of a rival pretender in Oct. 1834, a lawyer publicly intervened for Naundorff as Charles Louis, duc de Normandie—though Louis XVII had been named Louis Charles. In June 1836, having filed a suit against Madame d'Angoulême for recovery of her brother's property, Naundorff was deported from France. His papers were seized and held by the police.

Naundorff finally settled in the Netherlands, where he invented a projectile weapon and sold it to the ministry of war. He died at Delft on Aug. 10, 1845. His numerous descendants pursued his claims, bringing lawsuits in France, with Jules Favre (*q.v.*) as their advocate, in 1851 and in 1874, issuing a manifesto (1883) and petitioning the senate in 1910. Their cause won some passionate adherents, and the periodical *La Légitimité* (1883–1940) was devoted to it. A major counterblast was G. de Manteyer's *Les Faux Louis XVII* (1926), with its mass of documents purporting to equate Naundorff with a certain Carl Benjamin Werg. Even so, Naundorffism was still, decades later, a recurrent manifestation of what its opponents call *fauxdauphinomanie*.

BIBLIOGRAPHY.—For an introduction, *see* L. Creissels, *Louis XVII et les faux dauphins* (1936); L. Hastier, *La Double Mort de Louis XVII* (1951). For a vindication of Naundorff, *see* A. Decaux, *Louis XVII retrouvé: Naundorff roi de France* (1947).

NAUPLIA (modern Gk. NAVPLION), chief town of Argolis *nomos* (department) in the Peloponnese, Greece, at the head of the Gulf of Argos (Argolikos Kolpos), of which it is the port. Pop. (1961) 8,918. It stands on a peninsula between two rocky citadels: Itch Kale, the lower, was the ancient acropolis; Palamidhi, the higher, is named after Palamedes, son of the hero Nauplius (from which the town gets its name), who sailed with the Argonauts. The tiny island of Bourtsi (Bourdzi) in the bay has a Venetian fortress. Nauplia markets the fruit, tobacco and cotton produced in the plain of Argos and is a centre for tourists visiting Mycenae, Tiryns, Argos and Epidaurus (*qq.v.*). The museum has a fine collection of Mycenaean pottery. Nauplia shared the fortunes of Argos in classical times, but revived under the Byzantine empire. Captured in 1210 by Geoffroy de Villehardouin, it became, with Argos, a fief of the French duchy of Athens. In 1388 it was bought by the Venetians, who called it Napoli di Romania. Given to the Turks in 1540, it was recaptured by Venice in 1686, and the Palamidhi rock was fortified. In 1715 it fell again to the Turks, but the Greeks captured it during the War of Greek Independence in Dec. 1822. From 1829 to 1834 it was the seat of their government. The Greek garrison of Nauplia began the revolt against King Otho in 1862.

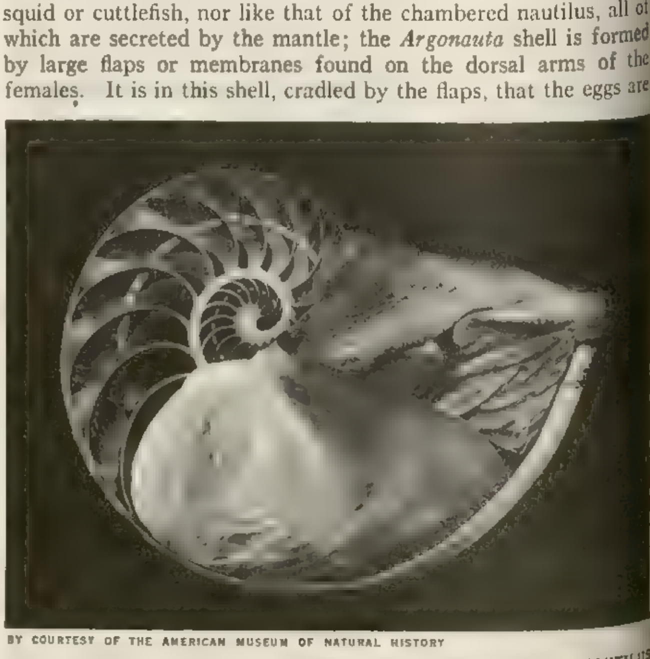
NAUSICAÄ, in Greek legend, daughter of Alcinoüs, king of the Phaeacians in the island of Scheria. When Odysseus (*q.v.*) swam ashore to Scheria, he was found by Nausicaä, who supplied him with clothes and took him to her father's palace, where he was hospitably entertained.

NAUTCH, a dance form of India, literally, any art presentation of song and dance combined. After about 1925 the title was generally applied to the stage presentation of dances of Marwari women who wear and manipulate the wide *gargari* skirt. Spinning turns, the beating of belled feet, coquetry and fluid arm movements are characteristic. (R. M. Hs.)

NAUTILUS, a popular name applied to two distinct genera of cephalopod mollusks: the pearly or chambered nautilus, *Nautilus*, of the southwest Pacific, to which the name properly applies, and the paper nautilus, *Argonauta*, a cosmopolitan genus of open-ocean octopod.

Pearly Nautilus.—Six species of *Nautilus* are recognized, their area of greatest concentration lying between the Fiji and Philippine islands, although dead shells are found on many beaches of the Indo-Pacific region. The animal produces a smooth, coiled shell about 10 in. in diameter, consisting of about 36 chambers, in the last of which it lives. All of the chambers are connected by a tube, or siphuncle, through which gases are secreted into or absorbed from the chambers, in consequence of which the shell acts as a float or hydrostatic organ that aids in ascending and descending through the water. *Nautilus* lives at various depths down to about 2,000 ft., swimming about the bottom in search of shrimp or other creatures upon which it lives. It has up to 94 small, suckerless contractile tentacles that are used for capturing prey. Nautiluses are caught in traps at night when they ascend to shallower waters. In life the shell, sold commercially in many parts of the world, is white with reddish-brown flame markings but when treated and polished is mother-of-pearl. This is the "many-chambered nautilus" of writers. In Polynesia and the Philippines the shells may be cut into fish lures by the natives or worked into cups and vases; in America and Europe they are often fashioned into lamps or other decorative items. The structure and classification of *Nautilus*, the last surviving genus of the ancient order Nautiloidea, are discussed in the article CEPHALOPODA. The nautiloids were extremely numerous in ancient seas, and are important in paleontology for dating the strata in which they occur.

Paper Nautilus.—*Argonauta* is found in all tropical and subtropical seas, living near the surface, although specimens have been captured below 3,000 ft. It feeds upon planktonic Crustacea and other small drifting life. It belongs to the eight-armed order Octopoda but differs from other octopods in possessing a thin unchambered coiled shell not at all like the internal shell of the squid or cuttlefish, nor like that of the chambered nautilus, all of which are secreted by the mantle; the *Argonauta* shell is formed by large flaps or membranes found on the dorsal arms of the females. It is in this shell, cradled by the flaps, that the eggs are



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

SECTION SHOWING INTERNAL FEATURES OF THE PEARLY NAUTILUS (NAUTILUS POMPILIUS)

laid and the young hatch out. Large shells, which attain a diameter of 12 to 16 in., are very fragile and highly prized by collectors. They are often found on the Florida coast. In contrast to the other octopods, the male of *Argonauta* is only about $\frac{1}{10}$ the size of the female, possesses no shell and was once thought to be parasitic in the shell of the female. The argonaut for many years was pictured as sailing about the surface of the seas with the arm flaps extended as sails, until the true function of the flaps was discovered. In all other essentials the female resembles *Octopus*.

NAUVOO, a small historic town in Hancock county in western Illinois, U.S., situated on the Mississippi river about 10 mi. S.W. by S. of Fort Madison, Ia., and 40 mi. N. of Quincy, Ill. The population is about 1,000. Chief industries are wine and *bleu* cheese making. A grape festival held each fall includes the "wedding of wine and cheese," a ceremony brought from Roquefort, France. In Nauvoo is St. Mary's academy, a Roman Catholic boarding school for girls.

Nauvoo's history and significance is especially related to the Mormon era in Illinois history (*see* LATTER-DAY SAINTS, CHURCH OF JESUS CHRIST OF: *Nauvoo*). When the Mormons arrived in 1839 there were already a few buildings in what was called Commerce City; it was renamed Nauvoo by Joseph Smith and grew to be a Mormon community of about 20,000 population.

Following the exodus of the Mormons to Utah in 1846 the town was settled temporarily by a new group, the Icarians, a body of socialists chiefly of French origin; their founder and leader was Étienne Cabet (*q.v.*) of Dijon, France. After purchasing land, Cabet proceeded to establish a communal settlement not unlike other so-called communistic, frontier experiments of the time. At their peak the Icarians at Nauvoo numbered between 1,200 and 1,800. The community was open to anyone who would pay the introductory sum of 300 francs and would donate all his possessions to the community. Men 21 and over and women 18 and over were extended suffrage. A community school was established with separate instruction for boys and girls and a large community dining hall was constructed in the remains of the Mormon temple where all members of the community took their meals. Their economic theories proved unworkable in a frontier situation, however, and the Icarian community was doomed to early failure. A crisis developed when Cabet demanded and was refused dictatorial powers over the settlement. Voted from office, he left Nauvoo with 180 loyal followers and went to St. Louis, Mo., where he died soon after on Nov. 8, 1856. The community never recovered from the split; it soon disbanded and the members were absorbed into the general population.

Evidences of the Mormon and Icarian settlements are still standing, particularly in the area set aside in 1948 as the Nauvoo state park. A number of buildings are maintained as shrines by the Reorganized Church of Latter Day Saints. (G. R. GA.)

NAVAHO, the largest Indian tribe in the United States, numbering close to 90,000 (1960s) according to estimates of the bureau of Indian affairs. Contrary to the notion of the vanishing Indian, their numbers have increased remarkably; in 1868 there were not more than 12,000. The Navaho reservation and government-allotted lands in the states of New Mexico, Arizona and Utah comprise an area roughly the size of New England without Maine. The region, however, is mainly arid and will not support enough agriculture and livestock to provide a livelihood for the tribe. Thousands earn their living as transient workers away from the Navaho country, and appreciable numbers have settled more or less permanently on irrigated lands along the lower Colorado river and in places such as Los Angeles, Calif., and Kansas City, Mo.

The Navaho speak a language closely related to the Apache tongues and more distantly related to other Athapaskan languages spoken in California, Oregon and northwestern Canada (*see* ATHAPASKAN). The ancestors of the Apache and Navaho undoubtedly came from the north and probably did not reach the southwest until A.D. 1000 or later. The Navaho borrowed extensively from the Pueblo Indians: agriculture, weaving, sand paintings and ceremonial traits. Later they acquired livestock from the Spanish through the Pueblos. In the 19th century they learned metalworking from the Mexicans and came to specialize in the silversmithing for which—along with Navaho rugs—they are famous. Painted pottery was never strongly developed and the arts of pottery and basketry have nearly disappeared. The traditional type of house—the hogan—is made of logs plastered with earth and sticks, and always faces to the east. In some localities, hogans are made of stones. Nearby is a sweat house, where male members of the family bathe in ceremonial fashion.

Social Organization.—The Navaho trace descent through the mother, and residence of a newly married couple is most often near that of the bride's mother. The brothers of the mother take certain responsibilities for the upbringing, marriage and property of their sister's children. Traditionally, inheritance was mainly in the mother's line, but this custom is breaking down in the face of the law of the United States and the practices of the English-speaking neighbours of the Navaho. Today children often inherit from both parents.

There are about 60 clans. A Navaho belongs to the clan of his mother but also considers himself related to the clansmen of his father. No Navaho may take a spouse who belongs to the clan of either parent. Indeed the circle of forbidden matings is larger, for some clans are considered as being linked, and marriage into those clans closely associated with the parental group also is forbidden. In modern times clans function largely in the regulation of marriages, although one owes a clan relative hospitality and certain other courtesies. In the past, clan as well as biological relatives could claim part of the property left by a deceased person. Some clans have a particular association with certain ceremonials.

Traditional Navaho society was organized primarily along the lines of kinship. Toward one's relatives on the mother's side and on the father's side and toward one's connections by marriage one had specified obligations according to the kinship category in question. These relatives of course had reciprocal duties. Even the permitted and expected forms of joking between two classes of relatives were prescribed in some detail. The code of behaviour toward those not related either by biology or by clan was an extension of these: "Behave toward everyone as you behave with your relatives."

Religion.—The religious system is intricate. Some of the many myths relate the emergence of the first people from various worlds beneath the surface of the earth; others tell stories which justify the numerous rites that are performed. Some of these are simple rituals carried out by individuals or families for luck in travel, trade and gambling and for protection of crops and herds. The more complex rites demand a specialist who is paid according to his skill and the length of the ceremonial. One type of specialist is the diagnostician, who carries out one of various forms of divination to determine what is required. Most rites are primarily for the purpose of curing bodily and psychiatric illness. Ordinarily, ill-health is held to have a supernatural cause, such as the violation of a tabu (*q.v.*) or the malevolent activity of ghosts or witches. The patient is purified by emetics and sweating, fed herbal medicines, sung and prayed over, placed upon a sand painting. In other ceremonies there are simply prayers or songs, and dry paintings may be made of pollen and flower petals—rather than of minerals upon a background of sand. In some cases there are public dances and exhibitions at which hundreds or thousands of Navaho gather.

Tourists often attend these, especially the squaw dance which is frequently held during the summer months. This "girl's dance and sway-singing" (as the Navaho call it) is a feature of an ancient war ceremonial held to cure men who had been made sick by the ghosts of slain enemies. In modern times it serves as a marriage mart where young people meet each other and parents and other relatives can discuss the economic arrangements for projected alliances. More solemn are the night chants and mountain chants, held in the autumn months "after the thunder sleeps." The former concludes with all-night singing and dancing by masked impersonators of the divinities, and the latter with the famous fire dance in which the almost naked participants jump through flames and chase each other with burning brands.

Arts.—There are hundreds of Navaho silversmiths, principally men. For most of them silversmithing is a part-time occupation, but some are full-time professionals, either self-employed or working for stores both on and off the reservation. They make bracelets, necklaces, rings and other kinds of jewelry. Turquoise and, to a lesser extent, coral and various stones are used as settings. Silver pieces are both hammered and cast. Increasingly in modern times tableware, cigarette boxes and other articles are made for sale to others. First American and later Mexican coins were the source of the silver; now it is supplied by traders. The Navaho—mostly the women—have practised the art of weaving wool since at least 1706. The earliest surviving specimens date from the first years of the 19th century. The so-called classical period, which attracts most collectors, dates from the late 1840s to about 1875. The blankets, poncho blankets and women's dresses from this period exhibit both technical excellence and great beauty of design. While hand-spun yarns continued to be used as weft elements in coarser utility articles, ravelings of a red cloth, imported from England and called in Spanish bayeta, were prominent in loom goods intended as body coverings. Bayeta provided a shade of red brighter than could be obtained from the native dyes then available. Three-ply yarns (Saxony and zephyr) of European manufacture were also introduced by some traders.

After the mid-1870s the importation of bayeta and other foreign yarns declined. Four-ply yarns (Germantown type) made in the United States were often substituted. At about the same time the increase in the availability of manufactured clothing and other textiles brought about a gradual shift in the type of articles woven. Since 1890 the Navaho have woven only saddle blankets and women's sashes for their own use, concentrating the bulk of their production on floor coverings purchased by others. These rugs are of varying quality and aesthetic appeal. Commercial dyes of garish colour have frequently been employed, and outlandish designs (railroad trains, flags, masonic emblems and the like) have sometimes been woven. On the other hand, many rugs of the 20th century have been produced in the natural colours of white, black, brown and gray or in the soft tones derived from vegetable dyes. A small number of rugs reproducing sand paintings have been woven, often by the few Navaho men who weave. In the past almost all Navaho women knew how to spin, card and weave, and most of them produced rugs, at least occasionally.

The Navaho Today.—In spite of the activities of missionaries and of U.S. government officials, Navaho religion and social behaviour remained—except in areas immediately adjacent to the railroad and the highway—little altered until about the time of World War II, when several thousand tribesmen entered the armed services and thousands more worked in defense industries. The period after 1946 was one of vast change. Many Navaho moved into more modern cabins and began to dress much like their non-Indian rural neighbours. The level of literacy and of competence in English greatly rose. By the 1960s, the vast majority of children of school age were receiving instruction, as opposed to a minority in earlier years; about 27,000 Navaho from the ages of 6 to 18 were in school; well over 90% of this age group. The tribal council, using funds accruing from gas, oil and mineral royalties, was providing loans and scholarships for hundreds of young people to attend college or pursue other forms of advanced training. Approximately 300 Navaho were attending institutions of learning beyond the high school level. The council was vigorous in building roads and motels to attract tourist income, and in inviting small industries to locate on or near the reservation.

The income of the tribe from oil and gas leases and royalties was about $1,500,000 per year. In the same period tribal income from other minerals came to about $500,000 per year, with other substantial increments from timber and other tribal properties. In addition, the tribe has received sizable lease bonuses—about $5,700,000 per year since 1950. The tribal budget has exceeded the yearly sum of $14,000,000, of which about half was allocated to capital investments. The remainder was assigned to such categories as community services, legal and judiciary, management of minerals and range lands and operations of the tribal council.

There remained many serious problems for the tribe. Per capita income was low. About 1,600 Navaho were the recipients of public financial assistance per year. Of those relocated off the reservation nearly 40% had returned; yet the reservation could not support steadily increasing numbers. Young people who received training beyond high school found it difficult to obtain positions with salaries appropriate to their skills.

Death rates were still very high; of major causes of death only those for heart disease and malignant growths were appreciably lower than for the United States as a whole. Tuberculosis and certain diseases of the intestinal tract were nine times as great and accidents and various diseases of early infancy twice as great as the U.S. average.

NAVAL ACADEMY, UNITED STATES: *see* MILITARY, NAVAL AND AIR ACADEMIES.

NAVAL AFFAIRS (ARTICLES ON). The survey article SEA POWER analyzes the nature of the influence that navies and naval bases have exerted on the course of history. The roles of the various components of a navy in contesting control of the sea lanes and in serving as mobile bases for guns, rockets and aircraft are summarized in FLEET, NAVAL. Individual types of warships are described, and their historical backgrounds and contemporary roles discussed, in a series of articles that includes AIRCRAFT CARRIER; BATTLESHIP; CORVETTE; CRUISER; DESTROYER; FIRESHIP; FRIGATE; MONITOR, NAVAL; and SUBMARINE. Navies of antiquity and the strategic plans around which they were built are discussed in NAVIES, EARLY HISTORY OF.

Articles on naval installations include DOCKYARDS AND NAVAL BASES; and BUNKERING, SHIP. The training of naval officers is treated in MILITARY, NAVAL AND AIR ACADEMIES. OFFICERS, MILITARY, pertains in part to the naval service.

Various shipboard activities in war and peace are covered in such articles as GUNNERY, NAVAL; NAVIGATION; RULES OF THE ROAD AT SEA; SEAMANSHIP; and SIGNAL COMMUNICATION, MILITARY. Articles on equipment include ARMOUR, NAVAL; BUOY; ECHO SOUNDER; LOG, MARITIME; MINE, NAVAL; PARAVANE; RADAR; RADIO; TORPEDO; etc.

Specialized phases of naval warfare, in addition to those mentioned above are described in BLOCKADE; COAST DEFENSE; and CONVOY. Articles devoted to special branches of naval service include COAST GUARD; MARINES.

Many articles deal in whole or in part with the relationship between sea power and international relations. These articles include ANGARY, RIGHT OF; CONTRABAND; EMBARGO; MARE CLAUSUM AND MARE LIBERUM; NORTH ATLANTIC TREATY ORGANIZATION; PARIS, DECLARATION OF; PRIZE COURTS AND PRIZE LAW; STRAITS AND INTEROCEANIC CANALS; STRAITS QUESTION; VISIT AND SEARCH; WATERS, TERRITORIAL; etc. Additional listings are given under INTERNATIONAL RELATIONS (ARTICLES ON).

Articles on wars and major campaigns that contain sections on naval warfare include AMERICAN CIVIL WAR; AMERICAN REVOLUTION; DARDANELLES CAMPAIGN; DUTCH WARS; FRENCH REVOLUTIONARY WARS; NAPOLEONIC WARS; SEVEN YEARS' WAR; etc. Additional articles are devoted to great naval battles; *e.g.*, ARMADA; COPENHAGEN: *Battle of Copenhagen;* CORONEL, BATTLE OF; FALKLAND ISLANDS, BATTLE OF THE; FIRST OF JUNE; JUTLAND, BATTLE OF; "MONITOR" AND "MERRIMACK," BATTLE OF; NAVARINO, BATTLE OF; NILE, BATTLE OF THE; QUIBERON BAY, BATTLE OF; SAINTS, BATTLE OF THE; SAINT VINCENT, BATTLE OF; TOULON: *History;* TRAFALGAR, BATTLE OF; YORKTOWN.

Further information on the historic encounters of individual navies and on their contemporary status will be found in history and defense sections in articles on nations; *e.g.*, FRANCE; GERMANY; GREAT BRITAIN AND NORTHERN IRELAND, UNITED KINGDOM OF; UNITED STATES (OF AMERICA).

Questions of administration and personnel are dealt with under ADMIRAL; ADMIRALTY; INSIGNIA, MILITARY; MEDICAL SERVICES, MILITARY; MIDSHIPMAN; etc.

Articles on related topics include those listed under MILITARY AFFAIRS (ARTICLES ON); also, such articles as BOAT; SEAPLANE; SHIP; and SHIPBUILDING.

Biographical articles summarize the careers of the great naval strategists and tacticians such as DAVID BEATTY, GEORGE DEWEY, SIR JOHN HAWKINS, JOHN PAUL JONES, ALFRED THAYER MAHAN, and HORATIO NELSON.

Wherever comprehensive information on a topic is desired, the Index should be consulted for an inventory of material connected with it.

NAVAL ARCHITECTURE is the art and science of designing boats and ships to perform the missions and to meet the requirements laid down by the prospective owners and operators. It involves knowledge of mechanics, hydrostatics, hydrodynamics, steady and unsteady body motion, strength of materials and design of structures. A good naval architect and ship designer must have experience in a number of fields of engineering. He must also understand the characteristics and properties of construction materials and be familiar with the latest and best methods of fabricating parts and joining them. Like other branches of engineering, naval architecture involves estimates and predictions of the final performance of the ship and all its parts. Such calculations must be made while the ship is still in the paper stage in the form of plans and specifications.

This article is divided into the following sections:

- I. The Mission of a Ship
- II. Weight and Buoyancy
  1. Hydrostatic Forces
  2. Calculation of Ship Weight and Buoyancy Volume
  3. Achieving Level Attitude or Trim
- III. Metacentric Stability

I. THE MISSION OF A SHIP

The detail requirements for any given ship are made up on the basis of its mission. Just how much cargo and how many passengers is it to carry? What are the limitations on draft in the harbours it must enter? What is to be its maximum or sustained speed, and under just what conditions? What must be its cruising radius, in terms of days as well as of distance? For a tug, the towing pull or free-running speed must be stated. For an icebreaker, capacity to push its way through ice of a specified thickness must be shown. For a warship, the armament must be given, and the boundaries to be protected by armour must be specified.

The wide variety of missions for watercraft produces a great number of distinct and specialized types. Considering naval architecture and design, these are subdivided roughly into two main classes, warships and merchant ships. But the distinction is not always a sharp one. A naval transport may closely resemble a merchant passenger ship, and may be designed in the same way. A fast motor cruiser may be designed like a PT boat without torpedoes, guns and depth charges. In fact, the navy of any nation includes many merchant types, among them store and supply ships, oilers, ammunition- and missile-supply ships, repair ships, tenders for small craft, hospital ships and personnel transports.

II. WEIGHT AND BUOYANCY

1. Hydrostatic Forces.—A ship floating at rest in calm water is acted upon by two gravity forces, weight and buoyancy. Weight is the downward force on the ship. The total weight force (W) acts on the ship as if it were concentrated at the balancing point or the centre of gravity (G). Buoyancy is the upward force of all the hydrostatic pressures on the hull. The horizontal com-

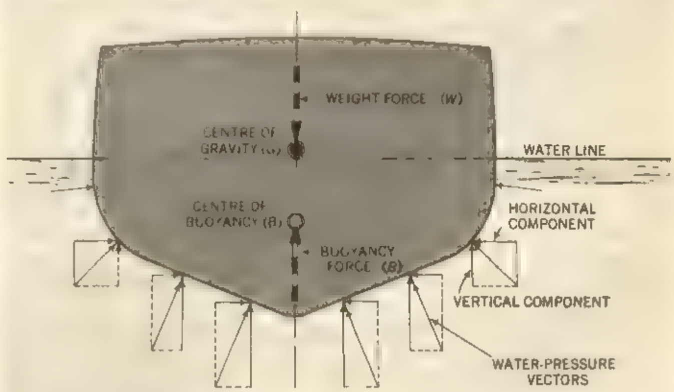

FIG. 1.—FORCES ACTING ON A SHIP HULL AT REST IN CALM WATER

ponents of the water pressures on unit areas of the ship's sides and bottom, increasing with depth, act in opposite directions and cancel each other (fig. 1). The vertical components of the water pressures on unit areas combine to form an upward force (B) equal to the weight of the water displaced by the underwater hull volume. This weight varies slightly with the specific gravity of the water. The centre of buoyancy (B) lies at the geometric centre of the immersed volume. The ship sinks in the water until the force B exactly equals the force W.

2. Calculation of Ship Weight and Buoyancy Volume.—In an early stage of the design, the ship weight is estimated as the sum of the weights of the cargo, hull, fittings, equipment, propelling and auxiliary machinery, piping systems, electrical and electronic gear, fuel, water, consumable stores, passengers and crew, plus a margin of a few per cent for weights that are underestimated. At a later stage the weights are calculated more precisely,

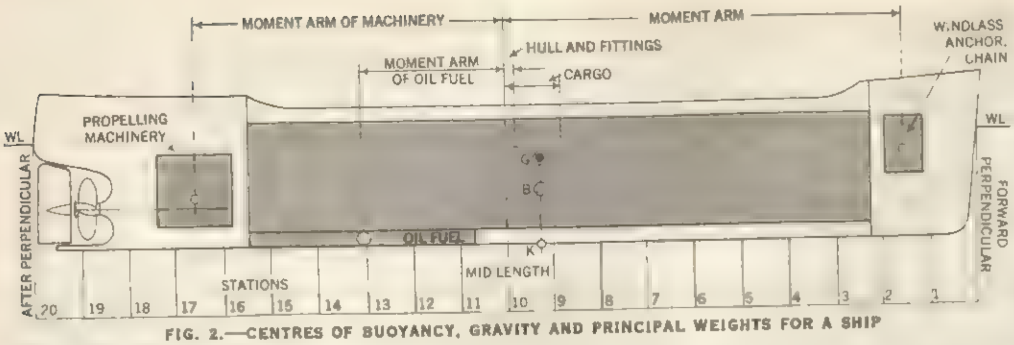

FIG. 2.—CENTRES OF BUOYANCY, GRAVITY AND PRINCIPAL WEIGHTS FOR A SHIP

submarine, W and B must equal each other exactly. It is also important to ensure that, when submerged, the centres G and B are in the same transverse plane so that the craft floats level when stopped under water (fig. 3).

The weights and weight moments for a submarine are estimated and calculated exactly as for a surface ship, but two separate volumes must be calculated one for the surface condition, with main-ballast tanks empty and one for the submerged condition, involving principally the volume of the pressureproof hull. To the volume of the latter there must be added the water-excluding volumes of all parts external to it. Among these are the outer hull structure, shafting, propellers, rudders and diving planes, anchors and chains, masts and periscopes, and the great multitude of external items. For every seven tons of solid steel in this category, about one ton of buoyancy force is gained.

or are taken from actual weights of similar items. In many cases, the weight estimates are revised constantly as the design proceeds to avoid an ultimate overweight that might detract seriously from the ship's performance.

The underwater volume of the ship under design must be adequate not only to displace a weight of water that will support the entire ship, but it must be so disposed in length, breadth and height and so shaped in every part that all the other operating and naval architectural requirements are fulfilled. When the ship is built and fully laden it must float level and upright at the designed water line (fig. 2).

As the naval architect fashions the underwater and above-water portions of the hull and maintains a running check of the estimated weights and calculated buoyancy volumes, he also keeps track of the products of these weights and volumes times the horizontal fore-and-aft distances or "moment arms" of each from the transverse vertical reference plane at mid-length. These products are known as the longitudinal weight and buoyancy moments.

To carry out these operations systematically, the underwater hull is divided into segments by imaginary transverse planes called stations. There may be 10 such segments for a boat, 40 or more for a large ship. The volume of each segment is computed together with the position of the centre of volume for each. The forward and after moments of volume are then computed in the same way as for the fore-and-aft moments of weight. A summation of the individual segment volumes gives the total underwater hull volume. The fore-and-aft positions of the centres of gravity of the individual weight groups are then estimated. Separate sums are kept of the moments of these groups forward of and abaft the mid-length. Dividing the total underwater hull volume by the volume per unit weight of the fresh, brackish or salt water in which the ship is to run gives the weight of water displaced. This must equal the total weight if the ship is to float at the designed water line. The net weight moment, forward of or abaft mid-length, is divided by the total weight to give the distance at which the centre of gravity (G) lies forward of or abaft the mid-length. The same operation for the volume moments gives the fore-and-aft position of the centre of buoyancy (B).

3. Achieving Level Attitude or Trim.—For the ship to float at the level attitude or zero trim desired, G and B must lie in the same vertical transverse plane (fig. 2). If their calculated positions are different, and the size, proportions and shape of the underwater hull are satisfactory, it is customary to shift the weights within the hull until the desired trim is attained.

In practice, the record of estimated weights and fore-and-aft moments is accompanied by a record of vertical moments above the keel (K) or the base plane. From this it is possible to estimate the position of G above K. At the same time, a record is made of vertical moments of buoyancy. When summed up and divided by the volume, these give the position of B above the keel. Both the distances $\overline{KG}$ and $\overline{KB}$ are required for estimating the metacentric stability, discussed below.

If, when the ship is built, the actual weights and volumes, or their centres, do not agree exactly with the estimated values (some equipment may have been added during the construction period), the ship floats at a water line slightly different from that contemplated by the operator and designer. For a surface ship this difference is usually of no great importance. However, for a

III. METACENTRIC STABILITY

1. Concept of the Metacentre.—One would think, at first sight, that the average surface ship of fig. 1, with its weight concentrated above its point of support (considered as the centre of buoyancy), would fall over like a top that has stopped spinning. But if properly designed it does not do so, because as the ship is inclined transversely, say by a strong wind, the centre of buoyancy of the immersed portion of the hull shifts sideways, in the same direction as the inclination. This is because the volume of the wedge of emersion (fig. 4) shifts to the low side, in the position indicated for the wedge of immersion. At the new inclined water line (W_1L_1) the centre of buoyancy moves from B to B_1. The total buoyancy force continues to act upward along the true vertical, now in the direction of B_1M. Provided no weights shift as the ship inclines, the centre of gravity remains at G, in the keel-to-deck centreline. The buoyancy force acting upward along B_1M and the weight force acting downward through G produce a righting moment $W(\overline{GZ})$ which acts to return the ship to its upright position.

For small angles of inclination ϕ, say less than 10°, the verticals through the shifted centres of buoyancy intersect the ship centreline at or close to a point M, called the metacentre. The stability provided by the action described is therefore called metacentric stability. For the situation diagramed in fig. 4, the one most often encountered in practice, it is transverse metacentric stability. For a similar situation in which the ship is inclined or

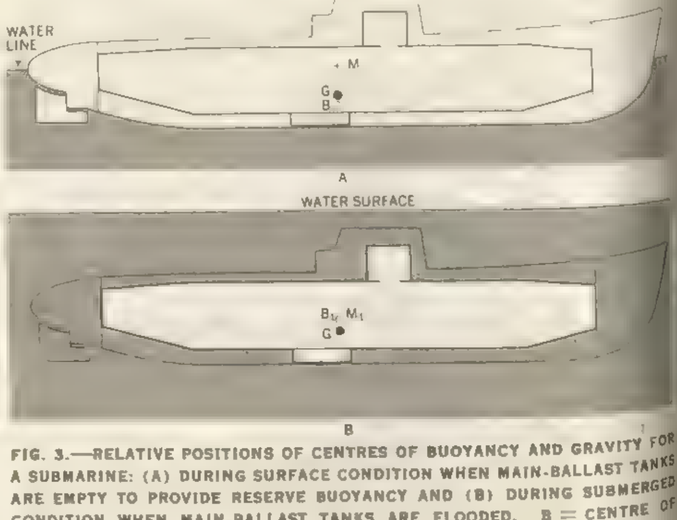

FIG. 3.—RELATIVE POSITIONS OF CENTRES OF BUOYANCY AND GRAVITY FOR A SUBMARINE: (A) DURING SURFACE CONDITION WHEN MAIN-BALLAST TANKS ARE EMPTY TO PROVIDE RESERVE BUOYANCY AND (B) DURING SUBMERGED CONDITION WHEN MAIN-BALLAST TANKS ARE FLOODED. B = CENTRE OF BUOYANCY OF THE OUTER HULL; B_1 = CENTRE OF BUOYANCY OF PRESSUREPROOF HULL; M = METACENTRE

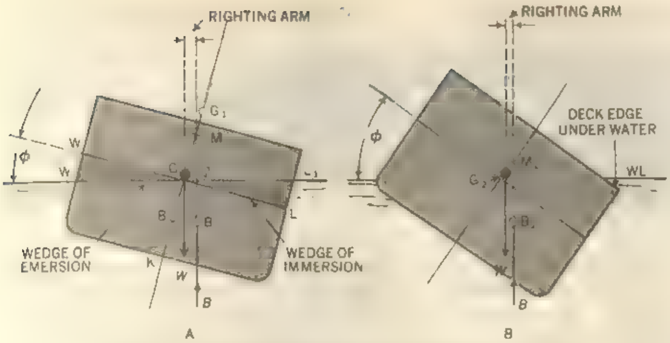

FIG. 4.—FORCES ACTING ON A SHIP WHEN HEELED

trimmed in its fore-and-aft centre plane, it is longitudinal metacentric stability.

If the centre of gravity of the ship is too high, as at G_1 in fig. 4, the righting moment for any inclination is negative; that is, it acts to incline the ship still further. The ship then has transverse metacentric instability. Whether it will capsize or not depends upon whether the position G_1 is overtaken by the vertical through B_1 as the inclination increases. If so, the ship remains in that inclined position, with a righting moment that is practically zero.

2. Indexes of Metacentric Stability.—The distance $\overline{GM}$ for positive stability, known as the metacentric height, is taken as one index of the degree of metacentric stability. The other is the range of stability, or the angle of inclination at which the metacentric height diminishes to zero. For example, when a ship is heeled transversely until the depressed deck edge goes under water (fig. 4[B]), the centre of buoyancy B_2 cannot move to the inclined side far enough to keep the metacentre M_2 well above the centre of gravity G_2 on the ship centre plane. At a critical inclination the metacentre lies at the centre of gravity and the righting moment disappears. For inclinations beyond this the metacentric height becomes negative, the righting moment becomes a capsizing moment and the ship rolls over.

A greater range of metacentric stability is built into a ship by raising the uppermost watertight deck to a higher position above the calm-water plane of flotation. The ship can then heel to a greater angle before water comes over the lower deck edge. For a craft like a sailing yacht, with a deep, heavy stabilizing keel, the deck edge can actually go under water and the range of positive stability can extend to large angles, provided water is kept out of the hull as the water level climbs higher and higher over the inclined deck.

The desirable value of transverse $\overline{GM}$ varies with the type, size and service of the ship, but within limits it is still subject to the experience and judgment of the naval architect. It averages from 0.04 to 0.06 of the beam but may be as high as 0.10 of the beam for combatant vessels subject to heavy damage. For fishing vessels it may have two values, one for the outgoing and one for the return or loaded part of the voyage. The range of positive transverse $\overline{GM}$ for a normal ship to run in the open sea is usually in excess of 40° and may run as high as 70° or more, provided the hull remains intact and the weights do not shift.

3. Vertical Position of Metacentre.—The height of the metacentre above the keel, or other selected point, depends upon the shape and size of the underwater body and of the at-rest water line. The total height $\overline{KM}$ (fig. 4) is the sum of the height $\overline{KB}$ of the centre of buoyancy above the keel and the height $\overline{BM}$ of the metacentre above the centre of buoyancy. The latter is known as the metacentric radius. The distance $\overline{KB}$ can be estimated by an approximate formula; it can be calculated by procedures applying to irregular volumes; or it can be determined by a mechanical integrator. The distance $\overline{BM}$ is the quotient of I divided by V, where I is the square moment of area of the water line plane from W to L (the sum of each unit of area multiplied by the square of its distance from the centreline) and V is the immersed volume. For a given ship length and underwater volume, both I and $\overline{BM}$ are proportional to the cube of the beam, so that the latter is an important factor in transverse metacentric stability.

4. Vertical Position of Centre of Gravity.—The vertical position of the centre of gravity is as important as that of the metacentre in determining metacentric stability and the behaviour of the ship at sea. For a cargo ship, or even for a warship, this position may change by many feet, depending upon the nature, amount and vertical position of the loads, fuel and stores. Ballast may be used to increase the total moving mass in a seaway or to place G in a more advantageous position. Ice accumulating on the upper works of fishing boats, trawlers and other small craft may be so thick, so heavy and so high above the normal centre of gravity, as well as so difficult to remove at sea, that G rises above M and the craft capsizes.

5. Inclining Experiment.—Fortunately, the naval architect is able to make a full-scale check of the predicted or calculated metacentric stability before the completed ship goes to sea. By shifting liquids or solid masses whose weights and offset positions are known accurately, the centre of gravity of the whole ship is shifted and the ship is heeled. This shift, corresponding to the distance $\overline{GZ}$ in fig. 4, is sideways for a determination of transverse $\overline{GM}$ and lengthwise for a measurement of longitudinal $\overline{GM}$. The angle of inclination ϕ of the ship for each such shift is measured accurately with special devices. Then from the relation $\overline{GZ} = \overline{GM} \sin \phi$, the actual metacentric height $\overline{GM}$ is determined for that loading condition. The height of the centre of gravity above the keel is then calculated from the relation $\overline{KG} = \overline{KB} + \overline{BM} - \overline{GM}$.

6. Stability of Submarines.—When a submarine is in surface condition its metacentric stability situation is the same as that of any surface ship. When diving or submerging its water-plane area diminishes progressively to a negligible amount. The square moment of area I_T of this plane likewise diminishes and with it the value of $\overline{BM}$. Moreover, as the main-ballast tanks are flooded and the pressure hull is taken under, buoyancy is transferred from a low to a high position, so B rises in relation to the hull. Since G remains in its original position, M drops to the vicinity of G. Indeed, for some moments during diving and surfacing it may be below G, with a negative $\overline{GM}$. The flooding, venting and blowing of the main-ballast tanks, with separate port and starboard controls, enable the submarine crew to counteract any list that may develop during this brief transition period.

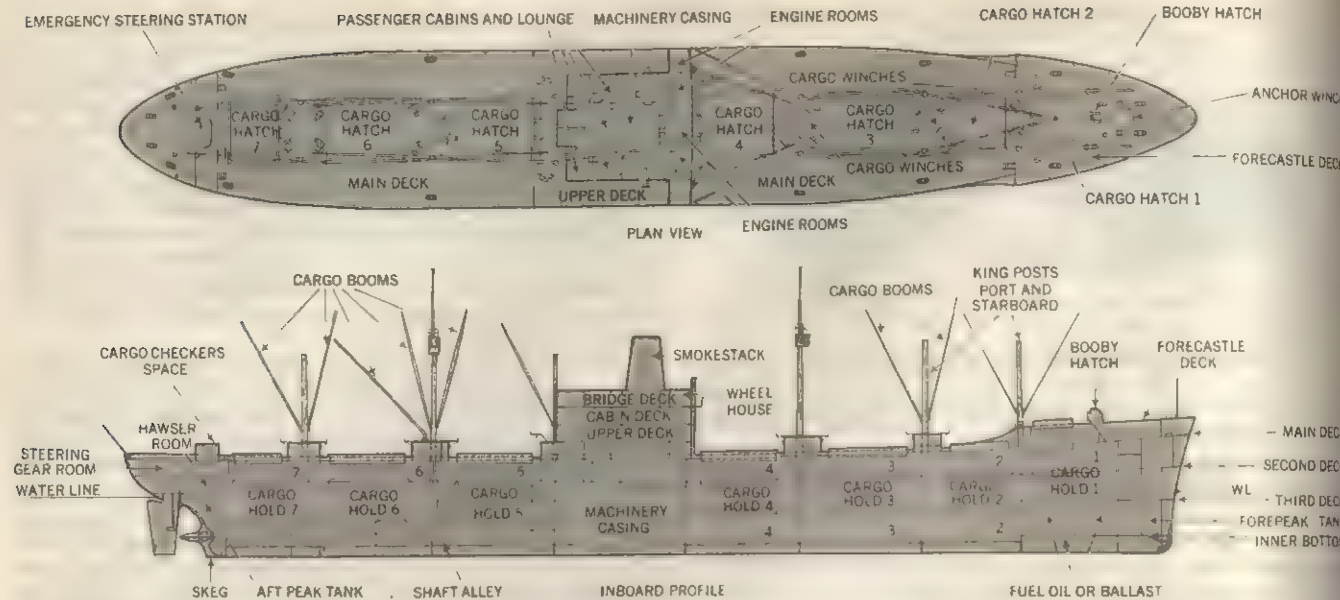
When the submarine is under the surface the water-plane area is zero, as is $\overline{BM}$. This means that B_1 and M coincide (fig. 3). In this condition B_1 is higher than G, so that the action of the buoyancy force and the weight force produces a stable situation and the craft is said to have pendulum stability. $\overline{B_1G}$ (or $\overline{GM}_1$) then replaces $\overline{GM}$ as the criterion of both transverse and longitudinal stability.

IV. ARRANGEMENT

Despite the many ships of each type that have been designed over the years and the general similarity of various spaces and their locations within the types, ship operators still find advantages in particular arrangements. This situation reveals the variety of combinations possible when the designer endeavours to make large-scale compromises with both major and minor features. Propelling machinery at the stern with crew accommodations and navigating spaces in one group aft over the machinery represents efforts to devote the most useful spaces to the cargo and to concentrate services and living spaces in a region clear of cargo-stowing and cargo-handling areas. Naval architectural requirements impose limitations concerning weight distribution, metacentric stability, hull strength and stiffness, and subdivision and damage control which can rarely be disregarded.

1. General Arrangement Features by Ship Type.—A brief tabulation of principal ship types serves to highlight the arrangement features characteristic of each.

Passenger liners for ocean crossings, carrying only passengers, baggage and incidental cargo, devote large volumes in the most comfortable part of the ship to passenger accommodations, with large additional volumes for public spaces in deckhouses and superstructures. The propelling machinery, uptakes and hatches are placed clear of the accommodations.



BY COURTESY OF U.S. NAVY

FIG. 5.—PLAN OF WEATHER DECKS AND INBOARD PROFILE OF A "MARINER" CLASS CARGO SHIP

Passenger ships for service on rivers and in protected waters utilize deck and superstructure volume as passenger spaces for practically the entire length. Excursion ships for day service extend the accommodations to overhangs beyond the main hull.

Combined passenger and cargo ships devote the most comfortable positions to the passengers without encroaching unduly on storage and handling facilities for cargo.

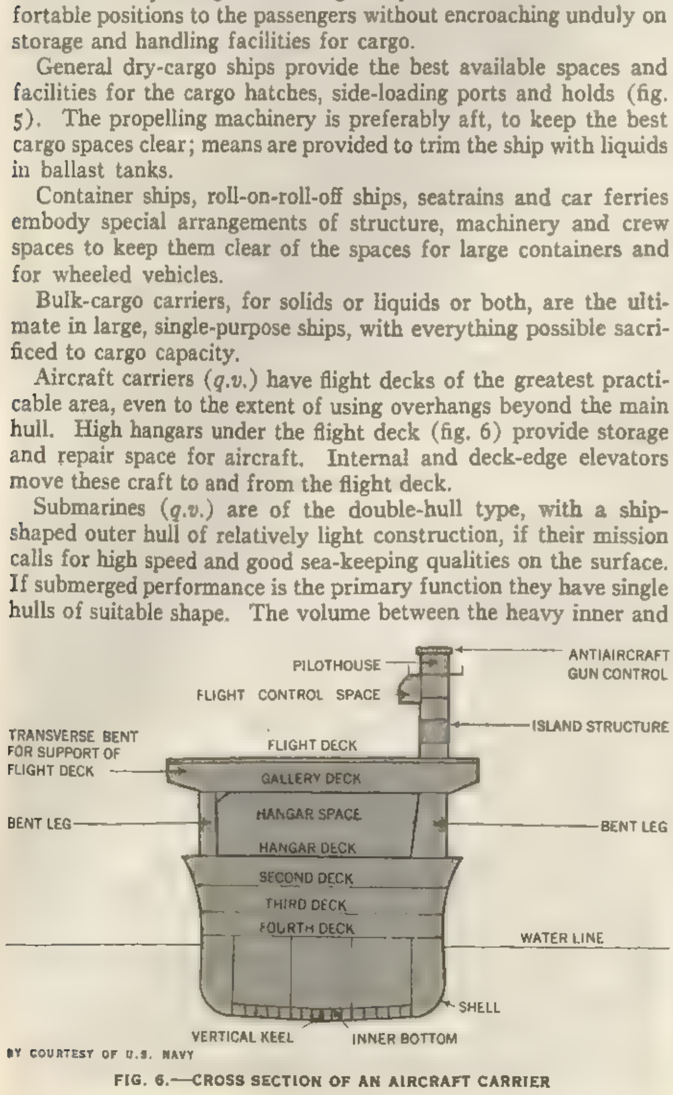
General dry-cargo ships provide the best available spaces and facilities for the cargo hatches, side-loading ports and holds (fig. 5). The propelling machinery is preferably aft, to keep the best cargo spaces clear; means are provided to trim the ship with liquids in ballast tanks.

Container ships, roll-on-roll-off ships, seatrains and car ferries embody special arrangements of structure, machinery and crew spaces to keep them clear of the spaces for large containers and for wheeled vehicles.

Bulk-cargo carriers, for solids or liquids or both, are the ultimate in large, single-purpose ships, with everything possible sacrificed to cargo capacity.

Aircraft carriers (*q.v.*) have flight decks of the greatest practicable area, even to the extent of using overhangs beyond the main hull. High hangars under the flight deck (fig. 6) provide storage and repair space for aircraft. Internal and deck-edge elevators move these craft to and from the flight deck.

Submarines (*q.v.*) are of the double-hull type, with a ship-shaped outer hull of relatively light construction, if their mission calls for high speed and good sea-keeping qualities on the surface. If submerged performance is the primary function they have single hulls of suitable shape. The volume between the heavy inner and light outer hulls of a double-hull craft is devoted to carrying fuel and ballast liquids which need not be protected from hydrostatic pressure.



BY COURTESY OF U.S. NAVY

FIG. 6.—CROSS SECTION OF AN AIRCRAFT CARRIER

Underwater cargo vessels or submersible bulk carriers also require some of their bulk volume devoted to main-ballast tanks, by the blowing of which the craft may be lifted with its deck above water and with its bottom high enough to clear the beds of estuaries and harbours. (*See* also SHIP.)

2. Cargo Handling.—The ship arrangement must lend itself to getting the cargo and other objects in and out as well as to carrying them from one port to another. Indeed, speed in loading and unloading cargo is just as important as speed through the water. Access to the holds and to the internal deck spaces is provided by hatches through the decks and by doors in the ship's side leading to the deck storage areas.

Ships carrying dry general cargo usually are equipped with their own handling gear. This enables them to transfer cargo in any port and to load to and from lighters in places where they must anchor offshore. Some bulk-cargo ships carry a huge swinging boom with a belt conveyer running on it, by which material may be dumped in high piles at a distance from the ship's side. Freight cars are loaded and unloaded from seatrains by special dock cranes that pick up an entire loaded car. Liquid cargo is pumped aboard through flexible pipes from storage tanks on shore; the unloading is invariably done by the ship's own high-capacity pumps.

3. Watertight Closures.—Whatever the mission of a craft, or the arrangement of major and minor features adopted, water must definitely be excluded from the hull under severe operating conditions. This calls for strong, tight closures for openings, including doors, port covers and protectors for glass windows. It also requires the watertight and wave-resistant sealing of large openings such as cargo hatches. On many ships these openings are closed by heavy metal covers handled by mechanical power and capable of secure sealing and locking. The structure surrounding these openings must be so rigid that its deformation under wave or sea loads or other service conditions does not jeopardize the watertightness of the cover.

4. Ballast Tanks.—When a ship is running rather light with its hull relatively high out of water, it is at a disadvantage in winds and waves. It needs added inertia to help it drive through waves, added weight to put the hull farther down in the water and more mass high in the ship to reduce the righting moment and to ease the rolling. These needs are met by building in tanks that can be filled with fresh water or reserve fuel. The tanks are easily emptied when the weight is no longer desired. Awkward and inaccessible places in the hull, where neither cargo, machinery nor useful load can be placed to advantage, can often be used for these tanks

All submarines, whether they have two separate hulls or not, carry main-ballast tanks. These are empty when the craft is on the surface; they help to lift the bridge, the deck and the hatches above the water and to provide reserve-buoyancy volume when rolling and pitching in waves. By opening flood valves at the bottom and air-vent valves at the top, these tanks may be completely flooded with sea water to make the craft submerge. To raise the submarine, the vent valves are closed and the water is blown out by compressed air. Another set of tanks, called the variable-ballast tanks, have water taken into or pumped out of them from time to time to keep the weight of the submarine always equal to the weight of the water displaced by the buoyant volume. When a submarine runs from salt water into brackish water having less weight per unit volume, some water must be pumped out of the variable-ballast tanks because the supporting forces are less in the lighter water.

V. RESISTANCE AND PROPULSION

The resistance to forward motion of a ship is of three principal kinds: friction; wave making; and separation or eddy making. Friction or viscous resistance is caused by the necessity for accelerating liquid particles in a forward direction as the bow continually runs into a region of liquid at rest. The layer of accelerated particles, augmented by vortex motion and turbulence, becomes progressively thicker as it moves aft, forming what is known as the boundary layer. The vortexes and disturbances in this layer are visible in the belt of "confused" water around a moving ship at the water line. The energy in this layer represents the work done by the ship in overcoming viscous resistance. It is eventually dissipated as heat and is not recovered.

Wave-making resistance is caused by transferring kinetic energy in the ship to energy in the surface or gravity wave system which accompanies it. While the configuration of this system near the ship remains fixed for a given speed, waves are continually left astern and the energy in them is lost.

Separation is caused by the lack of sufficient pressure in the water (see *Separation Resistance*, below) in a given region to force this water laterally inward and to make it flow closely along all parts of the ship, especially in the tapering or blunt after portion. In the region known as the separation zone, water is dragged in from astern to fill the gap that would be left because the flow does not close in from the sides. Resistance is generated by the forward acceleration of water that would otherwise flow aft and be left behind. The confused and eddying mass of water being dragged along in the separation zone abaft the square transom stern of a motorboat is clearly visible at low and moderate speeds. The added drag due to separation abaft the square stern of a skiff, immersed deeply by passengers sitting in the stern, is very real to the rower in that skiff.

1. Computing Friction Resistance.—For want of a better or more precise method, the friction resistance of a ship is computed from a knowledge of its wetted area and a friction value per unit area derived from the towing of flat planks or friction planes of various lengths at various speeds. By using very thin sections, sharply pointed at the ends, wave making and eddy making are eliminated. From the known towing forces and wetted area of the plank or plane there are derived a set of friction values per unit surface area of the plane, in terms of the towing speed. For calculating the friction resistance of a ship at any given speed, it is usually assumed that the friction value for each unit of wetted-surface area is equal to that for a friction plane having the same length as the ship and towed at ship speed. The wetted area of the ship is calculated by averaging the girth at a series of stations equally spaced along the length and multiplying by the wetted length. The flat-plate friction data cannot be applied indiscriminately to the curved surfaces of ships. Effects of given curvatures are not well known but it is assumed that the friction resistance increases as the curvature becomes sharper.

Rough areas on wetted ship surfaces are caused by uneven plating and planking; laps, butts, rivet points and weld beads; anticorrosive and antifouling coatings of plastic paint and other materials; and fouling due to marine organisms. All of them increase friction resistance and the thickness of the boundary layer. For resistance calculations their effects are lumped in a general roughness allowance, which is added to the value of the friction for a given area of smooth surface.

2. Wave-making Resistance.—Information available to the naval architect on the surface waves generated by a moving ship is derived originally from the observations of John Scott Russell in the 1840s, the experimental work of W. Froude and R. E. Froude in the 1870s and 1880s and the analytic studies of Lord Kelvin in the latter decade. These showed that: (1) A gravity wave system is formed by a moving pressure disturbance. For example, drawing one's finger across a water surface makes waves. (2) Pressure disturbances exist where there are changes in curvature around a ship, such as those at the extreme bow and stern and at the "shoulders." (3) The progressive or traveling wave system caused by each pressure disturbance consists of two parts: (*a*) a diverging group of waves, with crests and troughs lying at a small angle to the direction of motion of the disturbance, and (*b*) a transverse group of waves, with crest lines slightly convex forward, where they cross the path of the moving disturbance. The diverging waves at the bow are easily seen on any moving boat or ship, as are the transverse waves abaft the stern on any craft which is traveling rapidly. The transverse waves of the bow system, modified by the forward shoulder system, are also indicated by the crests and troughs in the wave profile alongside the ship.

In addition to the progressive waves, whose shape remains the same for a given speed but which spread outward and aft, there is a water-level disturbance that moves along with the ship and whose elevations at the bow and stern and depression amidships are not radiated as gravity waves. There may thus be six or eight or more sets of water-level changes generated by the movement of one ship. The changes of elevation due to each are superposed so that two crests coinciding produce a sort of double crest, while a crest and a trough coinciding act to cancel each other.

From a resistance standpoint the most important progressive wave systems are generated at the bow and stern. The length of a gravity wave depends upon its velocity, and the velocity of a wave whose crest travels along with the bow must correspond to the ship speed. It follows, therefore, that the second, third and succeeding crests of the transverse bow series move aft along the ship as the speed increases. This means that at certain ship speeds a transverse crest of the bow system is superposed on the stern system in such manner as to build up a traveling mound of water at the stern. The internal hydrostatic pressure in this mound acts to push the ship forward and hence to diminish its wave-making resistance.

At other ship speeds the superposition of the bow and stern wave systems drops the water level at the stern, with no compensation for the hydrostatic pressure which the bow of the ship must push against at this speed. As a result the total resistance of a ship fluctuates above and below what is known as its "natural" resistance as the speed is increased and as the various progressive wave systems combine to produce beneficial or harmful effects (fig. 7).

The velocity of gravity waves varies as the square root of the product of the acceleration of gravity and the wave length. The forward speeds of the transverse waves generated by a ship correspond to the ship speed V. The interference effects described depend upon a relation between the wave lengths L_W and the ship length L; hence the wave systems are geometrically similar if the ratio of V to the product $\sqrt{gL}$ remains constant, where g is the acceleration of gravity. This ratio is the Froude number $= \dfrac{V}{\sqrt{gL}}$.

D. W. Taylor simplified this relation in the 1900s to the ratio of the ship speed V in knots to the square root of the ship length L in feet. Thus the speed-length quotient = Taylor quotient $T_q = \dfrac{V}{\sqrt{L}}$.

When the estimated wave-making resistance is plotted on a basis of Froude number or Taylor quotient, humps and hollows show up in the curves, as shown in fig. 7, corresponding to the wave-crest

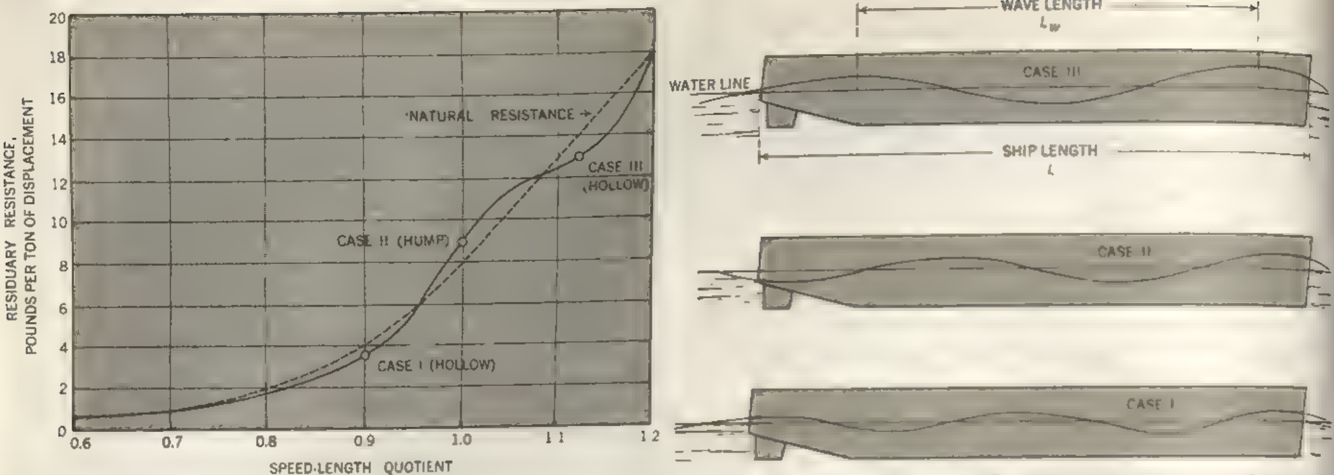


FIG. 7.—WAVE FORMATIONS CAUSING HUMPS AND HOLLOWS IN A GRAPH OF SHIP RESISTANCE. FOR CASE I, $\frac{L_w}{L} = 0.451$; FOR CASE II, $\frac{L_w}{L} = 0.557$; AND FOR CASE III, $\frac{L_w}{L} = 0.698$

and wave-trough positions in the three ship-and-wave profiles of that figure. The naval architect selects a ship length whose wave-making resistance will be less than its "natural" resistance when the ship is traveling at its most efficient speed.

The extreme case in this category occurs with the destroyerlike craft which, at a speed-length quotient of about 2.0 or a Froude number of about 0.6, rides largely on the back of its own first bow-wave crest with its stern in the first trough following. It is, in fact, constantly running uphill; part of its resistance, called the slope drag, is due to this action. A planing boat such as a speed-boat is in a corresponding position, with bow high in the air and stern squatting deeply, when about to pass through what is known as its hump speed. As this speed is reached and exceeded, if the engine has ample power and the boat is not too heavy, the boat approaches and reaches full planing speed. Here it is literally riding on top of the first crest of its own bow-wave system. With its flat stern sliding gracefully over the water there is, in effect, no stern-wave system.

A great deal of theoretical work, having as its aim the calculation of wave-making resistance from the known form of a ship hull, produces resistance curves which resemble those obtained by towing tests in model basins. The work is still limited by certain mathematical simplifications and it appears that more physical laws, not yet fully known, will have to be taken into account before the method becomes practical for engineering predictions.

3. Separation Resistance.—The drag due to separation of the boundary layer from a ship surface, and to eddying and backwash in the separation zone, is a form of pressure resistance. This means that, like wave-making resistance and some types of roughness resistance, it is due to forces exerted at right angles to the hull surface. Like these resistances, it varies usually as the square of the ship speed.

Hydrodynamic knowledge of separation phenomena and the physical laws which govern them has not progressed to the point where the onset of separation can be predicted in advance with certainty and where the magnitude of separation resistance can be calculated. It is known, however, that the pressure in such a zone is less than atmospheric, so that the water literally sucks backward on the ship. If air can be led to the zone to displace the eddying water, the suction is removed. When a motorboat with a square or transom stern extending below the water is speeded up until the stern "clears," the backwash and eddying disappear (fig. 8). With the square stern exposed to the atmosphere, the separation resistance also disappears.

4. Resistance of Submarines.—When a submarine submerges to a depth below the surface equal to four or more times its maximum diameter or its hull depth, the surface disturbance resulting from its forward motion becomes negligible and its wave-making resistance practically disappears. This is a great advantage, especially at high speed, despite the increase in wetted surface and friction resistance caused by taking the whole craft under the water. However, much of the gear above the water line in surface condition, such as flat decks, rails, anchors, capstans, chocks and similar fittings, are put there for operation on the surface. It is difficult to streamline them for low resistance under water. Moreover, minor irregularities which are accepted on the underwater hulls of surface ships become, when taken all together, major sources of added and unnecessary resistance on a submerged submarine moving at high speed.

5. Resistance in Shallow and Restricted Waters.—The forces on a ship traversing shallow waters are governed by the presence of solitary waves caused by ship motion and other disturbances. If the ship speed is slightly less than the solitary wave speed, the ship runs uphill on the back of this wave so that its hydrodynamic resistance is increased by the slope drag. If it can be speeded up so as to run slightly faster than the wave, it slides downhill on the face of the wave and its resistance is reduced below that of its deepwater resistance.

The speed of progressive waves of a given length is less in shallow than in deep water. If a tug, for example, is running at a speed in shallow water at which it has a crest at the bow and another at the stern, its speed must be decreased if the two crests are to be kept at the advantageous positions indicated. At the same time, the crests may be higher and the trough may be lower because waves become steeper as they enter shallow water. A fast

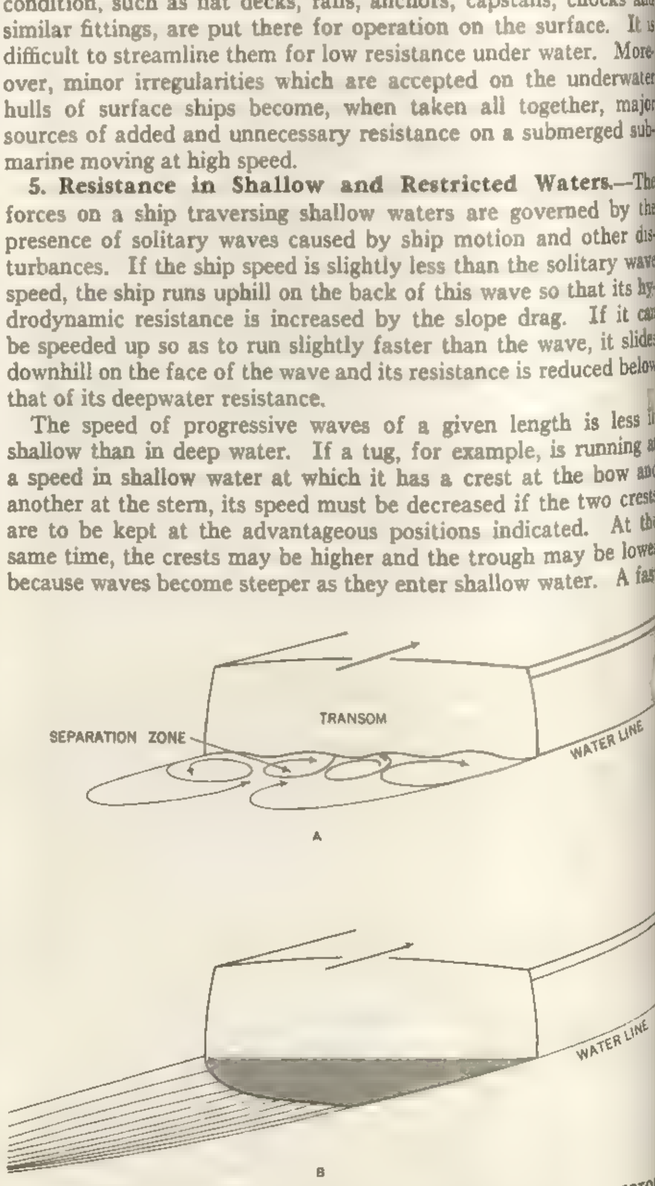

FIG. 8.—SEPARATION ZONE AND AIR FILLED DEPRESSION ABAFT A MOTORBOAT (A) DURING SLOW SPEED AND (B) DURING HIGH SPEED, WHEN THE LOWER TRANSOM AREA IS EXPOSED TO ATMOSPHERIC PRESSURE

craft also squats more deeply at the stern when running in shallow water. In fact, this increase in squat may be sufficient to cause the craft to scrape bottom even though it has plenty of water under it when at rest.

When the clearance between the bottom of the ship and the bed of the water body is initially small, the water that flows under the ship is speeded up, with an increase in friction resistance on the ship. When the sides or walls of the channel are close to the ship, the lateral constriction speeds up this flow still further. Methods of approximating the increased resistance and the depth of water necessary to give the equivalent of deepwater resistance are available, based on the method of O. Schlicting (*Hydrodynamics in Ship Design*, vol. ii, ch. 61, 1957).

Self-propelled craft designed for efficient operation in shallow and restricted waters must have (1) provision for adequate flow of water to the propellers; (2) adequate shielding to prevent drawing air from the surface; and (3) rudders of extra-large area, usually one rudder abaft each propeller, to overcome the horizontal forces resulting from the closeness of adjacent banks or of other craft being met in a channel.

6. Ship Form for Minimum Resistance.—The art and the science of naval architecture have not yet progressed to the point where the form of a ship to meet given requirements, including minimum resistance at a given speed, can be fashioned by a direct method, starting with a clean sheet of paper. Nevertheless, certain general rules based upon hydrodynamics are available: (1) The use of easy and fair surfaces along the general paths followed by the water flow. Small changes of curvature in the flow lines are particularly important. (2) At and near the surface the flow lines must follow the surface or the wave profile. Since most of the wave-making resistance is generated by pressure disturbances near the surface, easy curvature is important there. Proof of good design in this respect is low wave crests and shallow troughs around the ship when running. (3) Most of the flow in almost any type of ship goes under the bottom rather than around the sides, hence the ship form must not interfere with it. (4) Submerged bulbs intended to produce surface-wave systems that will partly neutralize the crests and troughs produced by pressure disturbances elsewhere require careful design and positioning. (5) Probably the most important feature in shaping the hull of a self-propelled craft is to provide a good flow of water to the propulsion devices. So far as known, this calls for the highest practicable degree of uniformity of relative velocity over the whole thrust-producing area, the greatest possible degree of flow opposite to the direction of advance of the blades of the propulsion device and the greatest mass density of the water in which the device is to work. Concerning the last item, it is known that the water entering the propeller disks of destroyers and other high-speed craft contains many air and gas bubbles. In the aggregate, the reduction of mass density due to them can be appreciable.

7. Action of Propulsion Devices.—Thrust by a ship propulsion device acting on the water (or on the air) is produced by imparting sternward acceleration to a mass of that water or air. The forward thrust is proportional to the product of the mass of fluid acted upon and the accelerating rate. For the most efficient propulsion, the mass should be large and the acceleration small. In a screw propeller, this calls for a large diameter and a small increase in relative backward velocity when water is passing through the propeller.

The thrust per blade of a propulsion device is measured by the reduction in pressure on the back or advancing side of the blade and the increase in pressure on the face or after side. As a rule, the former is much larger than the latter so that the blade draws or pulls rather than pushes itself through the fluid in which it works.

Modern propulsion methods for boats and ships include oars, sails, paddle tracks, paddle wheels, hydraulic and pump jets, airscrews, rotating-blade propellers and screw propellers. Screws are usually run in the open but for producing high thrusts at low ship speeds, as when towing, they may be surrounded by a fixed shrouding such as the Kort nozzle. Rotating-blade propellers offer the great advantage that the magnitude and direction of thrust can be varied at will, making them vastly more versatile than any known combination of screw propeller and rudder and giving the craft exceptional maneuverability. A tug fitted with one or more such propellers can exert a pull equally well in any direction with respect to its axis.

The number of propulsion devices depends upon the available power in each engine, the need for reliability or maneuverability, the limiting draft and many other factors. By the late 1950s shaft powers of 25,000 h.p. had been applied to single screws and in excess of 50,000 h.p. on each of four screws.

8. Interactions Between Propeller and Ship.—The operation of a screw propeller involves a number of interactions that are by no means fully understood. Part of the water through which the propeller moves is the boundary layer moving aft past the hull, with a relative velocity less than that at a distance. Another part of it lies within the wave crest (or trough) that runs along above the propeller. Because of these and other effects, the water moves at different velocities and in different directions in different parts of the propeller disk. In general, the ship drags the water along with it to a certain extent, so that its speed past the propeller is less than the ship speed. The difference is the wake velocity, and the ratio of this velocity to the ship speed is the wake fraction.

There are reduced pressures in the region forward of the propeller, resulting from corresponding pressures on the forward sides of the blades. These act to retard the ship, diminishing by a certain amount the usefulness of the full propeller thrust.

9. Efficiency of Propulsion.—The efficiency with which any mechanical propulsion device drives a ship is a product of three separate ratios. The first is the ratio of input to output when the device is running in open water by itself, as when a model is tested in a model basin. The second, known as the hull efficiency, is the ratio of the quantity representing the proportion of useful thrust to total thrust to the quantity expressing the ratio of the speed of advance to the ship speed. The third, known as the relative rotative efficiency, is the ratio of the turning moment on the propulsion-device shaft to produce a given thrust when the device is running in open water to the moment on the shaft when the device is operating in conjunction with the ship.

For ships having screw propellers, the efficiency of propulsion decreases as more propellers are added. It varies from 0.76 to 0.80 or more for a well-placed and well-designed single screw, from 0.65 to 0.72 for twin screws and from 0.60 to 0.64 for quadruple screws such as are carried by large liners and warships.

In practice, the open-water efficiency for a given size of propulsion device is found to vary in almost predictable fashion with the ratio of the thrust produced to the square of the speed of advance. This ratio is known as the thrust loading. Starting with this factor, it is possible to estimate the shaft power required to drive a ship having a known resistance at any given speed.

10. Cavitation.—Any moving submerged body, like a screw-propeller blade, has to push the water aside as it moves. If it moves so fast that the surrounding pressure is not sufficient to cause the water which has been pushed aside to close in around the body and follow its contours, or if the pressure is so low that the same thing occurs when the blade moves slowly, the water either "opens up" or it leaves the blade. In the first case, bubbles are formed in it, each filled with water vapour. When they move along into a region of increasing pressure, they collapse suddenly. The resulting severe pressure fluctuations may cause pieces of the metallic blade surface to break off in an action known as erosion. In the second case, a relatively large vapour-filled cavity is formed next to the blade (fig. 9). This may collapse on the blade or at a distance behind it.

For screw propellers of normal form, any cavity next to the blade interferes with proper flow around it and usually has a harmful effect on thrust and propulsion. Cavitation can be minimized by proper attention to the design of the propeller. The shape selected for the section is one known to be relatively free from cavitation and one on which the reduced pressure is as uniform as possible along the chord (length) of the section, from leading to trailing edge.

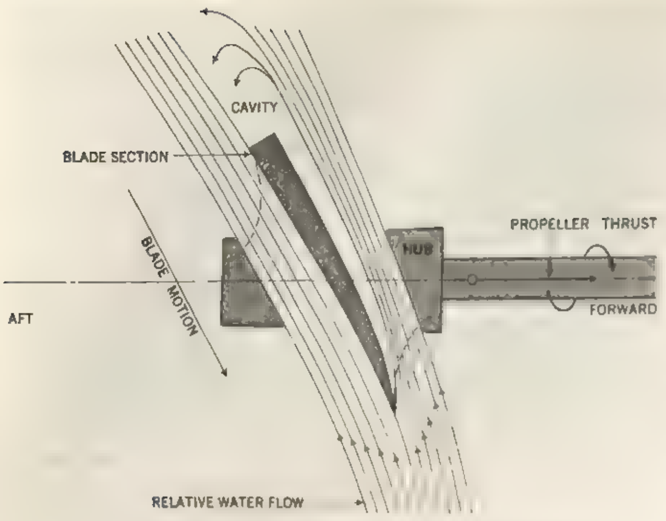

FIG. 9.—SECTION OF A SUPERCAVITATING PROPELLER BLADE

At each radius the blade is made wide enough to carry the local thrust load at the velocity of and at the average water pressure for that radius. The use of large blade areas to delay cavitation must be balanced against the loss of efficiency caused by greater friction drag on the wider blades.

On supercavitating propellers of special design, the blades travel so fast that the water pressure is never sufficient to permit the flow to follow the blade. The vapour cavity is then allowed to expand until it covers the whole back of the blade. The pressure on the back approaches absolute zero while the friction on that side disappears, since the water no longer touches it. Propeller blades of this type, with sharp leading edges and blunt or square trailing edges (fig. 9), have been used successfully on racing motorboats since the 1920s. New techniques developed in the late 1950s permitted them to be designed by logical methods.

11. General Design and Positioning of Propellers.—The propulsion device should be treated as an essential part of the ship, not as a sort of appendage to the hull, and should be designed with it. The flow to and from the propulsion device, whatever its form, is a most important feature from the standpoint of efficient propulsion as well as avoidance of objectionable vibration. Fortunately, it is possible to "see" this flow on medium and large models in circulating-water channels, to study it at length and to correct unsatisfactory features of it while the ship is still in the design stage. Model techniques are also available to give the designer a reasonably good preliminary warning of excessively large periodic forces which may be generated on the ship if corrective measures are not taken.

Because of the great thrust sometimes exerted by the single blades of powerful propulsion devices and the rapid changes of pressure and velocity which take place near them, adequate clearance spaces must be allowed between these blades and the adjacent parts of the ship.

Propulsion devices mounted in transverse ducts or tunnels, extending through the thin ends of the ship from one side to the other, apply transverse forces or swinging moments when the ship is moving or stationary. These devices greatly improve the ship's handling qualities around docks and piers.

On shallow-draft vessels, screw propellers are fitted inside fore-and-aft arch-shaped recesses called tunnels. A large proportion of the propeller area is often above the at-rest water line, but if air is excluded from entering, the tunnel fills with water when the propeller starts rotating, permitting the latter to develop thrust over its entire area.

In many cases it is possible to select the principal features and proportions of a screw propeller by the use of one or more of the many sets of series charts based upon test results of systematic series of propeller models. The disadvantage of this method is that the designer is restricted to the number of blades, blade profiles and blade-section shapes of the models that have been tested. However, there are usually two or three sets of models which approximate what the designer has in mind so that with the data from these he may feel that his combination of tentative characteristics is rather well bracketed. If the designer feels that he may encounter cavitation or if he is able to spend more time on the project, a propeller may be designed rationally by methods described in the technical literature.

12. Model Experiments.—The towing of ship models to determine their resistance and similar characteristics was initiated in 1872 by W. Froude to take the place of limited knowledge of physical laws governing ship behaviour, complexity of the interactions encountered and lack of understanding of the effects of changes in shape and proportions. To make the procedure workable at all, Froude had to separate the friction resistance from the total observed resistance. After subtracting the friction resistance, estimated on the basis of tests which he made by towing flat planks, Froude called what was left the residuary resistance. For corresponding ship and model speeds, where the Froude numbers were the same, he extrapolated the residuary resistance on the basis that this resistance per ton of displacement was the same for both ship and model. The expanded friction and residuary resistances were then added to give the total ship resistance.

In later years, techniques were developed for the testing of propellers, for self-propelling ship models, for determining lines of flow and wave profiles and for measuring the effects of minute changes upon the total resistance. Nevertheless, many of the old problems remain, despite all the time, thought and effort devoted to their solution. Indeed, it appears that advances in knowledge in the field of hydrodynamics raise new problems faster than the old ones are solved. In spite of this, the model-test procedure has been of great assistance to naval architects and, in general, of great engineering value. All the maritime nations of the world have ship-model testing establishments and very few large and important ships are built without first testing one or more models of them.

VI. MANEUVERABILITY

All self-propelled craft, of whatever size, shape, form or type, are required to steer a reasonably straight course in both smooth and rough water, to turn so as to change course or heading or to take emergency evasive action, to start, stop and back and to perform any other desired maneuvers. Submarines are required to maneuver similarly in a vertical plane, including the operations of diving, depth keeping, hovering in one spot and surfacing.

1. Dynamic Stability of Route.—The ease and reliability of steering of a ship depend, among other things, upon whether or not it has dynamic stability of route. A self-propelled ship that is stable in this sense will, if left to itself with no rudder angle applied, continue generally on its original course. If disturbed by some external force, it may swing slightly or moderately to a new course, whereupon it will continue along that course or route until again disturbed. Most slender ships like destroyers are dynamically stable in route. Others of fat or chubby shape, if left to themselves and then disturbed, will swing farther and farther from the original route. A sign of route instability is the persistence of the ship in swinging one way after moderate corrective or opposite rudder is applied to stop the swing. A ship of this type may become positively unmanageable in shallow water, where the sluggishness of any ship is intensified.

2. Steering and Turning.—Steering involves corrections to bring a ship back to a given course or heading after it has deviated as a result of some disturbance. Steering by hand control is easier and more efficient if instruments in front of the steersman show almost instantly when these deviations begin. Gyrocompasses are far more satisfactory than magnetic compasses for this purpose. Further, a ship that is dynamically stable in route, but not too much so, and one that is not oversteered, requires only a small rudder angle and relatively infrequent use of the rudder. Automatic steering by gyro pilot is available for all sizes and types of ships.

Turning is involved when changing course, when maneuvering in formation with other ships and when following a curved channel.

However, the most important turning maneuver for any ship is to sheer off suddenly and to get clear of its original course when danger is unexpectedly sighted ahead along that course. To clear the extension of its original path in the shortest distance and the least time, assuming that the ship is going too fast to be stopped completely, requires rapid laying of the rudder to the emergency angle, rapid response of the ship in starting to turn and rapid motion of the ship to the right or left of the course to clear the danger ahead.

The rudder action serves not only to swing the ship in the desired direction but also to keep its bow pointed inside the path of its centre of gravity so that the inward-acting hydrodynamic force on the hull equals the outward-acting centrifugal force resulting from motion in a curved path. The amount by which the ship heads inside the instantaneous direction of motion is the drift angle.

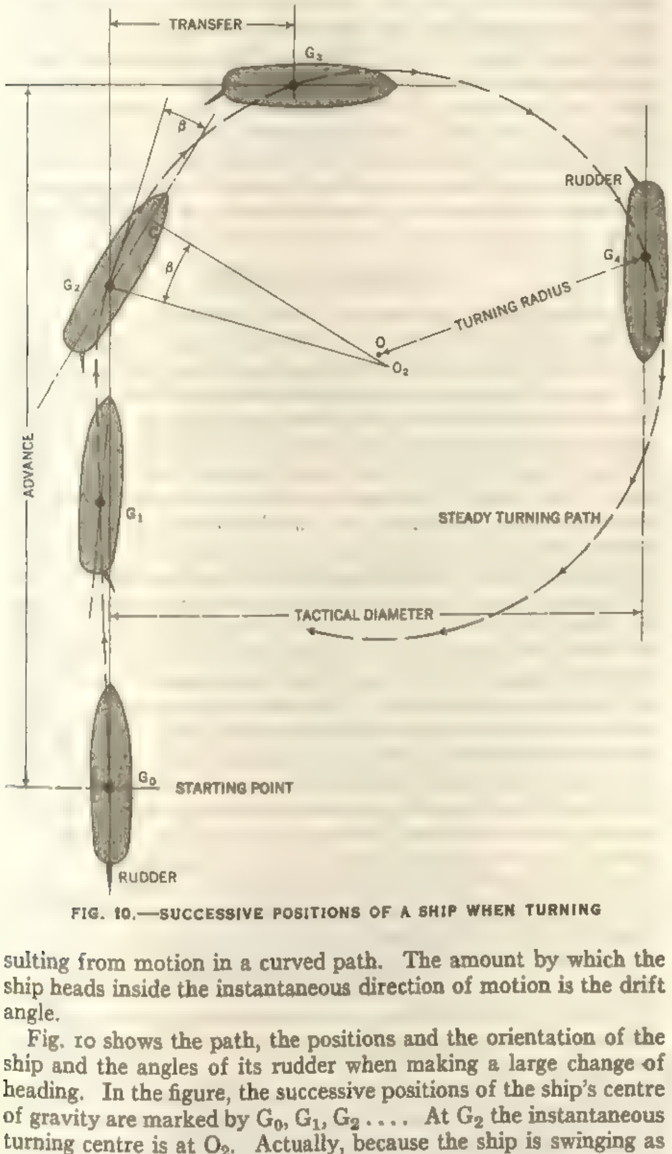

FIG. 10.—SUCCESSIVE POSITIONS OF A SHIP WHEN TURNING

Fig. 10 shows the path, the positions and the orientation of the ship and the angles of its rudder when making a large change of heading. In the figure, the successive positions of the ship's centre of gravity are marked by G_0, G_1, G_2 . . . . At G_2 the instantaneous turning centre is at O_2. Actually, because the ship is swinging as though attached to a rotating arm, the water seems to be approaching it along curved streamlines, nearly head on at the bow and at a considerable angle inward toward the stern. This angle of relative flow, involving cross flow at the stern from the outside toward the inside of the turn, acts to reduce the effective angle of attack of the rudder. At the point C the nominal flow about the ship is parallel to its centreline. To an observer on board, the ship appears to be turning about this point, hence it is called the pivoting point.

In the course of turning, especially with a large drift angle (β), the increased hull resistance causes the ship to slow down, sometimes involving a reduction of 40% or more of the speed with which it approached the turn. After the average ship has turned at least 90°, conditions become steady and its centre of gravity moves at uniform speed in a circular path with its centre at O.

In the steady-state portion of the turn the inward force caused by the drift angle exactly balances, in both magnitude and moment about the centre of gravity, the outward rudder force and the centrifugal force at the centre of gravity caused by the turning action. If the wind and sea were entirely quiet, the ship would continue to turn in a steady circle as long as the rudder was held at a constant angle and the speed remained constant.

Ability to steer a straight course or to turn readily is achieved in any given ship design by the use of a large rudder area. When the rudder is at zero angle, it serves as a vertical stabilizing fin. When angled, the large area provides the large swinging moment necessary for good turning.

3. Stopping and Backing.—Stopping in an emergency, as contrasted with normal coasting and gradual retardation, is achieved by slowing the propulsion device to less than driving speed and then by reversing its direction of thrust. If reversed too rapidly it is liable to overload the engine, to draw air down from the surface to the propeller in large quantities and to churn the air-water mixture into excessive turbulence without developing the maximum astern thrust. Capacity to start and stop quickly is built into a craft by providing an engine that will reverse rapidly and readily and by using a propulsion device with a large thrust-producing area. Both these features are stressed in the design of tugs.

4. Rudders and Planes.—Rudders and other control surfaces are usually placed at the stern of a ship for several reasons. When placed abaft screw propellers, they benefit from the increased velocity in the propeller outflow jet or race. When a vertical rudder is placed at the bow, it causes the ship to turn with a smaller drift angle and hence a larger turning radius. If the rudder is attached to the bow, it is ineffective hydrodynamically in producing a swinging moment. In fact, a normal ship, when moving backward, steers only indifferently or not at all. The rudder also receives better mechanical protection at the stern than it would at the bow.

For craft that are required to back out of long slips, or even to back into harbour entrances, like the English channel ferries at Dover, a rudder is fitted at the bow. This becomes the trailing end when backing, and the ship steers satisfactorily with a rudder at that end.

A centreline rudder mounted between two widely spaced wing propellers benefits only little or perhaps not at all from the augmented water velocity in the propeller outflow jets. Adequate swinging effect is then achieved by mounting two rudders abreast, one abaft each propeller.

The diving planes for controlling the rise and dive angle of a submarine are placed at the stern, directly abaft the propellers, to benefit from the higher water velocity in that region (fig. 11). Bow planes, if fitted, are used principally to control the depth at which the craft runs. They are effective as control surfaces because only vertical forces, not swinging or diving moments, are

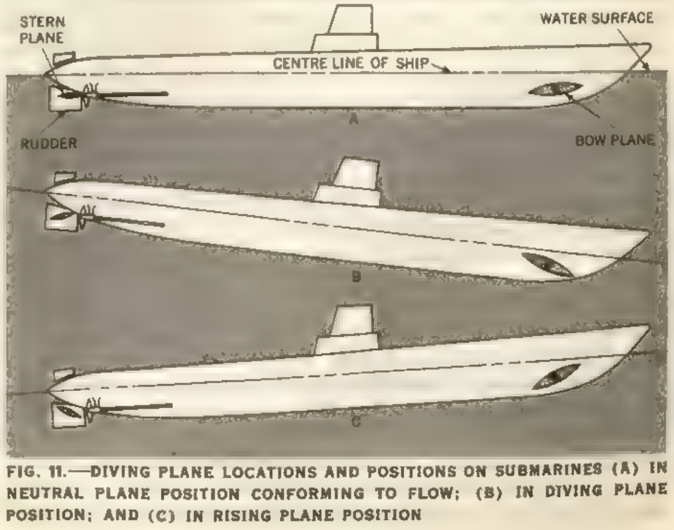

FIG. 11.—DIVING PLANE LOCATIONS AND POSITIONS ON SUBMARINES (A) IN NEUTRAL PLANE POSITION CONFORMING TO FLOW; (B) IN DIVING PLANE POSITION; AND (C) IN RISING PLANE POSITION

desired and because they project from the hull and create up or down forces independent of the hull forces.

Control surfaces called flanking rudders are placed forward of the screw propellers on shallow-draft push boats to produce side forces when the propellers are rotating astern. They enable these craft, when pushing groups of barges 1,000 or more feet in over-all length, to maneuver around river bends and through channel turns.

5. Heel When Turning.—In a turn, the inward hydrodynamic force produced by the drift angle is applied at a point well below the water line. The outward centrifugal force is applied at the centre of gravity, usually located at or above the water line. This couple acts to heel the ship outward to an angle at which it is balanced by the righting moment resulting from the transverse metacentric stability. The contribution of the rudder to this pattern is a force acting to reduce the angle of heel. Thus, in a steady turn, if the rudder angle is suddenly removed, the outboard heel is momentarily increased. Ships with small metacentric stability and comparatively large rudders have capsized through this cause.

Submarines with large, highly streamlined fairwaters around the periscopes and masts heel inward on submerged turns, especially if running at more than low or moderate speeds. This is because a large part of the inward hydrodynamic force is generated by the drift angle on the fairwater. This force acts inward at a level well above the centre of gravity, where the outward centrifugal force is applied. The outward lateral force on a rudder mounted below the main hull acts at the same time to increase the inward heel.

6. Effect of Propulsion-Device Action on Maneuverability.—The individual thrusts of independent wing propellers, with axes offset from the centre of gravity, exert a swinging moment about that centre. Ships with the rudder damaged or lost have been steered by suitable operation of the wing propellers. On some ships, pushing ahead on one screw and pulling astern on the other acts to turn the ship around almost on its own centre. Tugs with port and starboard paddle wheels driven independently, or with rotating-blade propellers, can maneuver even more readily in this fashion.

Blades of stern propellers that encounter crossflow under the ship when swinging or yawing produce lateral forces that counteract the swinging motion and increase the diameter of the turn. If air is drawn into the upper blades of the propeller on a single-screw ship, excess lateral forces on the lower blades swing the stern in the direction that the upper blades are moving, say from port to starboard. To a certain extent these forces can be counteracted by the rudder but for the most part the operator of a single-screw ship must foresee their existence and make adequate allowance for them.

7. Maneuverability of Submarines in the Vertical Plane.—Many of the factors involved in the steering and turning of ships in the horizontal plane apply also to the depth keeping, rising and diving of submarines in the vertical plane. The problem is much more severe here, however, because of the extreme relative thinness of the layer of water between the surface and the permissible working depth. The situation is somewhat similar to that which would confront the pilot of a transport airplane if he knew that at an altitude above 500 ft. his craft would disintegrate.

The undersea craft, required to run at almost constant depth for extended periods, requires reasonable dynamic stability of route in the vertical plane. It also requires controllability at extremely low submerged speeds so that it may hover at one spot or creep along slowly, without making any noise. Should the submarine crew lose vertical control with the craft headed for dangerous depths, a high-pressure air-blowing system serves to expel some of the water in the main-ballast tanks. The additional buoyancy thus gained checks and stops its descent.

8. Maneuvering Predictions and Model Experiments.—The ultimate aim of the naval architect is to formulate and collect rules and formulas by which a ship may be designed directly or by which its behaviour and performance may be predicted directly. The first are available in small part; some data for the second have been derived by tests under model towing carriages and rotating arms. These serve to determine the forces and moments resulting from elementary motions such as ahead motion with yawing deviations and motion at various drift angles when the centre of gravity is moving in a circular path, simulating a steady turn. The forces and moments are then fed into the equations of motion as outlined, for example, by K. S. M. Davidson and L. I. Schiff (*Transactions of the Society of Naval Architects and Marine Engineers*, 1946) and the integrated performance is predicted therefrom. This approach has been used primarily for the determination of dynamic stability of route, which involves only fairly small angles of attack and angular velocities. When these motions become large, as they do for large course departures, this approach can be used only with large empirical corrections.

Free-running self-propelled ship models, sometimes radio controlled, can simulate turns and other maneuvers, permitting derivation of the path of the centre of gravity, changes in forward speed, rudder angles, angles of heel and related data. Self-propelled models, supplied with power and steered by distant control from a towing carriage following, provide experimental checks on steering, dynamic stability of route, effectiveness of rudders and certain maneuvers which can be performed within the limited width of a model testing basin.

VII. SHIPS IN WAVES

Considered as the environment for boats and ships of all kinds and sizes, the term sea is used to denote all waters large enough for the operation of these craft, from creeks and ponds to lakes and oceans. The wind and the ships moving across the sea create a pattern of undulations ranging from minute ripples to waves of gigantic size. The currents moving through it must also be taken into account in all ship operations and in some ship-design problems. The variations in density, resulting from the amount of salts in solution, determine the variable-ballast tank capacity of submarines and the ability of a submarine to "sit" on a layer of dense water while largely supported by a less dense layer above.

Considering the over-all surface configuration, termed the seaway, the classical concept of a train of regular waves is highly unrealistic but it has some practical uses. The normal seaway is highly irregular, with waves of different heights and lengths traveling in many directions. For analytic purposes, it may be considered as made up of a multitude of very low waves, having the actual lengths and periods of all the sea waves and traveling in the same directions, superposed in quantity to produce the actual seaway. When this is done, a promising approach is to accept a multicomponent, random nature and to use statistical methods to define the seaway (*see* WAVES OF THE SEA).

The sea is also home to teeming masses of marine life, many of which are detrimental to ships. Marine borers attack wood exposed on underwater portions of the hull. Barnacles cling to the underwater hull, roughening its surface and increasing the ship's resistance to travel through the water. Sea water is highly corrosive to most materials, and severe electrochemical effects cause rapid disintegration of submerged metals that are unprotected.

1. Ship Motions in Waves.—Treated as a rigid body, a ship partakes of six oscillatory motions in a seaway. Three are translatory motions of the whole ship in one direction: (1) surge is the oscillation of the ship fore and aft; (2) sway is the motion from side to side; and (3) heave is the up-and-down motion. The other three oscillations are rotary: (4) roll is the angular rotation from side to side about a fore-and-aft axis; (5) pitch is the bow-up, bow-down motion about an athwartships axis; and (6) yaw is the swing of the ship about a vertical axis. Yawing is not necessarily oscillatory for every service condition. All six of these motions can and do take place simultaneously in a confused sea, so the situation is most complex.

The forces and moments caused by waves are balanced by three types of forces and moments opposing them: (1) those required to move the ship and cargo and the adjacent water to which kinetic energy is imparted by the ship motion; (2) those absorbed in damping the oscillatory ship motion or reducing its extent by the

generation of surface gravity waves, eddies, vortexes and turbulence; the energy required for setting up these disturbances is carried away and lost; (3) those of hydrostatic or hydrodynamic nature that act to restore the ship to a position of equilibrium as, for example, when the ship rolls to an angle greater than that called for by the exciting moment.

2. Effect of Shape and Proportions.—The most important single factor in cutting down the increased resistance of ships running in waves appears to be a small fatness ratio; in other words, a small underwater volume compared with the ship length. This slenderness is difficult to work into ships intended to carry cargo, but relatively easy for passenger ships. For reduction in the magnitude of ship motions in waves it is important that the damping forces and moments be as large as practicable. Moderate flare in the above-water sections at bow and stern, large beam compared with draft and fineness of the underwater sections all help to achieve this result. A deep-sea sailing yacht embodies these characteristics to a high degree.

To keep the ship reasonably dry while undergoing the rolling, pitching and heaving motions that remain, large freeboard is essential, especially at the bow. In fact, to prevent slamming under the bow when it lifts out of water and then drops heavily upon the surface, the forefoot under water must also be deep.

A good degree of damping is most necessary to avoid deep rolling. If this cannot be achieved by a transverse form suited to the service, such as that of a sailing yacht with a deep fin keel, it is accomplished by adding long fins on each side in the form of roll-resisting or bilge keels. When placed along the lines of flow, these keels add little to the ship resistance in calm water.

Active roll-resisting fins serve to quench the greater part of the roll on a fast ship with a reasonable expenditure of weight, space and cost. These fins, much shorter than bilge keels but extending several times as far outboard when in use, are rotated mechanically about transverse axes to produce angles of attack and girthwise forces which continually oppose the rolling motion. Since the moments of the roll-resisting forces diminish as the square of the ship speed, the active fins are ineffective at low speeds.

Active roll-resisting tanks of U shape have been built and tested in ships. In these, water or other liquids can be transferred rapidly from one side of the ship to the other to counteract the rolling motion, using controllable (and reversible) axial-flow propellers placed in ducts connecting the port and starboard tanks.

Considering the vertical accelerations involved, pitching and heaving, or a combination of the two, are the most objectionable for passenger comfort and safeguarding of cargo. Some form of passive pitch-resisting fin may be evolved which will accomplish its primary purpose without introducing detrimental features.

3. Hydrostatic and Hydrodynamic Loads in Service.—The naval architect must know the loads imposed upon a ship in all the conditions of its expected service in waves so that he may design the hull structure to withstand them. Aside from the static distribution of load along the length when the ship is floating at rest in calm water, there are many other buoyancy distributions in waves for exactly the same loading condition of the ship. Further, the wave action and the ship motion in waves generate dynamic forces which, under certain conditions, may be extremely important. When the bow and stern are on wave crests, with a wave trough between, the ship hull sags or bends downward in the middle. As the middle body reaches a wave crest, with the ends over wave troughs, the ship bends the other way or "hogs" and the ends droop because of the greater buoyancy amidships. Waves also produce torsional moments and the hull twists in the seaway, as when the ship is traveling obliquely through waves. Both bending and twisting actions involve shear in the structural members, as when a region that was square in shape under no load takes the shape of a rhombus when deformed. When the ship rolls, racking strains are induced in the hull because the above-water portion wants to continue to roll as the underwater portion starts to roll back the other way. Ship motions also induce inertia forces similar to those felt in elevators when starting or stopping.

It often happens that a part of the hull and an adjacent wave surface, each parallel to and approaching the other, meet with a heavy shocklike impact known as slamming. This can occur if the bow of a ship emerges from the water on a violent up-pitch and drops down upon a rising wave surface. It can also occur if a large wave strikes an overhanging part of the ship, such as the flaring hull under the forward end of the flight deck on an aircraft carrier. The tremendous blow against one end of the hull causes the whole structure to vibrate in an action known as whipping. The strains thus caused may be as great as those encountered in sagging and hogging over large waves.

Other natural loads are those caused by wind and ice. Typhoon and hurricane winds may blow with velocities of 100 knots or more. In subfreezing weather the sea spray freezes on the exposed portions of the ship, thereby adding a substantial weight. Icebreakers must be able to withstand the shock of ramming thick, solid layers of sea ice and to survive the squeezing action of pack ice.

Many of these loads may be reduced by judicious operation of

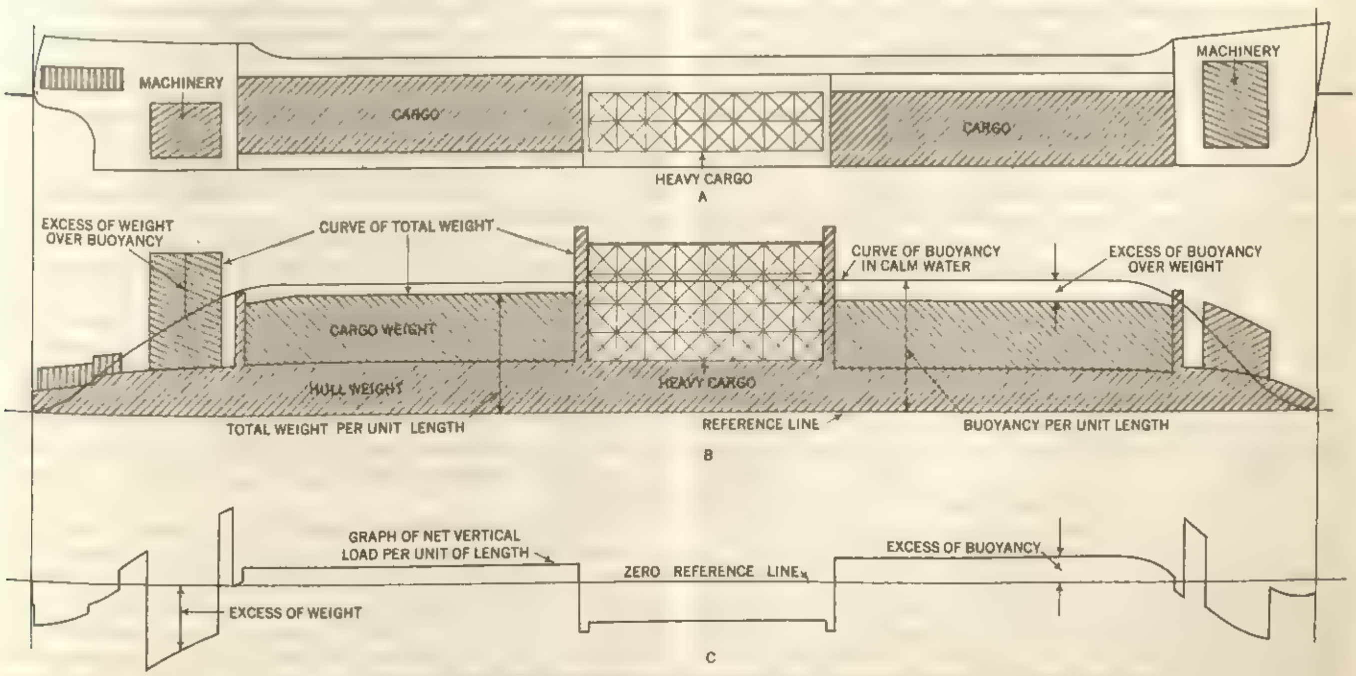

FIG. 12.—DIAGRAM SHOWING VARIATION OF WEIGHT AND BUOYANCY ALONG THE LENGTH OF SHIPS (*See text*)

the ship; for example, by slowing down or heaving to in a storm. Ship structures are designed to withstand most of them, but the exercise of good seamanship significantly lessens their intensity.

4. Variation of Buoyancy and Weight Along the Length.—At a given draft and trim in calm water, the upward buoyancy forces vary from bow to stern in a fixed fashion because each unit length of the ship is supported by a force equal to the weight of water displaced by a transverse section of unit length at that point. When summed up, all the buoyancy forces on the unit lengths equal the total ship weight. The fixed or "hardware" weights of the ship structure, the machinery, the fittings, the equipment and the fuel and stores, have a somewhat different bow-to-stern distribution when reckoned by the same unit lengths (fig. 12). If the ship is loaded with cargo, so that the fore-and-aft distribution of total weight is shown by the total hatched area in fig. 12(B), some unit lengths weigh less and some more than the water displaced by the immersed volume in those lengths. Fig. 12(C) indicates the irregular nature of the net weight or buoyancy forces at all points along the ship length.

Cargo loaded at the ends aggravates this condition and creates an elastic hogging deformation, with the midship portion bent upward and the ends drooping. Cargo loaded in the middle, with the ends empty, creates a sagging of the structure, with the midship portion bent downward. As a first requirement, the ship structure must be strong enough to take care of all the nonuniform weight distribution in calm water during normal loading and unloading. The bending caused by uneven loading, in a tanker carrying liquids and floating in still water, can be sufficient to crack the structure or to break it in two.

When the ship is in waves, the upward buoyancy forces are greatest in way of a crest and least in way of a trough while the ship and cargo weights and the distribution of these weights along the length remain the same. Since two successive waves are rarely alike, it is customary to design the hull structure to withstand the bending moments, in both hogging and sagging, produced by some assumed "standard" series of waves. One such wave has a vertical height in feet, from trough to crest, of 1.1 times the square root of the wave length in feet. This takes care of the observed fact that short waves, the most severe for small boats and ships, have height-to-length or steepness ratios greater than those of long waves. All the "standard" waves have lengths equal to the ship length.

5. Determination of Forces and Moments.—The maximum forces that a ship is likely to encounter in service, excluding temporarily those due to above-water or underwater explosions, are the weight and buoyancy forces that act vertically, caused by gravity. The moments of greatest interest to the designer are the maximum bending moment in the vertical fore-and-aft plane, for both the hogging and the sagging conditions on the assumed "standard" wave. Slamming forces may act in almost any direction, and they are usually applied at or near the ends of the ship. To predict them it is necessary to make certain assumptions and to use certain approximate formulas not described here.

Prediction of the forces and moments due to above-water or underwater explosions—a possible emergency load for all ship types—requires specialized knowledge and a great deal of experience, much of it of a secret or confidential status. Aside from direct or close hits, the explosive forces produce vertical and lateral bending and whipping, much as do the waves of the sea.

The procedure for determining the vertical bending moment is to consider the ship poised and balanced statically on the assumed wave. This means that the buoyancy graph in fig. 12(B) is replaced by one based on a curved "standard" wave profile instead of a straight one, with a crest either at mid-length or with two crests at the ends. The wave profile must be adjusted on the ship profile until the total buoyancy forces equal the total weight of the ship, and the centre of gravity is vertically in line with the centre of buoyancy. With the ship balanced on the wave a load curve similar to that in fig. 12(C) is drawn, showing the differences between weight and buoyancy at all stations along its length. At any transverse section, the vertical shear is determined by summing up the area under the load curve from one end of the ship to the section in question. By a process known as integration of the moments about a given station, the vertical bending moment curve is obtained.

6. Superposition of Calm-Water and Dynamic Wave Loads.—The final forces and moments which a ship structure is designed to withstand must take account of those imposed by the static loading, such as those due to cargo, fuel and stores loaded at a pier in port (fig. 12), plus those imposed by wave action and ship motion after the ship puts to sea. In fact, under some service conditions the calm-water bending moment may exceed in magnitude the wave-and-motion movement in a seaway.

VIII. STRENGTH OF SHIPS

A ship hull, of whatever materials it may be made, must be strong enough to withstand all the loads that may be imposed upon it by normal service and by any seaway that may be expected during its life. It must, in fact, have a reserve of strength to take care of excessive loads carelessly or negligently applied or of loads caused by unusually high, large or steep waves. The latter are encountered only on rare occasions, but they do occur.

The structural configuration, involving the disposition of material as well as the elasticity of that material, must be such that the structure does not bend or flex unduly under the specified loads. It is customary to make a ship hull much stiffer than, say, the wings of a large airplane, just as the fuselage of that plane is stiffer than its wings.

The material must be so disposed and proportioned that the hull has the minimum weight—and can be built for the minimum cost—to perform all its functions acceptably. A knowledge of how the various parts are strained, of how the applied loads are distributed among the various members and of how all of them work together is essential in order to place and proportion them in the most effective manner.

1. Strength and Stiffness.—A ship structure is sufficiently strong if it can support all the fixed loads of its machinery, fittings and equipment and all the cargo loads, and if it can withstand without permanent change of shape, cracking and fracture all the hydrostatic and hydrodynamic loads which can be imposed upon it in calm water or in any kind of seaway in which it is supposed to operate. It is sufficiently stiff if, under any of these service loads, it does not flex or deform unduly so as to interfere with the alignment of operation of machinery or with any other function, major or minor. A bronze screw propeller of a high-powered ship, having blades that are too thin, may deform so much when generating full thrust that its shape and propulsive characteristics are changed. If the blades are permanently bent under emergency maneuvering conditions, the propeller is not strong enough.

Vibratory motion can build up to unacceptable peaks if local portions of the structure are in resonance with the periodic applied forces. In consequence, rudder plating and shell plating at the stern must be stiffened to control panting or pulsating deflections from propeller forces. The shell at the bow is also subject to panting from wave-impact loadings; this requires extra stiffeners, called panting stringers.

It is customary in ship structures and ship components to limit the calculated strains under the heaviest contemplated service loading to a certain fraction of the limiting strain for the material being used at which permanent change of shape or damage will occur. The margin thus provided takes care of unusual and emergency conditions which rarely can be foreseen at the time of design. For a submarine pressure hull the collapsing depth is calculated—or determined by model tests—as part of the original design. It is considerably greater than the working depth, at which the calculated strains are limited to values which can be endured indefinitely.

2. Structural Configurations.—The arrangement and disposition of the structural material in a hull and the proportions of the structure, all known as the configuration, are most important features. A too-shallow ship hull, like a too-shallow bridge truss, requires an inordinate amount of steel for strength and stiffness. A hull that is too deep also requires too much steel because of its size, unless the various members are made too thin. Structural

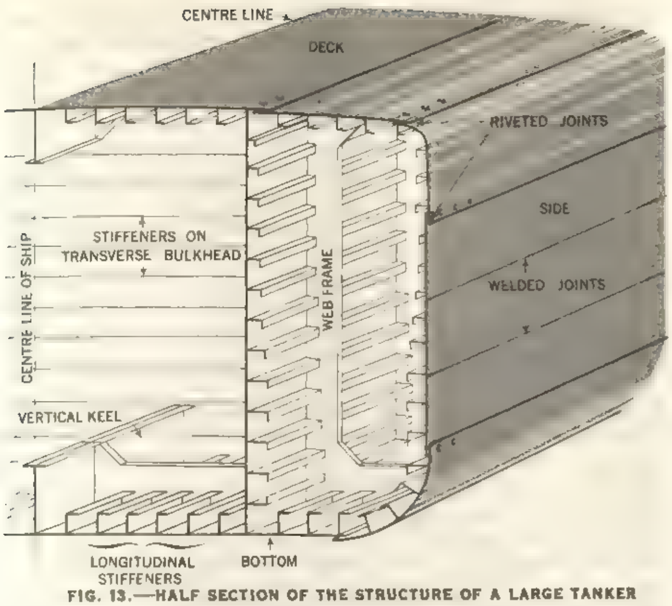

FIG. 13.—HALF SECTION OF THE STRUCTURE OF A LARGE TANKER

material in the form of a closed box, like a ship hull with a deck, resists vertical and lateral bending and twisting all at the same time.

It is important, for cost and weight as well as for strength and stiffness, that the structural material be placed in the ship where it will do the most good. If there is too much material in the bottom structure and not enough in the decks, the neutral axis of the section (above and below which the moment of area through the structural members is the same) will be too close to the bottom.

For a given bending deformation the upper members will be unduly strained and the lower members only partly strained. It may be advantageous to make the hull girder deeper amidships, by about one deck height, where the vertical bending moment is greatest, and shallower at the ends, where it is least.

Every boat or ship hull, both above and below the water, embodies a watertight boundary or shell which provides the buoyant volume to float it. Taken with a deck to which it is firmly attached, the whole forms a hollow box, a most economical and efficient principal structural member of the hull. Since some part of this box is in compression for bending loads, and much of it is in shear for twisting loads, the relatively thin shell—bottom, sides and deck—must be prevented from buckling, crumpling and wrinkling when it is strained. This is done by stiffening it at intervals with frames and stringers of some convenient type. They hold the flat surfaces in shape and take some of the working loads as well (fig. 13).

When the stiffening system of the deck and shell plating lies predominantly parallel to the principal ship axis the ship is said to be longitudinally framed. When the majority of stiffeners lie at right angles to that axis, it is transversely framed. Whatever the system of deck and shell stiffeners, they must be supplemented by deep web or belt frames in the first case, placed transversely (fig. 13 and 14), or by longitudinal stringers in the second case, run fore and aft. These hold the primary stiffened system in shape and help to distribute concentrated loads resulting from nonuniform placing of cargo, wave action on the outside, and external blows from striking piers and quay walls and rubbing against fenders and the sides of other ships. Longitudinal framing saves hull weight because the metal in the fore-and-aft stiffeners supplements the metal in the shell and the uppermost decks in resisting the bending moments imposed in vertical and horizontal planes.

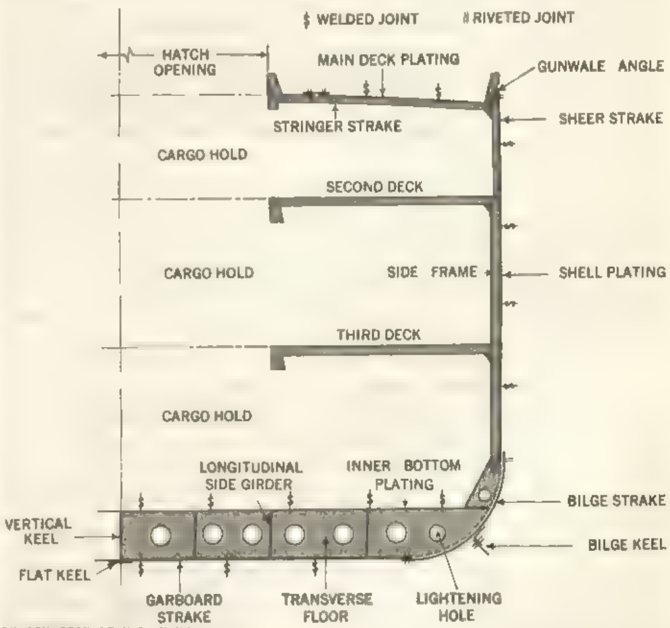
FIG. 14.—HALF SECTION OF A LONGITUDINALLY FRAMED DESTROYER

Fig. 15 shows the hull structure for a typical transversely framed cargo ship (1953 "Mariner" class, U.S.). The construction is predominantly welded. The riveted joints at bilge strake, gunwale and main deck, just outboard of the cargo hatch, function as crack arresters in case of progressive failure of the wide, flat, welded areas. The inner bottom plating forms part of the bottom flange of the ship girder; in addition, it is made watertight so that it serves as a tank top and as an additional watertight boundary if the outside plating at the bottom is pierced.

The transverse and longitudinal bulkheads required for subdivision, the internal platforms and decks required for service, access and storage and the boundaries of internal tanks for liquids are utilized for structural strength wherever practicable, to avoid unnecessary weight.

3. Scantlings and Strength Calculations.—When a structural configuration has been sketched, conforming satisfactorily to the ship arrangement, the designer selects the scantlings, defined as the size, shape, area and unit weight of the individual structural members. This is done first for the midship section, where the vertical bending moment is usually the greatest. The preliminary scantlings are chosen from experience, from a ship generally similar, from classification society rules or by a scientific analytic process.

The parts of a ship structure that make up the hull girder resisting the longitudinal bending moments must at the same time carry the more localized loadings, such as concentrated machinery loads and large external water forces. Often the latter govern the design of the part. The transverse bulkheads and the transverse web frames are designed on the basis of local loads. Watertight bulkheads are required to resist maximum water pressure when the compartment on one side is flooded.



BY COURTESY OF U.S. NAVY

FIG. 15.—HALF-MIDSHIP SECTION OF A TRANSVERSELY FRAMED CARGO SHIP

Gun and launcher foundations present special problems. They are designed by assuming various directions of impulse or recoil to find the critical direction for each important member of the foundation.

4. Structural Design of Submarine Pressure Hulls.—The depths to which combat submarines are required to submerge and the necessity for conserving weight in the inner or always-buoyant hulls of cargo submarines call for correct proportioning of the structural elements and accurate selection of thicknesses for the various parts. The uniform pressure around the entire inner hull at working depth enables the designer to calculate the exact hydrodynamic loads, but the fact that the entire structure is loaded

in compression and that the inner shell may be expected to fail by buckling more than makes up for the simplicity of loading.

The lightest pressure-resisting inner-hull form is a cylinder of circular section, stiffened by ring-shaped frames with a longitudinal spacing of from one-fifth to one-tenth or less of the diameter, depending upon the specified working depth and external pressure (fig. 16). Whether riveted or welded, the plates forming the circular sections are butted together at their fore-and-aft joints, so as to transmit the compression loads directly from one plate to the other. Theoretical formulas, supplemented and confirmed by the tests of many hundreds of scale models of steel, enable the designer to determine the plating thickness, the frame spacing, the form and size of the frames and the best method of attaching the frames to the cylindrical shell.

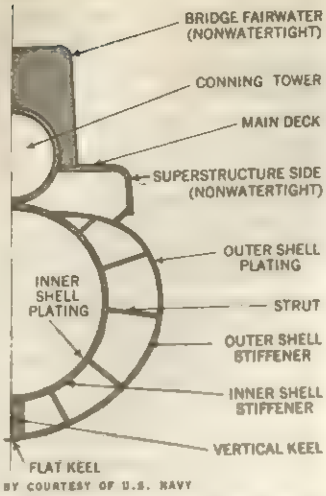


FIG. 16.—HALF-MIDSHIP SECTION OF A SUBMARINE

At each end of the submarine hull, where it diminishes in beam and depth to facilitate propulsion, the inner hull takes the form of the frustum of a cone, with circular or elliptical transverse sections of reduced diameter.

5. Detrimental Effects of Discontinuities.—The various parts of a ship hull made of elastic material are found to stretch, shorten, twist and flex as the external loads cause the whole hull to change shape. If the adjacent parts cannot deform locally by about the same amount, the heavier and stiffer members pull or push on the lighter ones.

The result may be excessive local strains, out of all proportion to the strains which would be caused normally by the principal external load. After reaching the fatigue limit the local metal may crack, buckle or break. Good structural design calls for the tapering or narrowing of members to correspond to the strength and rigidity required, and for great care in making transitions from heavy members to lighter ones along a given line of application of a load.

6. Materials of Construction.—Wood was for many centuries the most important and, in fact, the only shipbuilding material. It is still used for boats and small craft of many types, as it is easily handled and worked by local craftsmen with simple tools. However, it is a relatively weak material and is subject to rapid deterioration. Slippage along fore-and-aft flush seams is difficult to prevent. Large wooden ships had to have diagonal metal straps bolted to the planking to counteract slipping at the seams and to keep the hulls in shape. Others made use of hogging girders or tie rods running over high vertical posts to prevent the ends of the hulls from drooping. Many modern metal ships have wooden weather decks to help insulate the spaces below and to provide a good walking surface.

The development of strong waterproof glues and techniques for building up large curved members from thin laminations has greatly improved the strength and stiffness of wooden ship structures. Checking, splitting, knots and other imperfections are largely eliminated, and many short pieces can be used. Molded plywood yacht hulls made of five thin layers glued together, with the grain running in different directions, are stiff enough to hold their shape without an internal framework.

The steels most widely used for hull structures are of the medium, high-tensile and special-treatment types. By far the greatest proportion of parts are of medium steel, where the working strains are small or moderate compared with the yield strain. Both high-tensile and special-treatment steels have higher yield points; the latter has ballistic and shock-resisting properties as well. They are used for parts subjected to high strains in order to save hull weight.

Investigations in the latter 1940s revealed that many of the fracture casualties of that period were due to the use of steel lacking in notch toughness. This term refers to the steel's ability to absorb energy by stretching in the vicinity of sharp corners, notches and cracks, particularly at low temperatures or at high stretching rates. This quality is particularly important where all the plating seams around the girth are welded. Many ship structures have several riveted seams to permit adjustment of the strains due to butt welding and to localize progressive cracking. Specifications for shipbuilding steels of the 1950s required certain minimum limits on notch toughness and on adaptability to welding.

Aluminum alloys are used for the hulls of small and experimental craft and for large shipboard elevator platforms and similar structures. They are also used for the superstructures and upper works of many cargo and passenger vessels; they form the upper parts of steel hull girders which bend elastically in service. For the last-named purpose, the increased deformation or stretch of these alloys is an advantage. For a given weight, panel plates of aluminum alloy are thicker and stiffer than those of steel. They thus provide a better appearance and for many installations they do not require painting.

Use of aluminum for large ship structures, such as the hull proper, in which appreciable savings in weight are to be achieved, requires reliable welding and riveting in large thicknesses. What is more, it necessitates the acceptance of increased bending deformations along the length and lowered natural frequencies of vibration as compared with similar structures of steel.

Hulls of heavily reinforced concrete have been used for ships and barges in times of emergency, when steel reinforcing rods and labour trained in building construction were available and shipbuilding steel and labour having shipbuilding skills were not.

Plastics reinforced with glass fibre eliminate many of the joints in a hull and greatly decrease the deterioration encountered in wooden or metal hulls. They may be coloured with pigment and they lend themselves admirably to "sticking in" stiffening members and other parts and to repairs in a similar manner when damaged. Many nonstructural parts of boats and ships of all sizes and types are easily fabricated by molding in reinforced plastic.

7. Jointing, Connections and Attachments.—It is possible, with Fiberglas and similar materials, to make a small-boat hull entirely in one piece. However, as the boat becomes large enough to require a Fiberglas deck, this is made separately and attached to the hull. For larger craft, the individual planks and plates have to be joined by gluing, screwing, bolting, riveting or welding (*see* also RIVET; WELDING). Flush seams (fore-and-aft joints) and butts (girthwise joints) for smooth external hull surfaces are possible by gluing and welding. Screwing, bolting, riveting or welding require lapping the members over each other or the use of internal (and external) connecting straps, strips or other parts. Nailing for small-boat structures of wood is no longer favoured because of the difficulty in making repairs. If the limitations and advantages of each of the jointing methods are kept firmly in mind, it will be found that practically every one of them serves well in some particular application on board ship.

Welding has the great advantage over riveting in that it eliminates excess metal and saves weight practically everywhere in a ship structure, sometimes as much as 10%. As a rule, the loads are transmitted from one member to another more directly, and the resulting structure is more rigid. Under heavy deformation, such as collision damage, the welded joints will hold together better than riveted connections. Under mild deformation they are less liable to leak. Welded shell plating is much smoother than riveted plating, with appreciable savings in friction and total resistance. On the other hand, poor welding is often undetected from the outside. One small flaw in an unfortunate position can initiate a major crack.

8. Structural Tests of Ships and Models.—Those who made the early strength calculations of iron ships in the 1850s and 1860s benefited from the studies and tests of I. K. Brunel and W. Fairbairn on the tubular or box-shaped bridges previously built in Great Britain. Fracture and loss of the fast, light British destroyer "Cobra" in the early 1900s led to tests of another de-

stroyer, H.M.S. "Wolf." The need for information on the behaviour of similar structures when actually loaded to the buckling or fracture point led, in 1930, to full-scale tests of the U.S. destroyers "Preston" and "Bruce" and, later, of the British destroyer "Albuera." These tests confirmed the use of the simple beam theory for large, thin, box-shaped structures, and indicated the relative effectiveness of stiffened and unstiffened material and the rigidity of riveted joints.

Fractures of welded ship hulls during the early 1940s led to a new series of extensive structural-testing programs by Great Britain and the United States on full-size ships, including tests with various load distributions in calm water.

Beginning with the German M.S. "San Francisco" in 1934, a number of ships have been instrumented to determine in heavy seaways the wave profile along the ship's side, the water pressures and accelerations resulting from ship motion, the deflection of the ship girder and the simultaneous strains in many parts of the ship structure.

After the 1920s the techniques of making and testing structural models vastly improved. The availability, after the 1940s, of the wire-resistance strain gauge, with its small size and tiny wires cemented to the metal, made possible the testing and structural analysis of models (and ships) under high-speed dynamic loads such as impacts and shocks from underwater explosions.

IX. LAWS AND REGULATIONS FOR SAFETY

Certain safety requirements have been imposed upon the normal naval architectural requirements by law, by official regulations and by international convention. These cover a wide field, involving health, hygiene, fire protection, lifesaving and communications (radio and radar) as well as seasonal loading, watertight integrity, freeboard, subdivision and other provisions to ensure that ships will remain upright and afloat. Provision for freeboard, subdivision and other major items in the present category must be made in the original layout and arrangement sketches as part of the preliminary design.

1. Freeboard.—Aside from providing reserve buoyancy when rolling and pitching and keeping the upper decks free from green water and spray, freeboard is required to keep those decks above water when the hull is partly flooded. Adequate freeboard for running in waves must be larger in proportion to its length for a small ship than for a large one, because short waves are steeper than long ones. Freeboard must increase as the ship speed increases because of the greater pitching at higher speeds.

2. Subdivision and Floodable Length.—Subdivision by watertight bulkheads is necessary to prevent extensive flooding after only local damage. A well-designed ship should, with some damage and moderate flooding, still be able to move, steer and stay afloat. In recognition of this premise the major maritime nations of the world have approved international treaties and drafted rules specifying the minimum amount of freeboard and the extent of transverse watertight subdivision.

This subdivision is expressed as a function of the floodable length of a ship. A convenient method of relating floodable length to the ship is by a floodable-length curve. The curve is plotted on the profile of the ship so that the vertical ordinate at each point equals the portion of the ship length, centred at that point, which can be flooded without immersing a margin line. The margin line is parallel to the uppermost deck to which the transverse watertight bulkheads extend and is several inches below it, so that in calm water the ship can sink to this line without water leaking or flooding into other compartments.

When plotting the floodable-length curve, allowance is made for trim but not for heel since the ship is assumed to be open to the sea from side to side. The curve is used by the naval architect to help him decide where to place the transverse watertight bulkheads so they may be most effective in restricting the extent of flooding after damage.

The amount of water that can enter any compartment depends upon the ratio of the open-space volume to the total volume, known as its permeability. An empty hold can take nearly its entire volume of water, with a permeability of say 98%. If filled with coal, its permeability may be 20% or less.

3. Situation After Damage.—Any heel after damage makes a ship vulnerable. Excessive heel may be disastrous, as it was for the "Andrea Doria" in 1956. In a well-designed ship, subdivision is planned to ensure that the ship remains upright, or nearly so, no matter where it is opened to the sea, or that heel can be corrected by counterflooding on the opposite side. Unless the flooding occurs amidships, the ship trims by the bow or stern. This may render it vulnerable in a heavy sea. Compartments at the ends are usually shorter than those nearer amidships.

Because of the intact water plane lost and the free surface in the flooded areas, the partly flooded ship almost invariably loses some transverse metacentric stability. Such a ship can survive if somehow it can be kept upright. Several ships bombed in the 1940s were saved by lashing them to adjacent piers and other craft to hold them upright until they could be pumped out.

X. SHIP DESIGN PROCEDURE

The work outlined in the foregoing, together with other tasks depending upon the type and mission of the ship, is carried out in several definite stages, indicated by the following headings.

1. Preparation of Requirements.—When the operator decides a new ship is needed he prepares an outline of the desired requirements, often with the technical advice of a professional ship designer. The latter endeavours to embody in the specifications many features requiring decisions to be made by the owner. Settling them early avoids interruptions and delays at later stages. If these decisions are not readily made, a number of preliminary designs may be worked up to indicate the range of possibilities within the limits tentatively established by the operator. The latter is then in a better position to make his decision, or to require that further sketch designs be prepared.

2. Compromises Necessary.—A layout of the proposed ship is no sooner begun than the naval architect encounters limitations on every side. If the ship is made large enough to house all the necessary components conveniently, it becomes too large, too costly to build and consumes too much fuel. If held to a moderate size, cramping, squeezing and overlapping begin as the components are worked into the arrangement plan. The mission of the ship must constantly be kept in mind as space and facilities are pared here and there. To carry out this give-and-take process intelligently and logically, the naval architect must have a fundamental and general knowledge of all aspects of the design and an intimate knowledge of all features mentioned in this article.

Imperfect knowledge of physical laws relating to ships and their behaviour forces the naval architect to rely heavily on experimental data, empirical rules and past experience. This situation is aggravated when, as frequently occurs, he is forced to apply trial-and-error methods to certain features of the design.

3. Preliminary Design Stage.—The purpose of the preliminary stage is to present to the prospective owner one or more designs which represent a feasible and economical fulfillment of the requirements. Usually only the major features of the ship are worked out at this stage. However, an extensive knowledge of the details of ship design is called for to determine the effect of the minor features without actually designing them.

As the first step in this stage, the naval architect chooses the ship type and its size. Usually a number of existing vessels meet roughly the requirements he is trying to fulfill. With these as guides he selects combinations of hull type, machinery and structural material to form one or more parent or basic types. At other times he is faced with most unusual requirements and with design problems that appear to be entirely new to the profession. Here he must start from the beginning, with his experience, knowledge and judgment as his principal guides.

Following the roughing out of the design in small-scale sketches, the major features of the ship are laid out in three types of drawings. The general arrangement drawings show the arrangement of spaces and equipment in profile elevations and deck plans (fig. 5). The line drawings depict the external shape of the underwater and above-water hulls. This is delineated by intersections of the hull with three series of planes at right angles to each other. The

structural arrangement drawings embody midship sections such as fig. 13, 14, 15 and 16, together with typical sections at other stations and drawings showing other general features of the structural configuration and the principal scantlings. The latter are based upon a preliminary calculation of longitudinal strength (see *Strength of Ships*, above).

In preparing these drawings the naval architect must determine whether each design proposal satisfies the performance and naval architectural requirements. Based on this and a weight study, the stability can be checked.

When the preliminary design studies have been carried as far on paper as existing knowledge permits, especially with respect to the power needed to achieve the given speed, one or more models are built. These models are towed and then self-propelled with a stock propeller (many of which are available at most model basins) to determine more accurately the ship's resistance and required propulsive power. Additional data can be obtained during these and other tests, concerning the nature of the flow into the propeller position, to enable the naval architect to design a final propeller, provided the hull shape and loading conditions are not changed in the meantime.

4. Contract Design Stage.—When a preliminary design appears to give promise of a ship that will meet all the requirements to everyone's satisfaction, the naval architect proceeds with the preparation of contract plans. These are intended to be sufficiently complete and comprehensive to enable the shipbuilders to make estimates of cost and time of construction. When combined with the detail specifications, prepared concurrently by the naval architect, there is enough information at hand to enable the successful bidder to draw the working plans, fabricate the parts and build the ship in accordance with the wishes of the prospective owner and the naval architect.

The preliminary lines, general arrangement and structural plans are drawn to a large scale and in more detail. Accompanying these are diagrammatic and arrangement plans of the main propelling and auxiliary machinery or of other major features in this category, such as the pumping machinery on a dredge or on a fireboat, prepared by marine and mechanical engineers. Calculations for strength and metacentric stability and the weight estimate are also expanded and done with more precision. Diagrammatic plans of cargo-handling arrangements, hull piping, ventilation and air-conditioning systems are prepared. Similar plans are drawn for the electrical systems and for location of the electronic equipment. The detail specifications cover particular features and characteristics of all components of the ship which cannot conveniently be shown on the plans.

The preparation of working drawings to be used by the artisans and mechanics in the shipyard is a phase of shipbuilding and is not discussed here. *See* SHIPBUILDING.

NAVAL AVIATION: *see* AIR POWER.

NAVAL STORES, a term that originally designated the pitch, tar, resin, flax, cordage, masts and timber used in building and maintaining wooden sailing ships but is now applied only to the products of the pine tree. These products fall into two groups: gum naval stores derived from the oleoresin (gum or pitch) of the living pine, commonly called crude turpentine, and wood naval stores obtained by processing dead pine wood.

The United States is the foremost producer of naval stores, with France ranking second. Large amounts also come from Greece, Spain, Portugal and Mexico. Pines planted in the maritime provinces of France by order of Napoleon I as a measure to control the sand dunes are the profitable source of French naval stores, its constancy assured by careful forestry. In the U.S. the industry is centred in the south, where longleaf and slash pines abound.

The raw material of the gum naval stores industry, oleoresin, is a semifluid substance composed of resins dissolved in turpentine oil, its chief component being pinene. It is extracted from the pine by cutting through the sapwood into the heartwood of the tree (where resins accumulate) and collecting the exudate that issues from the wound. Formerly, gum was obtained by cutting a recess or box into the pine at its base and collecting the gum in a cup placed at the point of a V-shaped gash in the rear wall of the recess. Each tapping of the tree required the cutting of a new gash, leaving a succession of scars on the tree's heartwood. Boxing was destructive of tree life, many trees surviving this treatment by only a year or two. It has given way to a wiser shallow cutting with which narrow metal gutters are employed to channel the gum into collecting cups. It has been found that an application of sulfuric acid to a fresh cut induces a fuller and more prolonged gum flow, with the result that the turpentine yield is materially increased.

Turpentine is extracted from oleoresin by distillation; the residual compounds harden into the substance known as rosin. The individual farm still was once essential to the processing of gum. The farm operation consisted of subjecting the gum to heat in a brick-supported copper pot heated by a wood fire. Turpentine and water vapour were condensed in the water-cooled copper pipes of the still, and the liquid material was discharged into a container where it quickly separated into two layers with the turpentine on top. Remaining in the still was the molten rosin, combined with dirt, sand, bark, pine needles and such other foreign matter as had escaped the occasional skimmings of the pot. Although the rosin was strained through wire mesh and cotton batting, it proved upon hardening to be impure and was dark in colour.

The farm still has largely yielded to the large central cleaning and distilling plant where the gum is freed of foreign bodies by thorough washing and filtering. From cleansed and purified gum, after the extraction of turpentine by steam distillation, a pure, translucent, pale amber rosin is produced.

Wood naval stores are derived from salvaged pine wood, such as tree stumps and "downwood" or lightwood—pine from which the bark and sapwood have fallen away in decay. Although methods of treating the wood vary, generally it is shredded and subjected to heat under pressure in a digester. The volatile components—carried off, condensed and refined by fractional distillation—yield wood turpentine and pine oil, the latter product unobtainable from the oleoresin of the living tree. The residual resin retained in the shredded wood is extracted by treatment with a mineral oil solvent. The resulting resinous solution, purified and relieved of solvent by vaporization, gives wood rosin.

Sulfate wood turpentine, a by-product of the sulfate method of making pulpwood paper, is obtained by condensing the vapour from the digester in which the wood is treated. The turpentine, seriously contaminated by sulfur compounds, is purified by chemical treatment and fractional distillation. Although no rosin is recoverable in this pulping operation, the cooking liquor used in the process may be salvaged and treated chemically to yield the useful mixture of resinous and fatty acids known as tall oil.

NAVAN (AN UAIMH), an urban district and the county town of County Meath, Republic of Ireland, is situated at the junction of the rivers Boyne and Blackwater almost in the centre of the county and 30 mi. N.W. of Dublin by road. Pop. (1961) 3,998. The Great Mote, an imposing earthwork (52 ft. high), is on its western outskirts. The town was walled and fortified by Hugh de Lacy and grew to considerable importance during the English settlement. Later it became a defense outpost of the English pale. Its official name, An Uaimh, means "the grotto" or "the cave." A shopping and market centre, it also has manufactures of furniture, carpets and woolen goods. About 1½ mi. N.E. is Donaghmore with slight remains of a 13th-century church that succeeded a Celtic church said to be associated with St. Cassanus, a disciple of St. Patrick. A round tower (100 ft. high), which was probably

built in the 10th century at the time of the Norse invasions, survives; an unusual crucifixion scene is carved above its doorway. About 8 mi. N.W. of Navan is Teltown hill, site of an ancient royal residence (one of four built by King Tuathal), where the Aonach Tailteann (Olympic games of Ireland) were held from about 1420 B.C. until the death of Roderic (Rory O'Connor) in A.D. 1198.

(W. M. Po.)

NAVARINO, BATTLE OF (Oct. 20, 1827), one of the decisive events of the War of Greek Independence. It was the unexpected outcome of the treaty of London of July 6, 1827, providing for British, Russian and French intervention in the Turkish-Greek conflict. Assuming that the Greeks would accept and the Turks refuse an armistice, the powers instructed their naval commanders to intercept Turkish supplies. They envisaged a mere demonstration. But before the allied squadrons were united, an Egyptian fleet slipped into Navarino bay (the ancient Bay of Pylos in the southwest of the Peloponnese) on Sept. 9, there joining a Turkish squadron. Sir Edward Codrington, the British admiral, arrived off Navarino on Sept. 12. On Sept. 25 he and the French commander, Rear Adm. Comte Henri Gauthier de Rigny, held a conference with Ibrahim Pasha, the commander of the Turkish-Egyptian forces. Believing that Ibrahim had promised to cease hostilities until couriers could bring definite instructions from Constantinople, they left Navarino, intending to return on Oct. 14. Ibrahim had understood that the Greeks would cease fighting; but on hearing that Gen. Sir Richard Church, commander in chief of the Greek forces, was threatening Patras, he sent two squadrons northward toward that gulf. Shots fired by Codrington caused these to return to Navarino on Oct. 7. Codrington, asserting that bad weather prevented their keeping watch outside, persuaded his colleagues (the Russian squadron under Adm. L. P. Heiden arrived on Oct. 17) to enter the bay. Ibrahim's couriers had not returned, but he had just received a letter of Aug. 20 imploring him to fight. His ships (89 sail, 2,240 guns) were in an arc, three deep, across the bay. The allied entry on Oct. 20 (with 27 ships, 1,324 guns) was hazardous, for Ibrahim probably intended after nightfall to attack with fireships. Certain Egyptians moved a fireship prematurely and fired on a boat ordering them to desist. The action, lasting four hours, soon became general. Finally 60 Muslim vessels were sunk, and 8,000 Muslims were killed. No allied ships were lost, but 176 officers and men were killed. *See* also GREEK INDEPENDENCE, WAR OF.

See G. Douin, *Navarin: 6 juillet–20 octobre 1827* (1927).

(D. DN.)

NAVARRE (NAVARRA), a province of northern Spain. Area 4,023 sq.mi.; pop. (1960) 402,042; population density 99 per sq.mi. Originally formed by the Basques into a kingdom in the 9th century, it was not annexed to the Spanish crown until 1512 (*see* NAVARRE, KINGDOM OF). Under the Nationalist government it enjoyed a limited economic autonomy. In the remote districts Lower and Upper Navarrese (Basque subdialects) and Navarro (Aragonese dialect) are still spoken. Navarre is bounded by the French Pyrenees to the north, Guipúzcoa province to the northwest, Álava and Logroño to the west, Zaragoza (Saragossa) to the south and southeast and by the Aragonese province of Huesca to the east.

Navarre has a great variety of scenery as it stretches from the western Pyrenees to the Ebro steppes. A tripartite division is clear: the Pyrenean sector; the central basins and hills; the southern plateaus and steppes. North of a line drawn through the Araquil valley and the foothills that overlook the basins of Pamplona, Aoíz and Roncal, the Pyrenean sector consists of a tangled relief of forested mountains and well-watered valleys. The ranges consist largely of sandstones with rounded and more subdued relief (seldom exceeding 4,000 ft.) than the central Pyrenees. The chief Pyrenean road pass is the Col de Roncesvalles (Puerto de Ibañeta; 3,468 ft.), with two others to the northwest, the Puertos de Maya (Otsondo) and de Vera. The region is largely drained by the Bidasoa, an Atlantic stream. The lower basin, called Cinco Villas, has a relatively dense population in scattered hamlets. Iron workings have encouraged small metallurgical industries at Vera and Elizondo, linked by a narrow-gauge railway to Irún; but the dense stands of timber and pastoralism are the main sources of wealth.

The central depression, now utilized by the railway from Vitoria to Pamplona and then by a narrow-gauge line to Sangüesa on the Aragón river, has played a vital role in Navarrese history. It has united the diverse Pyrenean valleys and focused commerce on the provincial capital, Pamplona (*q.v.*). In this climatically transitional zone, cereal cultivation mingles with forest lands and stock rearing, and settlements become more nucleated into villages.

The southern half of Navarre consists essentially of foothills and steppes through which the valleys of the Ega, Arga and Aragón run centripetally to the Ebro. The position of Tudela (pop. [1960] 16,456) near the confluence of these valleys explains its role as a regional market town. The landscape is more arid and monotonous with cultivation of cereals, and large nucleated settlements, *e.g.*, Estella (8,236) and Tafalla (7,320). Las Bárdenas on the southeastern borders is true steppe. (J. M. Ho.)

NAVARRE, KINGDOM OF, a former independent kingdom of Spain (known until the last half of the 12th century as the KINGDOM OF PAMPLONA, after its capital and chief city) which, at the time it ceased to exist as such (1512), occupied the area of the present province of Navarre (Navarra) (about 4,000 sq.mi.) together with the Tierra de Allién Puertos, on the northern approaches to the pass of Roncesvalles. This was a small region between Labourd and Béarn whose capital was at St. Jean-Pied-de-Port. In the middle ages much of Navarre was Basque-speaking. The other language used was the Navarro-Aragonese dialect, which, together with French (after 1234), was the language of the administration. The whole kingdom was mountainous except for the Tudela salient in the southeast, where the dry plains called Las Bárdenas provided an important grazing region. Though Navarre at an early date ceased to have a frontier with the Moors, a considerable Moorish population lived there, notably in Tudela. The Navarrese Moors were allowed to serve in the army, and also provided an important source of skilled artisans. Large Jewish *aljamas* (congregations) existed in the chief towns and were protected by the Navarrese kings when persecution became serious elsewhere. Another important element were the *francos*—mostly French and Gascon immigrants—who inhabited separate quarters in Pamplona and other towns. Their relations with the native Navarrese population were often strained.

Despite its small size in the later middle ages, Navarre's part in international politics was important, not only because of its rulers' involvement in French affairs but also because it controlled the main pass into Spain in the western Pyrenees and was a buffer state between Gascony, Castile and Aragon. The chief pilgrim roads from the north to Santiago de Compostela thus traversed it. From its earliest days to 1234, after which a succession of French dynasties ruled Navarre, the kingdom's history fell within a wholly Spanish context and was closely associated with that of Aragon. Afterward strong French political and institutional influences can be detected.

Pamplona was Moorish territory after 711, but the Basque magnates of the region early achieved some degree of autonomy and (*c.* 798) one of them, Iñigo Arista, established himself as an independent ruler there and, for a time, accepted Frankish suzerainty. By the time of García Iñiguez (*c.* 860–880) this dynasty was strong enough to assume regal titles and to establish diplomatic and family relations with Asturias. Under Sancho Garcés (905–925) the rulers of Pamplona extended their dominions south of the Ebro, capturing Nájera and much of La Rioja. By a combination of diplomatic dexterity and military strength the kingdom survived, relatively unscathed, the heyday of the caliphate in the 10th century. During the reign of Sancho III the Great (1005–35), the Navarrese were able to establish a brief hegemony over all Christian Spain. Sancho's empire was, however, short-lived and in 1076 Sancho Ramírez of Aragon (1063–94) occupied Pamplona.

Until 1134 Navarre was then ruled by the Aragonese crown. It recovered its independence when the Navarrese proclaimed García V, "the Restorer" (1134–50), as king (*see* GARCÍA). An entirely new orientation was given to Navarrese history in 1234 when Sancho VII (1194–1234) was succeeded by his nephew, Theobald I

(1234–53), count of Champagne, and a succession of French rulers with important possessions in France ruled the kingdom. They included, at times, the kings of France themselves. Historically the most famous of these French rulers was Charles II (*q.v.*) "the Bad" (1349–87), count of Évreux, under whom Navarre became internationally of great importance because of the king's involvement in French politics and the spread of the Hundred Years' War to the kingdoms of the Iberian peninsula. Charles himself had ambitions to recover for his kingdom the territories in Spain which had belonged to Sancho the Great. He has been severely criticized for the brazen way in which he constantly altered Navarrese foreign policy to meet rapidly changing foreign pressures. Charles managed, however, to retain the loyalty of his subjects and to preserve the independence of Navarre, though he lost all his French possessions except Allién Puertos and (1379) had to accept Castilian garrisons in his southern castles.

The reign of Charles III (*q.v.;* 1387–1425) was relatively tranquil, but John II of Aragon (*see* JOHN, kings of Aragon) became ruler of Navarre by marriage (1425–79) and the kingdom was then the scene, for years, of civil war between his supporters, those of his son and heir, Charles, prince of Viana, and other factions favouring union with France or with Castile. In 1484 the throne passed to John II of Albret, but independence had now become impossible on account of Navarre's position between two major and mutually hostile states, France and Spain. In 1512 Ferdinand the Catholic occupied the Spanish portion of Navarre. In 1515 the country was formally annexed to the Castilian crown but retained its status, institutions and law as an independent kingdom until the 19th century; it, as a province, still preserves its own civil administration and law.

In the later middle ages Navarre was divided administratively into five *merindades*—La Ribera (Tudela), Sangüesa, Pamplona (La Montaña), Estella and Allién Puertos; in the last the functions of royal *merino* were carried out by the *castelán* of St. Jean-Pied-de-Port. Under the *merinos* were the *sozmerinos* and, in the towns, the *bailes.* The chief military officer of the kingdom was the *alférez.* The treasury (*cámara de comptos*) was partly modeled on the French system under a *recibidor general* or *tesorero*, with *recibidores* in each *merindad.* The somewhat ambiguous international status of Navarre was reflected in its coinage; apart from local currency, French, Gascon and Aragonese money circulated freely. The law of the land was based on the *Fuero General de Navarra* (a body of customary law built up before 1155) but much modified in different localities by local *fueros.* Efforts by some of Navarre's French rulers to undermine customary law were strongly and effectively resisted, though feudal grants sometimes appear. In the 14th century one-sixth of the whole population claimed *hidalguía* (noble descent) and the tax exemption which went with it. The *Corte General* of Navarre controlled, in theory, not only extraordinary subsidies (*pedidos*) but also ordinary taxation. Since, however, it was the king's prerogative to decide who should be summoned, and when, the Navarrese parliament had little real power and its legislative importance was slight. Ecclesiastical jurisdiction in Navarre was complicated, the bishops of Dax and Bayonne (in Gascony), Tarazona (Aragon) and Calahorra (Castile) having, or claiming, authority over outlying regions. Shortage of man power was a constant concern from a military point of view; the earliest *fueros* had not contemplated the existence of a formal army at all. Later the defense of the kingdom rested on a large number of small castles. To increase reserves in war the later kings (notably Charles II) enlisted large numbers of foreign knights and their retinues as *mesnaderos;* these, in return for an annual pension, undertook to serve in Navarre when summoned. Navarrese culture in the late middle ages was much influenced by the pilgrim route, and French influences were naturally predominant.

NAVARRETE, JUAN FERNÁNDEZ: *see* FERNÁNDEZ NAVARRETE, JUAN.

NAVARRO, PEDRO (*c.* 1460–1528), Spanish soldier of fortune, the foremost military engineer of his time. The details of his birth (probably at Garde in the Navarrese valley of Roncal) and of his early career are uncertain; he is thought to have been a *condottiere* in Italy and to have operated in the Mediterranean against the Barbary pirates. Enlisted by Gonzalo (*q.v.*) de Córdoba in 1499, he went with the latter's expedition from Spain to Cephalonia in 1500 and breached the walls of the Turkish stronghold with his mines. He next followed Gonzalo to the conquest of Naples (1501). As war soon ensued between the Spaniards and their French partners in that conquest, he played a distinguished role in Gonzalo's victory at Cerignola (1503); and the success of his mines against the French-held fortresses won him international fame. Ferdinand II of Aragon rewarded him with the Neapolitan countship of Oliveto, in the Abruzzi mountains.

Having returned to Spain in 1507, Navarro won further glory in expeditions against the Barbary states. A floating battery designed by him was instrumental in the capture of Vélez de la Gomera (1508); he took part in the capture of Oran (1509); and he was commander in chief in the conquest of Tripoli (1510).

In the war of Pope Julius II's Holy league against the French in Italy, Navarro, in command of the Spanish infantry, fell into French hands at the battle of Ravenna (1512). Since Ferdinand of Aragon would not ransom him, he finally entered the service of Francis I of France and fought for him in the Milanese campaign of 1515–16 (*see* MARIGNANO, BATTLE OF). War having broken out between Francis and the Holy Roman emperor Charles V in 1521, Navarro was captured by the emperor's forces at Genoa after the battle of La Bicocca (1522). Released under the short-lived treaty of Madrid (1526), he accompanied the French expedition of 1527 to Italy and was again taken prisoner—to die in the Neapolitan fortress of Castelnuovo in 1528.

NAVE, in architecture, is the central and principal part of a church, extending from the main front to the transepts, or to the

A. F. KERSTING

NAVE OF SALISBURY CATHEDRAL, ENGLAND, 1220–65

choir or chancel (*q.v.*) in the absence of transepts. When the nave is flanked by aisles, light is admitted to the church through clerestory windows. (*See* ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE.) At times, a gallery was carried above the side aisles.

Ecclesiastically considered, the nave is that part of a church appropriated to the laity as distinguished from the chancel, the choir or the presbytery, reserved for the clergy. In a 14th-century letter (quoted in Gasquet's *Parish Life in Medieval England*, p. 45, 1906) from a bishop of Coventry and Lichfield to one of his clergy, the reason for this appropriation is given. "Not only the decrees of the holy fathers but the approved existing customs of the Church order that the place in which the clerks sing and serve God according to their offices be divided by screens from that in which the laity devoutly pray. In this way the nave of the church . . . is alone to be open to lay people, in order that, in the time of divine service, clerics be not mixed up with lay people, and more especially with women, nor have communication with them, for in this way devotion may be easily diminished."

NAVEL, in anatomy, the umbilicus, the depression in the abdomen which indicates the point through which the mammalian fetus obtained nourishment from its mother through the blood vessels of the umbilical cord.

See EMBRYOLOGY AND DEVELOPMENT, ANIMAL: *Human Development;* PLACENTA.

NAVIES, EARLY HISTORY OF. The term navy originally meant the whole of a country's shipping, whether used for war, the carrying of merchandise or fishing. In modern parlance, however, the word is generally taken to mean a nation's warships and craft of every kind maintained for fighting, and the personnel manning them. It includes cruisers, aircraft carriers, destroyers, mine layers, mine sweepers, gunboats and other auxiliary craft; the submarines; and the fleet air arm. Behind the actual fighting units there is, necessarily, a vast organization for their administration and upkeep.

See the sections *Defense* of the articles UNITED STATES (OF AMERICA); FRANCE; GERMANY and other countries for the modern history of naval establishments; *see* also NAVAL AFFAIRS (ARTICLES ON).

In early history navies took the form of the armed men of a tribe or town putting to sea in such large boats or ships as might be available to give battle to enemies similarly equipped or to raid territory from the sea. The craft themselves were for the most part those used for commerce, fishing or, when occasion served, for war or piracy. Only exceptionally were they built specifically for fighting. Special types of war craft appeared later. There are definite indications of long ships built for speed as distinguished from round ships for burden from the time of the ancient Greeks and Romans. In 483 B.C. the threat of Persian attack caused Athens to increase its fleet from 50 to 100 long ships which were paid for out of the proceeds of the mines of Laurium (*see* THEMISTOCLES). The effect of this was to make Athens the predominant partner in the league formed by the Greeks for their common naval defense. By the end of the 5th century B.C. the fleet had increased to 300 long ships and later to as many as 360. In peace these war vessels were kept on slips and under cover in sheds; in war a *strategos* was appointed in command and he chose the trierarchs who were deputed to commission the vessels, partly at their own expense, under the supervision of state inspectors.

In general the organization of the Athenian navy resembled closely that of the British navy in the 16th and 17th centuries. The trierarch, who was either one of a group of citizens assisting to finance one or more war vessels or someone paid to discharge the duty, answered to the captain. There were also sailing masters, petty officers, seamen and oarsmen. Soldiers or marines formed the fighting personnel. The most ancient warships were many-oared galleys (*q.v.*), each requiring a very large number of rowers. The result was that the personnel provided to man a fleet of those times had to be a considerable one. For instance, the Roman and Carthaginian forces in the first Punic War numbered approximately 150,000 men on each side. The great rowing galleys relied for their offensive powers on boarding or ramming, and they appeared in great numbers in the Mediterranean in the war fleets of Alexander, of Carthage, of Rome, of Byzantium, of the Italian republics, of the Arabs and of Aragon. (*See* also SHIP.)

In the naval organization of ancient Rome can be seen the beginning of the idea of an admiralty in the navy commissioners appointed in 311 B.C. It is interesting to note, too, that the Roman empire was faced, on a small scale, with the same kind of maritime problems that assumed such vast importance for the British government in the 19th century. Rome maintained a fleet to neutralize the threat arising from rival sea powers and to deal with pirates and protect its trade routes. Its naval organization, which was very complete, included two main fleets which guarded the coasts of Italy at Ravenna and Misenum. These were known as the praetorian. Other squadrons were allocated to Forum Julii, to the mouth of the Orontes, to Alexandria, to Karpathos (between Crete and Rhodes), to Aquileia (at the head of the Adriatic), to the Black sea and to Britain. River flotillas were stationed on the Rhine and Danube and, later, on the Euphrates. All these squadrons did not exist at the same time, but there was always a highly organized navy with a body of soldiers, the *classici*, specially assigned for service afloat.

The navy of the eastern empire may be said to have originated with the foundation of Constantine's New Rome on the site of Byzantium. The threat of attack from the Vandal kingdom of Carthage (from A.D. 428 to 524) compelled the emperors to attend to their fleet, but with the fall of that kingdom the navy was neglected until the rise of Islamic power at the end of the 7th century produced a new menace. The Byzantine navy reached a high state of efficiency under the sovereigns of the Macedonian dynasty (867–1056). It consisted of an imperial fleet commanded by the great *drungarios*, the first recorded lord high admiral, and of provincial squadrons under their *strategoi*. The imperial fleet was essentially a war organization, while the provincial or thematic squadrons were smaller but more permanent forces maintained for police purposes. It is interesting to note that this navy included a corps corresponding to the gunnery experts of a modern fleet. These were the *siphonarioi*, who worked the siphons used for discharging the Greek fire (*q.v.*).

After the disorganization of the eastern empire by Turkish invasions in the 12th century, the Byzantine navy withered. In the middle ages the Italian republics and monarchial states bordering on the Mediterranean possessed appreciable fleets, and their seamen, especially those of Genoa, were regarded as some of the finest in the world, so much so that their services were sought by the powers of western Europe and even by England. Edward III and the kings of France employed Genoese to assist them in nautical matters. The Mediterranean navies made their last great appearance in history at the battle of Lepanto, 1571 (*q.v.*). The scene then changed and the ships and fleets took on a new form—one to fit them for ocean sailing and fighting. (E. A.; X.)

NAVIGATION, the process of conducting a craft from one place to another. In its widest sense the word thus embraces not only finding the way but also the avoidance of collision and the handling of the craft. The processes of navigation in general consist in defining the route, conducting the craft along it and finding the craft's position from time to time to check its progress.

The most common way of defining direction on the earth is in relation to its axis of rotation. Position on the earth's surface, or at points close to the surface, is usually expressed in terms of latitude and longitude. Position may be established by dead reckoning (the accounting of distance and direction traveled) or by independent fixes which establish that the craft lies along one or more lines of position. Methods of fixing used at sea and in the air today include visual fixes, astronomical navigation, radio systems and radar. Dead-reckoning methods include the compass

and distance or speed indicators of one kind or another, inertial guidance systems and systems making use of the Doppler shift.

The methods of navigation used by the ancients can be deduced from fragmentary evidence in literature, even though there are large gaps in our knowledge. Modern navigation, both at sea and in the air, relies more and more upon mechanical and electronic devices, even though the human intelligence remains as a vital link. In outer space, navigation is likely to be done solely by nonhuman means.

I. HISTORICAL BACKGROUND

Ocean voyages well out of sight of land have been made for thousands of years in every civilization. The Minoans, for example, carried on a regular trade between Crete and Egypt and built the port of Cnossus especially for it. The Phoenicians were trading to Cornwall for tin in about 600 B.C., and 1,200 years later the Vikings were making regular journeys across the Atlantic to their settlements in Greenland and North America. There is thus no evidence for the popular supposition that all early navigators clung to the coast.

Exactly how the earliest navigators found their way must remain to some extent a matter of conjecture, but we know enough to reconstruct some of their methods. Herodotus, for example, tells us that the Phoenicians used Polaris (the pole star) to find direction. Homer has the wise goddess bid Odysseus keep Ursa Major (the Great Bear) on his left hand as he crosses the sea after leaving Calypso's island. In the Acts of the Apostles and in some of the early Norse sagas there are passages that make it clear that the sun and stars were used as guides.

Divisions of the Horizon.—North, south, east and west have always been defined by sunrise and sunset and by the direction of the sun's noonday shadow. The apparent rotation of stars around the north pole of the sky, too, would have been familiar to seamen and others whose calling involved a knowledge of direction. The division of the horizon into more than these four basic directions first seems to have been made by the Greeks, who differentiated between the directions of sunrise and sunset in winter and summer, a difference of about 30° in those latitudes. For reasons of symmetry, no doubt, they also defined directions on either side of the north–south line corresponding to the lines each side of east and west, and so the twelvefold compass of classical antiquity developed. The Tower of the Winds at Athens, however, shows eight winds, and it seems more probable that seamen from the earliest times accepted this division based simply on dividing and subdividing the four basic directions. The Anglo-Saxons, for example, distinguished 8 "points," and the Portuguese in the great age of discovery abandoned the age-old Mediterranean wind rose, probably of Etruscan origin, for a 16-point system.

Early Sailing Directions.—All directions long were thought of as winds, and early pilot books give the courses between ports in these terms. Distances are given in terms of a day's sail. The earliest surviving pilot book is the *Periplous of Scylax,* which dates from about 350 B.C. These directions, which were the first aids to navigation, describe routes, headlands, landmarks, anchorages, currents, port entrances, etc. No doubt the information was originally handed down from father to son, as it is in some Arab lands today. It seems improbable that any sort of sea chart was used with these sailing directions, even though maps go back to the Alexandrian Greeks. Not until the advent of the magnetic compass was the construction of an accurate sea chart possible.

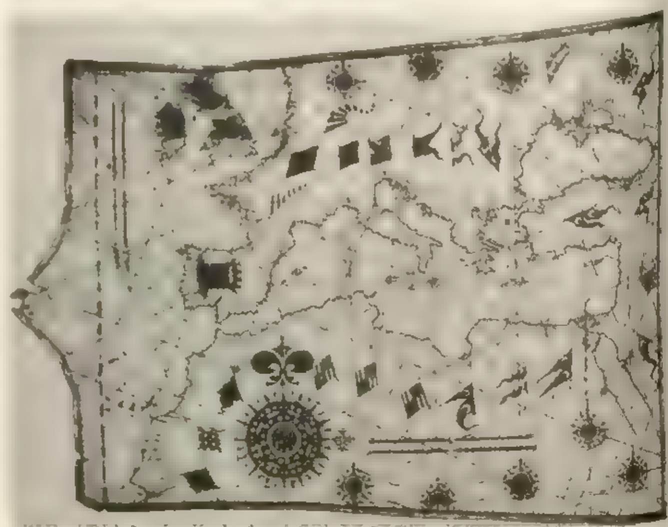
A passage from a book of sailing directions for the Arabian sea, originally written in Sanskrit in A.D. 424, gives an illuminating description of navigation before the days of chart and compass: "The pilot," it says, "knows the course of the stars and can always orient himself; he can evaluate the signs of good and bad weather; he distinguishes the regions of the oceans by the fish, the colour of the water, the nature of the bottom, and birds, the mountains and other indications."

The distance traveled was deduced from the speed. The first method of measuring speed was by timing the passage of a chip of wood (hence "log") dropped from the stem until it passed the poop. Later a triangular piece of wood, known as the log ship, was attached to a line payed over the stern from a reel, the amount of line that ran out in a given time showing the speed. Timing was first done by such devices as repeating syllables and counting the pulse, but later the sandglass was introduced, a 28-second glass being used for speeds up to 6 knots and a 14-second glass for speeds above that. The first suggestion that the line should be knotted (hence "knot") seems to have been made by Richard Norwood in 1637. Knots at 51-ft. intervals were used with the 28-second glass.

The Magnetic Compass.—The birthplace of the magnetic compass is sometimes disputed. The first written reference to the use of the magnetic needle for direction finding at sea seems to have been made by an Englishman, Alexander Neckam, writing in 1180. He speaks of "a needle placed upon a dart which sailors use to steer by when the Bear is hidden by clouds." Writing about 80 years later, a Dominican friar, Vincent of Beauvais, tells how seamen, when they can no longer see sun or stars to steer by, magnetize the needle with a loadstone and place it through a straw floating in water. The needle comes to rest, he says, pointing at the pole star.

The compass card, with its painted wind rose displaying the division of the horizon, was probably first attached to the needle in the 13th century. So familiar has this combination become that it is customary to think of the compass as the instrument itself, whereas the word originally meant merely the division of the horizon.

Later Sailing Directions.—The earliest surviving set of Mediterranean sailing directions, *Lo Compasso da Navigare* (1296), talks in terms of half points, that is, $\frac{1}{64}$ of the compass of the horizon. It was from such directions, accumulated over generations and then collected during the 13th century into a single



BY COURTESY OF THE TRUSTEES OF THE NATIONAL MARITIME MUSEUM, GREENWICH, LONDON

FIG. 1.—PORTOLAN CHART OF THE MEDITERRANEAN BASED ON RHUMB LINES, ASCRIBED TO SIMON FERNANDEZ, 16TH CENTURY

volume for the entire Mediterranean, that the first marine chart was drawn. This chart, the famous Carta Pisana, was drawn on sheepskin and is oriented toward the Stella Maris rather than Jerusalem (as most land maps were). It carried a scale of miles and a pattern of rhumb lines distinguished by coloured inks.

corresponding to the directions shown on the wind rose. To set a course on such a chart the pilot would draw a line between his departure point and destination and then, with a pair of dividers, pick out the coloured rhumb line most nearly parallel to it; when traced back to the parent wind rose the rhumb line would show the required course.

So long as navigation was simply by dead reckoning and was restricted to that area, the Mediterranean chart, unrelated to latitude and longitude, was perfectly satisfactory. It ignored the magnetic variation (the angle at any place between true and magnetic north), but since sailing was by the magnetic needle the variation could be neglected. It also ignored (though not always through ignorance) the fact that the earth is a sphere and that any flat representation of it must somehow take into account the convergence of the meridians toward the poles. But here again no great harm was done so long as sailing was still a matter of going a certain distance on a certain rhumb of the wind or compass point.

When the Portuguese under the leadership of Prince Henry the Navigator ventured farther and farther south along the African coast, they encountered navigational difficulties because they assumed that the plain charts used in the Mediterranean could simply be extended. But over long distances the rhumb lines could not be taken as straight, and the chart proved completely inadequate to the new methods of checking the dead reckoning that Portuguese astronomers and mathematicians had devised under Prince Henry's patronage. These methods demanded a chart related to latitude and longitude, not one merely built upon bearing and distance. In 1569 Gerardus Mercator published his world map on a "true projection suitable for navigation." Thirty years later, Edward Wright provided an explanation of the projection and computed tables of meridional parts so that cartographers could make use of the principle. However, a long struggle ensued between seamen who wanted to keep the "plain," simple chart, and the enlightened few who saw that only a "true" chart could be free of errors. The struggle lasted until well into the 18th century.

The Portuguese method of position finding involved observation of the altitude of the pole star in order to determine latitude. The star was observed when it was "in rule," that is, when the position of the "guard" stars in Ursa Minor (the Little Bear) showed that the pole star, which circles around the pole of the sky, was precisely at the altitude of the pole. When the navigators approached the equator, where the star of course disappears, latitude was obtained by observations of the noonday sun.

Altitude-Measuring Instruments.—The first instrument used for these observations seems to have been the quadrant, long known to astronomers. The star is observed through pinhole sights and its altitude read off where a plumb bob cuts the scale. Later it seems to have become the practice to mark the scale of the quadrant directly with the altitude of the pole star at certain locales, such as Lisbon. The pilot could thus directly observe the latitude of his destination. The ship would sail north or south until she reached the required latitude and then go east or west to her destination, making continual latitude observations.

Columbus is often credited with having discovered the variation of the compass, but it seems improbable that the Portuguese pilots, not only in making continual observation of the pole star but also in sailing east or west along a parallel of latitude, could have failed to observe the phenomenon.

Another instrument used for measuring altitudes at sea was the mariner's astrolabe, an adaptation of the astronomer's astrolabe (*see* ASTROLABE). The instrument used at sea carried only the altitude-measuring alidade, normally fitted to the back of the astronomer's astrolabe. The central part of the instrument was cut away to lessen wind resistance.

However, the mariner's astrolabe did not achieve the popularity of its 16th-century successor, the cross-staff—a simple device consisting of a staff about three feet long fitted with a sliding crosspiece that made it possible for even an unskilled observer to measure the angle of elevation of a star or the sun. The cross-staff remained in use until the 18th century despite several drawbacks, the most serious being that the sun could be observed only by looking straight at it. Coloured shades were fitted to the crosspieces, but the major improvement came in 1594 when John Davis, a navigator famous for his Arctic explorations, invented the backstaff. This instrument, with a scale divided into two and used with the observer's back to the sun, remained popular even after the introduction of the far superior Hadley's quadrant (so called, but actually an octant). John Hadley, who was a fellow of the Royal society, described his quadrant in 1731. Its virtue lay in the use of the principle of double reflection to overcome the motion of the ship. Thomas Godfrey, a Philadelphia glassworker, independently devised a similar instrument at about the same time. The sextant, a refinement of Hadley's quadrant, followed soon afterward and is in regular use today. (*See* SEXTANT.)

Almanacs and Tables.—Working at first from knowledge derived from translations of Portuguese and Spanish manuals, a flourishing school of instrument makers, chart makers and teachers grew up in Tudor and Stuart England. They quickly improved the theory of navigation and compiled more accurate tables. One of the earliest almanacs, which also set forth the principle of determining longitude by lunar distances, was the astronomical ephemeris of Regiomontanus, published in Nürnberg in 1474. The first purely national almanac was the *Connaissance des temps*, published in Paris, which contained tables for the crude determination of longitude from the eclipses of Jupiter's satellites. In 1675 the Royal observatory was founded in Greenwich with the specific object of providing the sailor with astronomical data of the required precision. In 1753 Johann Tobias Mayer published his tables of the motion of the moon, which heralded an enormous advance.

The Marine Chronometer.—Latitude could be observed by measuring the altitude of the pole star or the sun or any star when it crossed the meridian, but the great problem remained the determination of longitude at sea. Medieval astronomers knew that longitude differences could be determined by noting the local time of an eclipse, and in the 16th century the principle of determining longitude by comparing the readings of an accurate clock with local time was pointed out. However, for seamen the problem remained unsolved. In 1714, largely because of a number of disasters due to bad navigation at sea, an act of the English parliament established the board of longitude. The board offered an award of £20,000 to anyone who could discover a method of finding out longitude within 30 mi. after a voyage of six weeks. The award was ultimately won by John Harrison, whose fourth marine chronometer, made in the form of a watch, heralded the introduction of the practice of taking timed observations of heavenly bodies at sea.

The 19th Century.—Modern methods of astronomical navigation are based on two fundamental advances made in the 19th century: the discovery of the concept of the astronomical position line by an American, Capt. Thomas H. Sumner, in 1837, and the introduction in 1875 by the French naval officer Marcq St. Hilaire of the intercept method of sight reduction.

In the 20th century, radio methods of navigation at sea and in the air, from the simple direction finder to sophisticated hyperbolic systems, largely replaced older methods of position fixing.

(M. W. RI.)

II. TECHNIQUES AND INSTRUMENTS COMMON TO MARINE AND AIR NAVIGATION

Dead reckoning (the determination of position by keeping an account of the distance and direction traveled) is common to all forms of navigation. At sea the dead-reckoning position (or "estimated position," as the position corrected for set and drift is sometimes called) is customarily maintained either by plotting with parallel rules and dividers on the chart or a special plotting sheet or by means of the traverse table which can be used to derive change of latitude and longitude for course and distance traveled. The course steered must be corrected for the effects of compass error, currents or tidal streams and drift from the wind. Distance at sea is measured by the ship's log, which records distance directly, in the case of towed logs, or speed, which may be con-

verted into distance, in the case of a pressure-type log. The magnetic compass is still standard at sea, but most large ships are fitted with a gyrocompass (*q.v.*) which indicates true north.

Various considerations render the north-seeking gyrocompass impracticable in the air, but the magnetic compass may be gyro-stabilized so that it will be unaffected by turning, acceleration and other errors. Air speed is usually measured by a differential pressure gauge that records the difference between the dynamic pressure due to the aircraft's speed and the static ambient pressure. There are a number of ways of estimating wind drift. The effect of wind on the aircraft's progress is allowed for by an application of the triangle of velocities, either by plotting or by means of a dead-reckoning computer.

The instruments used in celestial navigation are an accurate timepiece, such as a chronometer (*q.v.*) or a navigational watch used in conjunction with radio time signals, and the sextant. The marine sextant is used for measuring the altitude of a heavenly body above the visible horizon. The horizon is not normally available as a reference to the air navigator, so the air sextant is fitted with an artificial horizon in the form of a bubble that defines the vertical. To eliminate the numerous acceleration errors that affect the bubble, an integrating device that automatically averages a number of sextant observations over a run of one or two minutes is generally incorporated. Although other methods of defining a horizon in the air are in use, the bubble is the most general.

In astronomical navigation the navigator adopts the concept of the celestial sphere, in which all heavenly bodies are apparently located on the interior surface of an infinitely large sphere that has the earth as its centre. The celestial sphere appears to rotate westward about the extension of the earth's axis of rotation.

The geographical position of a heavenly body is the point immediately below it on the earth's surface. The latitude of this position is defined by the body's declination and the longitude by its Greenwich hour angle. Both these values may be extracted from the nautical (or air) almanac for a particular time. In navigation the earth and the celestial sphere are considered as two concentric spheres and, since the radius of the earth is known, any angle measured in the celestial sphere can be directly related to distance on the earth's surface. A nautical mile by definition is the length on the earth's surface of one minute of arc.

A navigator making a timed sextant observation of the altitude of a heavenly body thus (subtracting it from 90°) measures the distance of his own position from the geographical position of the body. He establishes the body's geographical position for the time of the observation by reference to his almanac. The distance from this position can be laid off on the chart, in principle, as a circular position line, but in practice the distances are likely to be so large that this is not feasible. The astronomical triangle formed by the pole, the body and the observer's zenith is then solved mathematically.

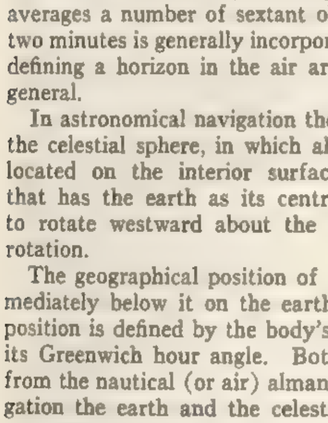


FIG. 2.—METHOD OF PLOTTING DEAD-RECKONING POSITION

Most modern solutions are based on the intercept method, in which the altitude and azimuth for any convenient position, such as a dead-reckoning position, are calculated for the instant of observation and compared with the altitude and azimuth obtained from the observations. The procedure is illustrated in fig. 2. Only the portion encircled by the dotted line need be plotted on the chart. The two circles normally differ only by a few minutes of arc, which results in the encircled position being relatively small. The line tangential to the circle of equal altitude for the actual position is perpendicular to the radius of the circle at the point of tangency. No appreciable error is involved, because a straight position line may be said to correspond over a comparatively short distance to a position circle of very large radius tangential to it. An astronomical fix is obtained by the intersection of two or more astronomical position lines.

III. TECHNIQUES AND INSTRUMENTS FOR MARINE NAVIGATION

In coastal navigation the ship's position is normally established by bearings of nearby landmarks. Lighthouses are placed in prominent positions around the coast and show lights by night with characteristic phases by which they may be identified. By day lighthouses are easily recognized landmarks, and their known heights are often used to obtain the distance by sextant angle. Light vessels are generally placed offshore either to mark some danger (such as the Goodwin Sands in the English channel) or as an aid to landfall (the Ambrose lightship off New York harbour). Lighthouses and light vessels are equipped with sound fog signals and usually with radio beacons.

Buoys are used to mark channels and off-lying dangers. The colour and shape of a buoy, and sometimes its numbering, indicate on which side it should be passed. Two systems of buoyage are in use internationally: the lateral and the cardinal systems. The cardinal system is used along coasts fringed with isolated dangers and reefs, and the marks vary according to the quadrant of true compass in which they are situated with reference to the danger. Buoys may be identified at night by their light characteristics, which are indicated on the chart.

Sailing directions or pilot books, published by national hydrographic authorities, give detailed descriptions of the coast line, landmarks, tides and currents, lights, dangers, etc., for every navigable part of a coast. They give detailed directions for entering harbours and describe the anchorages, port facilities, buoyage, etc. Light lists describe the characteristics of lights (with the exception of buoys) around the coast and the buildings that exhibit them. In strongly tidal waters, such as the English channel, a tidal stream atlas is published to show the strength and direction of the stream for every hour.

Charts are normally issued by the national hydrographic authority, which is generally a department of the navy. The hydrographic department of the British admiralty has world coverage with some 3,500 charts. The United States Hydrographic office also has world coverage. Since 1920, the International Hydrographic bureau at Monaco, of which most maritime nations are members, has standardized chart making and acted as a medium for the exchange of hydrographic information. Most sea charts are on the Mercator projection, the great advantage of which for navigation is that rhumb lines appear as straight lines. Information to keep charts up to date is published by the hydrographic offices in the form of "notices to mariners."

The directional reference most used by modern navigators is the gyrocompass. The magnetic compass is always installed as a standby, and it may be the only compass in smaller ships. The advantage of the gyrocompass is that it indicates true instead of magnetic north and is subject to fewer errors. The compass is used both for steering and for fixing the ship's position by bearings. (*See* GYROCOMPASS.)

The ship's log, which may be of the towed or submerged type, records the speed or distance steamed. The ship's speed may also be estimated from the speed of its engines.

Although the lead line, possibly the oldest navigating instrument, is still in use, sounding at any depth is normally done with the echo sounder, which gives a continuous indication of the depth of water. In well-surveyed areas the ship's position may be ascertained by comparing a continuous echo-sounding record of the bottom with the soundings shown on the chart.

IV. TECHNIQUES AND INSTRUMENTS FOR AIR NAVIGATION

The speeds involved in air transport call for quick navigational methods, even at the expense of some accuracy. It is largely for this reason that radio aids play such an important part in air navigation. It is also for this reason that the major decisions tend to

be taken on the ground in the planning stage, so that the function of cruise control and flight control in the air is to implement these decisions.

The route and the cruising altitude are selected on the basis of the predicted weather situation and various other factors. The choice of altitude will take into account the best operating altitude of the aircraft, the winds at different heights, icing, turbulence and the demands of traffic control. The route will be chosen bearing in mind winds and the weather situation, navigational facilities and traffic control. Although the shortest distance always lies along a great circle, the great-circle route is not necessarily the least-time track because the incidence of head and tail winds will depend on the local weather pattern. There are various techniques for calculating and flying along the minimal flight path, and these are grouped together under the heading of pressure-pattern flying.

When the route and altitude have been chosen, the flight plan, which is filed at the airport of departure for transmission to the airport of arrival, is drawn up. Wind triangles for various parts of the flight are solved; the heading, true air and ground speeds for each zone of the flight are determined; and the flight time and amount of fuel needed are calculated. An alternate airport is selected in case weather makes landing at the scheduled airport unduly hazardous, and a point of no return, or equitime point, is established. The flight plan is used as a guide against which the aircraft's progress in the air is constantly checked.

In contact flight the pilot uses prominent landmarks, such as highways, bridges, railroads, mountains and lakes, to establish his position. By night he uses air beacons, generally located at airfields and at intervals along more difficult portions of the civil airways. Another useful visual aid in contact flight is the runway-approach lighting, which extends for several hundred feet from the end of the runway to help the pilot make visible contact with the ground. The intensity of these approach lights can be varied from the control tower, and different settings are used for night and day use and for different types of overcast.

The scale and the amount of information displayed on an air navigation chart will depend on its purpose. A plotting chart may be on a scale of 1:2,000,000 and, in addition to such radio facilities as radio ranges, fan markers and beacons, such a chart will show airports, ground elevation, airways and control zones. It would show little topographical detail and would be used for high-speed high-altitude flight. Such charts are generally drawn on the Mercator or Lambert conformal projection (*see* MAP). The World Aeronautical series of charts, which has been recommended for international adoption by the International Civil Aviation organization, is on a scale of 1:1,000,000 and displays enough topographical and radio information for fairly high-speed pilotage. Instrument-approach-and-landing charts are designed to enable the pilot to approach and land by instruments in low visibility. The landing chart shows, on a larger scale, the airport and its immediate vicinity and is used for visual as well as instrument flying. Such a chart might be drawn on a scale of 1:250,000.

The gyroscope, although not used as a north-seeking compass in aircraft, plays a considerable part in the definition of heading in the air. Gyrostabilization is used to eliminate the acceleration errors to which magnetic compasses are subject in aircraft and to avoid interference from ferrous metals and electrical circuits in the region of the compass. The magnetic element in the remote-indicating air compass is normally housed in a position away from magnetic interference, such as the tail or outer part of the wing. The directional gyroscope is also used in place of a compass in instrument flying and in polar regions where the magnetic compass is useless. The gyroscope is subject to wandering due to precession and slowly drifts away from the original setting. During turns the drift is too small to be of any significance, but when used for steering the gyrocompass requires occasional resetting. In polar navigation the average drift rate, normally determined by the astrocompass, is generally allowed for in the courses steered.

To determine the effect of the wind on the aircraft's track, a drift meter may be used when the ground can be seen. In a typical instrument the navigator looks through an eyepiece and rotates an indicator dial until the drift lines on the reticle are parallel to the apparent motion of ground objects; a pointer on the indicating dial will then show the amount of drift. Modern drift meters are usually gyrostabilized. The gyroscopic principle is also incorporated in automatic sensing controls to achieve controlled flight.

Altitude is measured either with the barometric altimeter, which is essentially an aneroid barometer calibrated in feet or metres above sea level, or by an absolute altimeter, which employs a radar principle to measure the distance above the ground.

(H. A. PA.; M. W. RI.)

V. ELECTRONIC AIDS COMMON TO MARINE AND AIR NAVIGATION

Following the beginning of World War II, when the direction finder and its associated radio beacon and the low-frequency radio range station were the standard aids, there were enormous advances in radio aids to navigation. Systems developed during and after the war include loran, decca, consol, very high-frequency omnidirectional range (VOR or "omni"), distance-measuring equipment (DME) and radar.

Direction Finding (DF) and Omnidirectional Beacons.—The directional property of a radio antenna that is formed into a coil or loop was familiar to the earliest experimenters. As a loop is rotated horizontally its energy output, derived from the interception of a radio wave, passes through a sharp minimum that corresponds to the direction of the radio transmitter. Soon after ships were first equipped with radio, shore direction-finding (DF) stations were placed at strategic points along navigational routes and near harbour approaches. Upon receiving a request by radio from a ship, two or more shore stations determined the directions from which the ship's signal arrived by means of their loop antennas and transmitted this information back to the vessel. However, this service was limited to one vessel at a time, a serious drawback in bad weather, when demands were heavy. By reversing the process—placing the transmitter ashore and the direction finder on the ship—the system became nonsaturable and the navigator was given two further advantages: he was able to take continuous or frequent bearings on any shore beacon, and he could take bearings of any receivable signal, such as transmissions from broadcasting stations and from other vessels. This change in the system was roughly coincident with the initial growth of aviation, and the air-borne direction finder immediately became a valuable aid to air navigation.

Crossed-loop direction finders, used when it is not convenient to rotate the loop, consist of two loops mounted at right angles to each other with their terminals connected by cable to two crossed fixed coils of a goniometer; a rotatable coil in the goniometer simulates the rotation of the ordinary loop antenna. Other types of DF antennas include the Adcock (using spaced dipoles or monopoles) and spaced-loop types that have been employed ashore as navigational aids in the high-frequency and very high-frequency bands, where greater efficiency and accuracy is obtained than with the simple loop. Loops incorporating ferromagnetic cores are largely used in portable direction finders, produced principally for aircraft and small boats.

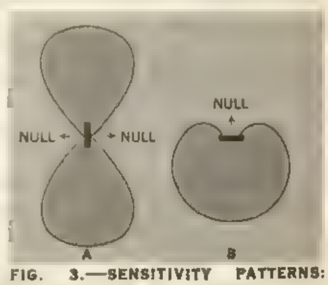

FIG. 3.—SENSITIVITY PATTERNS: (A) SIMPLE LOOP ANTENNA; (B) LOOP COMBINED WITH SINGLE VERTICAL ELEMENT

In all direction finders there exists a basic ambiguity of 180° as to the direction of signal arrival. This is resolved by combining the output of an omnidirectional "sense" antenna, usually a single vertical element, with the output of the DF elements so that the normal symmetrical figure-of-eight sensitivity pattern (fig. 3[A]) is altered to a cardioid pattern (fig. 3[B]) to show the direction of signal arrival.

Errors in Direction Finders.—The accuracy of well-designed direction finders is normally within 1° to 2°. Greater and sometimes serious errors are caused by night effect, reflection and shore-

refraction effects and local reradiation.

The term "night effect" originated when practically all direction-finding activity was in the 200–500 kc. band, utilizing the vertically polarized ground wave, which is uncontaminated in daytime. At night, however, the sky wave appears, arriving at the DF antenna at a down-coming angle and shifted both in phase and polarization, thus distorting the normal directional response of the antenna. At higher frequencies this effect exists even in daytime. The Adcock and spaced-loop antennas provide greater accuracy on sky waves than does the loop antenna.

Radio waves are refracted when crossing a boundary between dissimilar paths, such as a shore line, at angles less than 90°; likewise, mountains and similar masses may reflect the waves. Both of these effects cause the apparent direction of signal arrival to be other than the true direction of the transmitting station.

Metallic objects on the vessel, aircraft or at a land-based DF station may reradiate or reflect the incoming signal, thus causing the apparent bearing to be in error. On vessels, the offending objects are usually masts, rigging, metal guard rails and other antennas; on aircraft, other antennas and parts of the aircraft itself. Generally these errors are determined by observation and then either accounted for arithmetically or automatically corrected by special devices.

Automatic Direction Finders.—The direction finders installed on ships and aircraft are usually automatic adaptations of the manual single-loop or crossed-loop goniometer. Although the circuity used is fairly complex, the objective in most types is simply to maintain the loop or goniometer in a null position. This is accomplished by an electrical sensing circuit, which causes a motor to return the loop to zero voltage output whenever turning of the vessel causes the loop to depart from that position. The accuracy of such equipment is adversely affected by strong unwanted signals, and aural monitoring is necessary in order to detect such a condition. Instantaneous-bearing types of automatic direction finders are able to display several bearings simultaneously, in radial fashion, upon an oscilloscope. This is accomplished by rotating either a loop or goniometer synchronously with the deflection coil of the oscilloscope at a relatively high speed.

Radio-Beacon Stations.—The complementary part of a direction-finder navigational aid is a system of omnidirectional transmitting stations strategically located along navigational routes or on the approaches to harbours and airports. These beacons operate within the band 200–515 kc. The service distance is established by regulating the radiated power in accordance with area or local requirements, which range from 10 to 400 mi. Each station transmits its identifying code either by keying the carrier or by a tone modulation; the latter method is favoured because automatic direction finders operate more reliably on a continuous carrier. Because of limited radio spectrum space it is necessary in some areas for marine beacons to share time on the same frequency. The usual arrangement is for three stations to transmit one minute each, in close sequence, for two 10-minute periods in each hour. In poor visibility, however, a station is sometimes placed in continuous operation.

Loran (Long Range Navigation).—The loran system was developed in the United States during World War II to overcome the limitation in accuracy and distance of direction-finding and range systems. By changing from a continuous-wave (CW) bearing or directional array system to a pulse time-measuring system the night effect is eliminated and refractive and reflectional effects are minimized. In addition, because of the low ratio of "on" to "off" time in a pulse system, a very high peak power can be generated economically. The loran-A system covers most of the important trade routes of the world and is used by both marine and air navigators. It operates in the 1,800–2,000 kc. band. Loran-B, a refined version of loran-A designed for extremely high accuracy at lesser distances, is intended primarily for approach and in-harbour navigation. Loran-C, operating on 100 kc., provides greater range and greater accuracy than loran-A.

Loran pulse signals are short enough so that it is possible to discriminate between the highly stable ground wave and the unstable sky wave. The sky wave is delayed with respect to the ground wave at any reception point because of the greater distance it must travel—up to the ionosphere and back to earth. Although the primary service of loran-A is based upon the use of ground waves with a range of 600 to 900 nautical miles, secondary service is provided by first-reflection sky waves up to 1,400 mi. The fix accuracy within the primary area is nominally 1% of the distance from the centre of the station system; within the secondary area it is 5%.

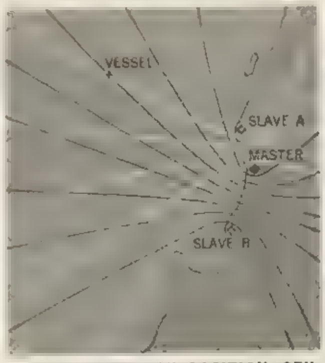

FIG. 4.—LINES OF POSITION GENERATED BY LORAN MASTER AND SLAVE STATIONS

Fig. 4 illustrates the loran system. Each pair of stations—master and slave A and master and slave B—transmits signals that generate a family of hyperbolas representing lines of equal difference in time required for a signal to arrive at a given point from each station in the pair. For example, the master station transmits a pulse signal; slave A—which may be 200–600 mi. distant—receives it, waits a predetermined interval and transmits a pulse. The pulses are about 50 μ sec. in length and are transmitted at a rate of about 20 to 34 per second. The base lines are shorter in loran-B and longer in loran-C. The loran-C pulse is much longer, and special techniques are employed to use only the early or ground-wave portion, the pulse rates are 10 to 34 per second. Since the velocity of radio waves in the atmosphere is known, it is possible to convert the difference in time of arrival of the pulses at a vessel to a difference in distance from the vessel to the loran stations.

With a conventional loran receiver, the navigator measures the time difference by observing the signals on an oscilloscope, although special equipment was developed to make the position-finding process completely automatic. On a loran chart, the hyperbolic lines of position usually are labeled in microseconds of time difference; they are spaced at convenient numerical intervals, and positions lying between lines are determined by interpolation.

Decca.—The decca system was developed in Great Britain during World War II and came into extensive use in Europe, India and Canada. Decca operates on various frequencies between 70 and 130 kc.

Like loran, decca is a hyperbolic system. Unlike loran, the signals are not pulsed. The distance difference of a point from two decca stations is measured in wave lengths and portions of a wave length or cycle phase, and the charted hyperbolic lines of position are based upon these units. Since a wave length at decca frequencies is many times smaller than the distance between the stations, there are many repetitions of the same cycle phase differences within the service area and these repetitions must be resolved for the navigator.

The master of a pair of decca stations transmits on a precise frequency, omnidirectionally. The slave station, typically located about 70 mi. distant, receives this signal and locks its own transmission in phase with it. Thus, in the service area there exist two signals whose effective relative phase is constant along hyperbolic lines of position. Since it is impossible to separate two signals that are on the same frequency at the input of a receiver at the same time, it is necessary for the stations to transmit on different frequencies. These are chosen so that with different small multiplying factors they may be converted, after reception through separate receiver channels, to the same frequency, called the comparison frequency. The two versions of the same comparison frequency derived from the master and slave stations are then applied separately to the inputs of a phasemeter. A decca system that contains as many as three slaves phase-locked to a single master would therefore employ four different frequencies with associated multipliers in the receiver to derive three different common-multiple comparison frequencies, each in pairs to actuate three line-of-position phasemeters or decometers. The decca phasemeter is of the counting type; that is, the normal limit

of 360° is extended many times by a geared counter. Thus, travel from any known point can be followed.

The relation between the action of the phasemeter and the movement of the vessel is understood by realizing that as movement takes place on the base line the change in distance with respect to the two stations is differential; therefore a movement of one-half wave length, or 180°, produces a 360° travel of the phasemeter. One of the several comparison frequencies, for example, may have a wave length of 3,000 ft. Since 280 half wave lengths may be contained in a base line 70 mi. long, serious ambiguities in position would result if the counting feature failed because of station or receiver trouble or if the receiver were turned on when at an unknown position. The ambiguity is resolved by temporarily shifting away from the pattern of fine half wave length lanes to coarse and intermediate lanes called zones and fine zones. This is accomplished by automatically shifting station frequencies and frequency-mixing circuits in the receiver for an instant each third minute in order to generate much lower comparison frequencies. The coarse zones are large enough to yield approximate positioning by means of ordinary navigational information, while the fine zones are small enough for identification of the fine lane.

Within the service area of a typical decca chain, line-of-position accuracies vary by day from 30 yd. at 100 mi. to 150 yd. at 250 mi. At night, sky wave contamination of the ground wave increases the error to 100 yd. and 800 yd., respectively, and the system becomes unreliable between 300 and 400 mi. Daytime accuracy is limited largely by small line-of-position crossing angles. However, these may be extended by using more than one chain of decca stations. Shore line and other refractional effects and obstacle reflections are inconsequential except when decca is employed in accurate surveys, when the relatively weak daytime sky waves must also be taken into account. A simple receiving antenna is adequate, and local reradiation is unimportant for ordinary navigation.

For hydrographic surveying a rearrangement of the conventional decca chain, in which the master station and receiver are situated in the survey ship with two stations on the coast, offers great advantages. In this system, known as two-range decca, the readings are a function of the distance from the ship to the stations ashore.

Consol.—Consol originated during World War II in Germany under the name of sonne. The system was further developed and transmitters installed with minor variations in Britain, France and the United States (under the name consolan). Consol is a long-range system employing various frequencies between 250 and 350 kc. No special receiver is required, except that a loop directional antenna is sometimes used to resolve certain ambiguities.

The consol system consists of a single station employing a directional antenna array that generates a multilobed horizontal radiation pattern. Over a period of one minute (or one-half minute in some applications) all lobes are rotated so that each eventually occupies the place formerly occupied by its neighbour in the direction of rotation. As the lobes are rotated they are keyed: one lobe transmits dots and its neighbour transmits dashes. The dots and dashes are alternate and contiguous. An observer located in the area of a dot lobe will hear only dots until the dot lobe moves away and the adjacent dash lobe approaches, the space between the dots of decreasing amplitude being filled in by dashes of increasing amplitude. When the dots and dashes become equal in amplitude the observer hears a continuous tone. The process of rotating the pattern is repeated after a short distinguishing interval. The navigator merely has to count dots or dashes in order to determine his line of position at the beginning of a sequence with respect to equisignal lines, or narrow zones, which are shown on a consol chart. The sum of dots and dashes for a single shift or sequence is 60, and accuracy can be improved by counting both characters and symmetrically adjusting them, if necessary, to the sum of 60. When the start of a count is on an equisignal line the count is all dots or all dashes. Semiautomatic counting devices are available.

Since there are a number of lobes and corresponding equisignal lines in the system, and the lobes enclose sectors of 10° to 15°, the navigator at times may need positive identification of the sector in which he is situated. This is accomplished by taking radio bearings on the consol station.

The range of consol is limited by spreading of the equisignal lines and by atmospheric noise that varies with latitude and season. Since sky waves are useful (more so than in direction finding) the range is greater at night. The nominal range is 1,500 mi. at night and 1,000 mi. during the day, with line-of-position accuracies ranging from 1.5 mi. at 250 mi. to 72 mi. at 1,500 mi. The accuracy is less at night over ranges of 200–400 mi. because of mutual interference between sky waves and ground waves.

Radar.—The development and application of radar progressed after World War II to make it probably the most widely used of all electronic navigational aids. Essentially, navigational radar extends the user's range of vision in darkness or poor visibility. The radar picture, however, is a symbolic one, unlike that of television, and proper interpretation requires considerable skill (*see* RADAR).

VI. ELECTRONIC AIDS FOR MARINE USE

Variations of Radar.—*Port radar* installations have been introduced in certain harbours to help traffic in poor visibility and for various subsidiary functions, such as checking the position of navigational buoys. In periods of bad visibility, pilots aboard the ships are advised of their positions in relation to the navigational marks or to the harbour configuration. However, when traffic is heavy there is sometimes difficulty in identifying a particular ship on the harbour radar display. This may be overcome in numerous ways, one of which is to take bearings on the ship's radio transmitter.

Two systems that operate on radar principles but that employ active rather than passive targets are shoran and EPI (electronic position indicator). Transponder (slave) beacons, established ashore, return strong signals of identifiable characteristics that facilitate accurate measurement of distance. Shoran, operating in the 210–320 mc. band, is a line-of-sight system. EPI is effective over a greater range, by virtue of ground waves, on about 2 mc. EPI actually is a mobile loran system that is limited to the measurement of the length of the base line between the interrogator (master) and transponder (slave) beacons. Both systems are primarily survey tools.

Sonar is the underwater counterpart of radar; however, it employs sound waves rather than radio waves. The terms echo sounder, Fathometer and depth finder are commonly applied to equipment that is designed to measure distance downward only. The employment of horizontally directed beams is generally restricted to military applications. (*See* also ECHO SOUNDER.)

Radux and Omega.—Radux, a hyperbolic system that operated experimentally in the low- and very low-frequency bands, employed base lines of approximately 2,000 mi. Advantage was taken of the relatively high stability of sky wave propagation at these frequencies to synchronize transmitters and receivers. Phase comparison and synchronization were made on a modulation frequency of about 200 cycles. Since radux was a continuous-wave system using a single radio frequency, transmission time had to be shared among the three or more stations in a single system. This was accomplished by a synchronized system of commutation in each transmitter and receiver. Phase "memory" of the transmission that had ceased was provided by a phase-controlled crystal oscillator.

Omega evolved from the experiments with radux. Phase measurement was shifted from the 200-cycle modulation of radux on a carrier frequency of 40 kc. to direct phase comparisons of 12-kc. master and slave station carriers. The lane width along the base line is thus reduced from 400 mi. to 7 mi., with an accompanying increase in line-of-position accuracies. For lane resolution a second frequency, offset from the main frequency, is transmitted alternately to give a low-frequency beat, the lane width of which is considerably greater. Together with the improved accuracy achieved by this change there were gained the advantages of greater transmission range and superior propagation stability.

Lorac and Raydist.—Lorac and raydist are short-range, continuous-wave hyperbolic systems developed primarily for accurate

surveying operations. Synchronization of the three or more stations is made unnecessary by using a single beat frequency generated between offset radio frequencies of the system. Both lorac and raydist operate principally on frequencies near 2 mc.

In lorac, phase measurements are made between two separate derivations of a beat frequency that is generated in the mobile receiver and also at one of the fixed stations of a pair and retransmitted to the mobile unit as a modulation of a third radio frequency. A fixing system is comprised of three or more stations. The number of frequencies required is reduced by time-sharing.

The raydist system is similar to loran, except that one of the transmitters is placed on the mobile station. Thus, raydist can be used as a pure distance-determining device. Neither system provides lane identification; therefore, lane count from a known position must be maintained. Accuracy is limited at night by sky wave contamination of the ground wave.

VII. ELECTRONIC AIDS TO AIR NAVIGATION

Four-Course Low-Frequency Radio Range.—The four-course low-frequency radio range system was the first electronic aid to navigation to come into general use after the development of the direction finder. It is basically a homing system, although a positional fix may be obtained by finding the intersection of the course lines of two stations. The range supplies a course on which is heard a continuous tone. As the aviator strays from the course he hears either the International Morse code character A (·—) or N (—·). By referring to a special chart, he is able to determine the direction in which he has strayed.

The transmitting antenna is a crossed loop or crossed Adcock whose four-lobed radiation pattern can be shifted by adjusting the relative amplitude and phase of the two directional elements. Along the desired course the amplitudes are made equal and since the A and N characters are interleaved, a continuous tone is heard. Elsewhere the signal amplitudes are not equal, so one character or the other predominates.

No special receiver is required for the range information. Reliable service distance is limited at night because of night effect, reflections from mountains and interference from other stations as well as from the reduction in power made to reduce that interference.

Omnidirectional Radio Range.—While the four-course range simplifies travel over established routes, the omnidirectional range serves general navigation and position-finding requirements. Historically the omnidirectional beacon had its beginning in the "talking beacon," which saw experimental service in the low-frequency band in Europe. In this device a recorded voice announced the direction of transmission of a beam, in steps of several degrees, as the beam was rotated 360°. The difficulty of generating, at low radio frequencies, the sharp rotating beam required for aural discrimination of the spoken information, together with night and refractional effects, limited the success of this system. The phase-comparison omnidirectional range, developed by the U.S. Civil Aeronautics administration on both low-frequency and very high-frequency bands, is highly sensitive to amplitude changes. It employs a rotating cardioid pattern that is compared with a fixed-phase, omnidirectional pattern, the carrier of which is modulated at the speed of rotation of the cardioid. If the relative phase of the two patterns is established at 0° when the maximum amplitude of the cardioid is pointed north, then successive positions of the cardioid will produce a direct indication of bearing from the transmitting station on a receiver phasemeter.

The very high-frequency (108–118 mc.) omnidirectional range (VOR) has been widely installed in the U.S. and, to a lesser extent, in other countries. It is sometimes combined with an interrogator-transponder beacon (DME, or distance-measuring equipment), which is similar in principle to shoran.

Dectra.—Dectra is an adaptation of the nominally short-range decca system to long-range lane guidance. A master and a slave, sharing the same frequency, are situated 70 to 80 mi. apart so that asymptotic hyperbolic lines extend along a desired traffic route. A second pair is similarly set up at the opposite end of the route and shares a second frequency. The route distance and station power are adjusted so that each pair covers somewhat more than half of the route. Distance information is provided by utilizing the signals so as to establish a base line between the two pairs of stations. When signals from either end of the route cannot be received, a highly stable crystal oscillator provides a temporary "memory" signal. A transatlantic dectra installation provides accuracies of 3 mi. laterally and 6.5 mi. along the route, the lateral accuracy improving radically as the stations are approached.

Variations of Radar.—In aircraft radar equipment of special design, use is made of the Doppler effect, which causes the received frequency of a signal reflected from the ground to differ from that of the transmitted signal by an amount proportional to the speed of the aircraft. Several downward beams having horizontal components in different directions may be utilized so that the forward lateral and vertical velocity of the aircraft may be measured by automatic means. Doppler systems have been developed using either pulse or continuous-wave methods.

The radio altimeter, which utilizes radar principles, has an advantage over barometric altimeters in that it is independent of variations in sea-level air pressure. This property enables the air navigator to relate his progress to the position of high- and low-pressure meteorological centres by noting the changes in the relative readings of his barometric and radio altimeters. Since wind direction bears a fixed relationship to pressure centres, these pressure-pattern data are useful in selecting a route. (F. B. D.)

VIII. INERTIAL GUIDANCE SYSTEMS

Inertial guidance systems are self-contained, dead-reckoning devices that are most valuable for submarine navigation and missile control, although their usefulness is not limited to these applications.

The basic data upon which the inertial system depends are the amount and direction of acceleration. If acceleration from a standstill occurs for only a short period of time, after which velocity becomes constant, then velocity becomes the product of elapsed time and acceleration per unit distance per unit time. However, velocity is seldom constant. The variations in acceleration, both positive and negative, throughout the duration of motion must be integrated. The variation in acceleration is continuously determined by measuring the inertia presented by a mass to a change of velocity. This integrated information, which is proportional to velocity, is then interpreted in a second operation to yield data that are proportional to the distance traveled. All acceleration measurements and integration operations are performed automatically. It is obvious that when very small changes in velocity are involved the detection and measurement of acceleration is an extremely delicate operation and requires that the reference mass be isolated from varying local effects. Reference axes, which are fixed with respect to free space, are established by three spinning gyroscopes mounted on gimbals whose axes are mutually perpendicular. Deviations from this reference frame are sensed and fed to a computer, where the information is consolidated and resolved into distance and direction of travel.

In guided missiles the direction and distance of travel are preselected and thereafter automatically controlled. The effects of the earth's centre of gravity, whose direction with respect to the free space reference varies with changes in geographical position and with the earth's rotation, present problems of considerable magnitude since they introduce a component into the indicated measurement of acceleration and direction. As in any dead-reckoning method, errors are accumulative with time.

IX. INTERPLANETARY NAVIGATION

The three stages of an interplanetary flight by a high-thrust rocket may be considered to be (1) the launch, when the vehicle accelerates rapidly away from the starting point; (2) the mid-course phase, when the vehicle is in free fall, subject only to the gravitational fields of the sun and planets; and (3) the approach and landing phase. The first and last phases can be controlled by radio and radar, since the distances involved are relatively small. The mid-course phase comprises the major part of

the voyage, however, and presents serious navigational difficulties. During this phase the rocket will be traveling in an orbit, the shape of which is determined precisely by the speed and direction of its motion, that is, by its initial velocity on launching. The sort of difficulty involved in determining position and velocity in space is illustrated by the fact that the distances and positions of the planets themselves are not known to accuracies of more than 1,000 mi. Measures of velocity based on such data, therefore, will clearly be even less accurate.

NAVIGATION LAWS. Historically this expression refers to laws passed at various times and places to restrict commerce to ships of a particular nationality. But the expression is also used less strictly to denote laws that lay down rules of the road and in other ways regulate the actual navigation of ships; this usage is covered in RULES OF THE ROAD AT SEA.

In England the first navigation act was passed in 1381. Policy varied thereafter until in 1651 a navigation act was passed in order to strike a blow at the maritime supremacy of the Netherlands. The system established, which required the national trade by sea to be carried in ships under the national flag, was maintained in force (with certain later statutory amendments) for a period of two centuries. By the navigation acts, ships under the national flag were required to be owned by British subjects, and shipmasters and a proportion of the seamen were also required to be British. Moreover, the national register for ships was established by Charles II in 1660 in order to ascertain which ships were to benefit from the acts. (*See* also MERCANTILE SYSTEM.)

The result of these acts was that by 1847 no produce from Asia, Africa or the United States could be imported into the United Kingdom from Europe in any ships, the object being that the trade should be direct and in British vessels. Coastal trading around the United Kingdom could be carried on only by British ships, and colonial trade was prohibited to all foreign ships except where sanctioned by a special order in council. Various restrictions were imposed on imports not carried in British ships, and orders in council laid down differential dues and restrictions on imports carried in ships of any foreign countries that imposed similar restrictions on British trade.

In 1849 the navigation acts were repealed, subject to reservation of the coasting trade and subject to the proviso, intended to secure reciprocity, that if prohibitions or restrictions were imposed on British ships by other countries the privileges of the ships of those countries in British ports might be restricted. The reservation as to coasting trade was removed in 1854.

However, despite these relaxations, it is still the law that a ship is not to be deemed a British ship unless it is owned wholly by British subjects, or by a body corporate established in some part of the sovereign's dominions. British ships are still required to be registered as such. Further, no alien can own, nor, subject to certain reservations, may he act as master or as one of the principal officers of a British ship. (Ds. B.; X.)

In the United States almost immediately after the adoption of the constitution in 1789, the first congress recognized the necessity of a merchant fleet in time of peace to carry the commerce of the new nation, as well as the necessity for shipyards from which could come ships of war in any national emergency. Thus, in 1792 it enacted a law that provided that, in order for a vessel to be registered as a vessel of the United States and to be entitled to the protection inuring to a vessel so registered, it must be built in the United States, wholly by U.S. citizens, and must be commanded by a master who was a citizen of the United States, native-born or naturalized. In 1790 a tonnage tax that discriminated in favour of U.S. vessels was imposed.

Under various statutes, provision was made for relief by way of reciprocity, and, consequently, after 1849, British ships were admitted into U.S. ports on the same terms as U.S. ships were admitted into British trade.

In 1878 the U.S. congress codified all of the laws of the United States, under appropriate chapter headings, into a compilation entitled *Revised Statutes of the United States.* Virtually all of the then existing laws of the United States affecting maritime commerce, the inspection of vessels, the licensing of merchant marine officers and the protection of merchant seamen were placed in ch. l to liii.

It appears that in 1886 congress became aware of the inroads that were being made by foreign vessels into the transportation of passengers between ports in the United States. As a result, a statutory prohibition to the carriage of passengers by a foreign vessel between ports in the United States was enacted.

Similarly, in 1920 congress made it unlawful for a foreign nation to carry merchandise between ports and places in the United States in a vessel that was not built in, and registered in, the United States and owned by U.S. citizens.

During the early 1930s, it became apparent that the World War I merchant fleet of the United States, including passenger vessels, tankers and freighters, was becoming obsolete, and that the U.S. merchant marine was rapidly disappearing from the sea because of its inability to cope with lower construction and operation costs in foreign countries. To correct this situation and to have available a modern fleet of merchant ships for national emergency, congress enacted the Merchant Marine act of 1936. Under this act, the U.S. maritime commission is authorized to pay a construction subsidy to encourage citizens of the United States to have their vessels built in U.S. shipyards. The amount of this construction subsidy is usually the difference between the cost of building a vessel abroad and the cost of building a vessel in the United States. Each ship built under a construction-differential subsidy must, when completed, be registered as a vessel of the United States. To further encourage citizens to operate vessels under the U.S. flag, the maritime commission is also authorized to award operating differential subsidies. The amount of such payment is the difference between the cost of operating a U.S. vessel in the foreign trade and that of operating a similar vessel under foreign registry in the same trade. (F. K. A.)

After World War I, and in implementation of the terms of the peace treaty, conferences were convened under the auspices of the League of Nations with the object of facilitating and maintaining freedom of communications and of commerce. Several international conventions were adopted, the most important being the Maritime Ports convention, 1923. Under this convention each of the contracting parties undertook, subject to the principle of reciprocity, to grant the vessels of every other contracting state equality of treatment with its own vessels, or those of any other state whatsoever, in the maritime ports situated under its sovereignty or authority. The equal treatment was in regard to freedom of access to the port, the use of the port and the full enjoyment of the benefits as to navigation and commercial operations that it offered to vessels, their cargoes and passengers. This convention did not apply to maritime coastal trade.

After World War II, the Provisional United Maritime Consultative council, consisting of 18 members, including the United Kingdom, the dominions and the United States, was established at

Washington, D.C., in 1946 for the purpose, among other things, of removing all forms of discriminatory action.

In 1948 a conference was held at Geneva, Switz., at which the great majority of the members of the United Nations, with the notable exception of the U.S.S.R., were present. The conference adopted a convention for the constitution of an intergovernmental consultative organization, the aims of which were to follow the lines of those of the provisional consultative council. The Intergovernmental Maritime Consultative organization (IMCO) came into existence in 1958, with its headquarters in London, Eng. Its first formal meeting was held in Jan. 1959 in London. IMCO consists of an assembly, a council, a maritime safety committee and a secretariat. It is brought into relationship with the United Nations in accordance with art. 57 of the UN charter as the specialized agency in the field of shipping. The purposes of IMCO are to provide machinery for co-operation among governments in the field of governmental regulations and practices relating to technical matters affecting shipping engaged in international trade, to encourage the general adoption of the highest practicable standards in matters concerning maritime safety and efficiency of navigation, to encourage the removal of discriminatory and restrictive practices in international trade and to consider unfair restrictive practices by shipping concerns. Membership of IMCO consists of the governments of nearly all maritime nations and of some nonmaritime countries. *See* also WATERS, TERRITORIAL.

NAVSARI (NAOSARI), a municipality and *taluka* (administrative subdivision) of Surat district in Gujarat, India, formerly in the Navsari division of the princely state of Baroda. The town lies on the left bank of the Purna river, 147 mi. N. of Bombay by rail. Pop. (1961) 51,300 (town). It was one of the early settlements of Parsees in Gujarat, where they landed after their banishment from Persia (Iran). It is still the home of their mobeds, or second sacerdotal class, and contains their most venerated fire temples. The town also has mosques, Hindu pagodas and an old palace. (M. R. P.)

NAVY: *see* NAVAL AFFAIRS (ARTICLES ON).

NAWABGANJ, the name of three towns in India and one in Pakistan.

1. The most important lies 17 mi. N.E. of Lucknow, in Barabanki district, Fyzabad division of Uttar Pradesh, India. Pop. (1961) 27,080. It is contiguous with the district headquarter town of Barabanki (*q.v.*), with which it forms a municipality. The main market and educational institutions of the district are in Nawabganj. It is connected with Lucknow and Fyzabad by road.

2. A municipal town of Gonda district in the Fyzabad division of Uttar Pradesh. Pop. (1961) 6,249. It lies about 3 mi. from the north bank of the Gogra (Ghagra) river and 24 mi. S.S.E. of Gonda on the Fyzabad-Gonda road, and on a branch line of the North Eastern railway. The main occupation is trade in food grains. The town is named after Nawab Shuja ud-Daula, who built a market there.

3. A town of Bareilly district in the Rohilkhand division of Uttar Pradesh. Pop. (1961) 7,198. It lies 18 mi. N.E. of Bareilly on the Bareilly-Pilibhit road. It has an assembling market for food grains, and a large fair takes place there during the Dasahra (worship of the Ganges) festival. The town is named after Nawab Asaf ud-Daula.

4. A town in the Rajshahi district of East Pakistan on the Mahananda river, 25 mi. N.W. of Rajshahi. Pop. (1961) 29,725. It has rail and road connections and is a trade centre for rice, wheat, jute and silk. (B. SI.; X.)

NAXOS, a Greek island, largest of the Cyclades (about 22 mi. by 16 mi.), lies east of Paros, with which, and adjacent smaller islands, it forms an eparchy. Pop. (1961) 16,703. Rich in vines and famous for its wine, it was a centre of the worship of Dionysus. According to legend the god found Ariadne asleep on its shore, when she was deserted by Theseus. The island shared the Early Bronze Age culture of the Cyclades. Its white marble and emery were exploited for the earliest major sculpture of the 7th century B.C., and it is credited with a part in the early development of Ionic architecture. During the 6th century B.C. a tyrant Lygdamis ruled Naxos in alliance with Pisistratus of Athens. In 499 B.C. a Persian fleet attacked it unsuccessfully, but in 490 it was captured by the Persians and treated with severity. Four Naxian ships joined the expedition of Xerxes, but deserted to the Greek side at Salamis in 480. Naxos was a member of the Delian league (*q.v.*); but, after revolting in 471, it was captured by the Athenians and remained in their possession until 404. In 376 it saw the Athenian defeat of a Spartan fleet. After its capture, in A.D. 1207, by the Venetian Marco Sanudo, the duchy of Naxos flourished till the Turks took the island in 1566. After the War of Independence it belonged to Greece. Remains of a 6th-century temple are on an island (Palati) just northwest of the town of Naxos. Naxos Island is rich in fruit trees, and exports corn, wine and oil, but its most important product is emery. (J. Bo.; X.)

NAXOS, the earliest Greek colony in Sicily, was founded by Theocles from Chalcis *c.* 734 B.C., on the east coast, south of Tauromenium (modern Taormina), just north of the mouth of the Alcantara river on modern Capo Schisò. There were already Sicels at Tauromenium, but they cannot have offered any opposition. The adoption of the name of the Aegean island Naxos may show that there were Naxians among its founders. It soon founded Leontini and Catana (modern Catania). Naxos was the warmest ally of Athens in the Sicilian expedition (415–413). In 403 B.C. it was destroyed by the elder Dionysius of Syracuse and its territory given to the Sicels. Its exiles at last found refuge in 358 at Tauromenium.

Investigations from 1953 onward not only revealed the streets, buildings and walls of Hellenic Naxos but by means of stratigraphic excavation documented its history and disclosed several prehistoric (Siculan and still more primitive) periods of occupation.

See G. V. Gentili, "Naxos alla luce dei primi scavi," in *Bollettino d'Arte*, anno xli, serie iv, pp. 326–333 (1956).

NAYAR (NAIR), a Hindu caste of the Malabar coast in Kerala, southwest India. Before British conquest (1792), the region contained small, feudal kingdoms in each of which the royal and noble lineages, the militia, and most land-managers were drawn from the Nayars and related castes, who ranked below the Nambudiri Brahmans or religious authorities. During British rule Nayars tended to move into professions and became prominent in politics, government service, medicine, education, and law. Many were active in the Congress party, which won independence for India in 1947.

Unlike most Hindus, Nayars traditionally were matrilineal. Their family unit, whose members owned property jointly, included brothers and sisters, the latter's children, and their daughters' children. The oldest man was legal head of the group. Rules of marriage and residence varied somewhat between kingdoms. In central Kerala adults of the matrilineal group lived together and husbands merely visited their wives. In the extreme north and in southern Kerala, at least by the 18th century, men of the group tended to live together in the joint-family house along with their wives and immature children.

Between the 16th and 18th centuries, Nayars in the central kingdoms of Calicut, Walluvanad, Palghat, and Cochin had highly unusual marriage customs that have been much studied. Before puberty a girl ritually married a Nayar or a Nambudiri Brahman. The husband could visit her (but was not obliged to); in some cases ritual divorce immediately followed the ceremony. After puberty a woman could receive a number of visiting husbands of her own or higher caste. Nayar men might visit as many women of appropriate rank as they chose. Women were maintained by their matrilineal groups, and fathers had no rights in nor obligations to their children. Nayars of this area therefore did not institutionalize the nuclear family of father, mother, and children as a legal, residential, or economic unit. The Nayars, however, did not wholly lack concepts of marriage and paternity, for the ritual marriage was essential and, in at least some areas of central

Kerala, children were required to observe ceremonial mourning at the death of their mother's ritual husband.

Early in the British period Nayar armies were disbanded. Perhaps partly as a result, plural marital unions gradually died out in the 19th century. A law passed in 1896 permitted a man to register his marriage and provided that children of this union should inherit half of his personal property. The pre-puberty marriage became a mere initiation rite, and a girl customarily married one legal husband after puberty. Their children began to be maintained by the father, to support him in old age, and to perform the ceremonies at his death. Laws passed in the 1930s enforced monogamy, permitted division of the matrilineal estate among male and female members and gave children full rights of maintenance and inheritance from the father. By the 1960s it was increasingly common, especially in towns, for nuclear families to form separate residential and economic units.

Mencher, "The Nayars of South Malabar," in M. F. Nimkoff (ed.), *Comparative Family Systems* (1965). (E. K. G.)

NAYARIT, a Pacific state of Mexico, until 1917 the federal territory of Tepic, bounded by Sinaloa, Durango, and Jalisco. The offshore Tres Marías Islands are largely undeveloped. Area 10,664 sq.mi. Pop. (1960) 389,929. The Southern Pacific Railway to Mexico and the trunk highway from Nogales to Guadalajara cross Nayarit. Running southeasterly, the Sierra Madre Occidental rises steeply from the narrow Pacific littoral and cuts the state into deep gorges and narrow valleys. Outstanding features are the volcanoes Ceboruco and Sanguangüey. Its climate is generally wet, frost-free, and healthful. Nayarit's coastal lagoons and marshes are well known as wild bird refuges. The main river is the final leg of the Lerma, rising on the main plateau of Mexico; under the name of Santiago it flows westward through Nayarit and empties north of San Blas, chief Pacific port. Its valley is extremely fertile. Mining is important in the Sierras, but Nayarit is primarily agricultural; its products include maize, tobacco, sugar, cotton, beans, coffee, woods, and medicinal plants.

Tepic (pop. [1960] 54,069) is the capital, 26 mi. SE of San Blas, with which it is connected by road. It is located in a valley 3,000 ft. above sea level, and is surrounded by ranches and small farms. Tepic is a mixture of colonial charm and bustling modernity. Small villages of Cora and Huichol Indians are scattered through the Sierras. (J. A. Cw.)

NAYLER (NAYLOR), **JAMES** (1618–1660), one of the most prominent early Quakers, was born at Ardsley, Yorkshire, in 1618. He served in the Parliamentary Army (1642–51) and was for two years quartermaster under John Lambert. During this period he began preaching as an Independent until in 1651, after a meeting with George Fox (*q.v.*) at Wakefield, he became a Quaker. For three years he worked closely with Fox and underwent a 20-week imprisonment for blasphemy in 1653. In 1655 he went to London and achieved a prominent position among Quakers there, but came under the unfortunate influence of certain overenthusiastic Quaker women who persuaded him that he was a reincarnation of Christ. Nayler and his followers traveled through the west country on their way to visit Fox in prison at Launceston, but were imprisoned at Exeter. There Fox visited him and they parted in disagreement, since Fox was then striving to free Quakers from the lawlessness of the ranters. In October 1656 Nayler and his entourage entered Bristol in procession imitating Christ's entry to Jerusalem. For this he was arrested, tried before Parliament, and sentenced to severe punishment and imprisonment. In 1658 he acknowledged his error in a letter to Parliament and was released in 1659. He was reconciled with Fox in 1660 and preached again in London until his death in October 1660.

See E. Fogelklou, *James Nayler: the Rebel Saint* (1931).

NAZARENE, CHURCH OF THE, an international religious body with headquarters in Kansas City, Mo., with over 300,000 members, largely in the United States, Canada, and the British Isles, and over 50,000 members in approximately 35 mission areas. The denomination is the product of the merger of some 15 religious bodies stemming from the 19th-century Wesleyan Holiness Movement. The first major merger was in 1907, uniting the Church of the Nazarene (organized in California in 1895) with the Association of Pentecostal Churches of America (with origins in the northeastern states from 1886 to 1896) to form the Pentecostal Church of the Nazarene. The next year the Holiness Church of Christ (with origins in the southwestern states from 1894 to 1905) joined the denomination. Later mergers brought in groups from Texas, Tennessee, Scotland, North Dakota, and England. The term pentecostal, because of its increasing association with "speaking in tongues," a practice foreign to the Nazarenes, was dropped from the name of the denomination in 1919. In polity the church combines congregational autonomy with superintendency in a representational system. In worship there is emphasis on simplicity and revivalistic evangelism. In doctrine the church stands in the tradition of Arminian Methodism and regards its unique mission to be the promotion of entire sanctification as a work of grace subsequent to conversion. It is the largest of the bodies with this professed aim.

The church operates a publishing house, a theological seminary, six liberal arts colleges, several theological colleges, and numerous mission schools and hospitals.

See *Manual of the Church of the Nazarene* (published quadrennially); T. L. Smith, *Called Unto Holiness, the Story of the Nazarenes: the Formative Years* (1962). (C. O. B.)

NAZARENES, a translation of two different Greek words, *Nazarenos* and *Nazoraios*. The first means "coming from Nazareth" (a village in Galilee) and is applied to Jesus in the Gospels of Mark and Luke. The second, of doubtful derivation, may be related to the term Nazirite (*q.v.*) and is used of Jesus in Matthew, Luke (once), John, and Acts. Matthew (2:23) treats it as the equivalent of *Nazarenos;* in other passages its meaning is not altogether clear. According to Acts 24:5, it was used of Christians by Jews. In later times there was an Ebionite sect (*see* EBIONITES) which, according to the 4th-century theologian Epiphanius, consisted of Jews who traced their ancestry back to the Jewish Christians who left Jerusalem for Pella, on the other side of the Jordan, just before the destruction of Jerusalem in A.D. 70. Epiphanius differentiates this sect of Nazarenes from a purely Jewish sect which he calls that of the Nasaraei. The relation, if any, of these sects to the Jewish Christians of the 1st century cannot be determined. (R. McQ. G.)

NAZARETH (Hebrew NATSRAT; Arabic AN NASIRA), a town in Lower Galilee in Israel, on the northern border of the plain of Esdraelon. Pop. (1961) 25,047. A cigarette factory (with its own large tobacco plantations), stone quarries, and two mineral-water factories furnish employment for most of the inhabitants.

Nazareth is not mentioned in the Old Testament. In the New Testament (it is mentioned 28 times in the Gospels and Acts) it is associated with Jesus as his boyhood home, and in its synagogue he preached the sermon that led to his rejection by his fellow townsmen. Since the 6th century a number of churches and religious houses have been built there. Legends and precarious identifications persist, and visitors are shown the church of the Annunciation, the workshop of Joseph, St. Mary's well, Christ's table, etc. Only for the well can authenticity be assured.

The crusaders captured Nazareth in 1099 and transferred there the bishopric of Scythopolis (Beisan). It was taken by Saladin (1187) and retaken by Frederick II (1229). On its capture by the mameluke sultan Baybars (1263), the Christian inhabitants were massacred. In 1517 it came into the possession of the Turks. Headquarters of the Turkish-German Army during World War I, Nazareth was captured by the British in September 1918. In 1948 it was the headquarters of the Arab forces under Fawzi Kawukji until he was defeated by the Jews, when Nazareth surrendered without a fight. Under Israeli rule the town was placed under a military governor, his staff and government officials being the only Jewish residents there. (E. Ro.; X.)

NAZIM HIKMET RAN (1902–1963), Turkish poet and dramatist, who exercised a strong influence on Turkish literature in the late 1930s by his mastery of language and by the introduction of a wide range of poetic themes and of a free verse technique. He was educated at Istanbul and in Moscow. Having gained some

early recognition with his patriotic poems in syllabic metre, he came, in Moscow, under the influence of Russian futurists and, abandoning traditional poetic forms, he indulged in exaggerated imagery and by this means and the use of unexpected associations tried to "depoetize" poetry. Later his style became quieter and his epics on Bedreddin (the 15th-century revolutionary religious leader of Anatolia) and on the War of National Liberation show real poetic power. His plays, written in vigorous prose, are mainly Marxist inspired. His poems were translated into French by Hasan Gureh (1951). He died in Moscow on June 2, 1963.

See E. Saussey, *Prosateurs turcs contemporains* (1935). (F. I.)

NAZIRITE (NAZARITE), among the ancient Hebrews, a sacred person whose separation was most commonly marked by not cutting the hair and by abstinence from wine. In Israel's early history the Nazirite was endowed with special charismatic gifts and normally held his status for life; in later times he was a man who had voluntarily vowed to undertake special religious observances for a limited period of time, the completion of which was marked by the presentation of offerings (Num. vi; I Macc. iii, 49; Acts xxi, 24).

The early Nazirite was a holy man whose peculiar endowment, credited to his possession of "the Spirit of the Lord," was displayed in unusual psychic or physical qualities marked by spontaneity, ecstasy and dynamic enthusiasm. In this respect he had much in common with the early ecstatic prophets and with diviners such as Balaam (Num. xxii–xxiv), both indigenous to the near east. This helps to explain why Amos mentions the prophet and Nazirite together as persons whose special divine vocation had been frustrated (Amos ii, 11 ff.). Both were also close to the warrior, who was likewise in a sacred state while on duty. After his anointing Saul exhibited the ecstatic qualities of the prophets he joined (I Sam. x, 9–13; *cf.* xix, 18–24), and he exhibited a similar holy fury as the warrior king who led the relief of Jabesh-gilead (I Sam. xi, 5–11). Samson the Nazirite was a holy warrior whose special power was most closely related to his unshorn locks. This association of mysterious divine power with the growth of hair and with abstinence from wine shows that the institution of the Nazirite had its historic roots in the nature mysticism of the near east. In Israel, however, such natural powers as represented by the growth of hair were no longer treated as divine force, per se, but as signs of the power of the God of Israel and vehicles for it.

The later Nazirite as described in Num. vi and in the Mishna was not a charismatic person. He simply retained the old requirements, added the prohibition against touching a corpse, and treated them as external signs of a vow. The minimum period of the Nazirite vow was 30 days.

The priest-prophet Samuel, who was dedicated by his mother (I Sam. i, 11), did not exhibit the psychic phenomena of earlier Nazirites. In many respects he represents the bridge figure marking the transformation of the institution. The Rechabites (*q.v.*), who resembled Nazirites in abstaining from wine, also combined a voluntary vow with a lifelong commitment.

NAZZAM, AL- (ABU ISHAQ IBRAHIM IBN SAYYAR IBN HANI' IBN ISHAQ) (775–846), one of the great Muslim theologians and an accomplished man of letters, historian and jurist, was born in Basra (in modern Iraq) and brought up there before moving to Baghdad. He was the most illustrious student of Abu al Hudhayl al 'Allaf (d. 840), the great Mu'tazilite theologian of the Basra school. A man of phenomenal memory, he memorized the Koran, the Pentateuch, the Gospels and the Book of Psalms; it is told that when Ja'far, the vizier of the caliph Harun al-Rashid, questioned him on Aristotle's *Metaphysics*, he recited the work verbatim forward and backward. Together with his teacher, al-Nazzam led philosophic and theological thought in Islam in one of its formative periods. He fought Islam's battles against *Thanawiyyah* (Manichaeism) and *Dahriyyah* (materialism), and argued with Muslim sectarians like the *Jabriyyah* (determinists), *Mushabbihah* (anthropomorphists), etc. He stood for thoroughgoing rationalism in philosophy and theology, but he also defended the political claims of the Shi'ah sect. This gave rise to grave concern and some misunderstanding of his work.

His major contribution was his insight into the problem of human freedom. Man is incapable of his actions, he held, inasmuch as they are acts of his body (or, in modern parlance, belong to the material order where natural law is necessary and constitutive). But, he argued, this is not to concede the point to the *Dahriyyah*. For man is equally a *ruh* (spirit) which is not subject to this necessary determination but is free to resist or to acquiesce to it, thus incurring moral desert and punishment. None of his works has survived. Knowledge of him comes from his student al-Jahiz and from the Islamic heresiological writings. *See* also MU'TAZILITES.

NDEBELE, a people also known as Matabele, northern Zulu or Landeens. One section live in that part of Southern Rhodesia known as Matabeleland (pop. approx. 300,000 in the 1960s); they speak Sindebele, a click language of the Nguni (*q.v.*) group of southern Bantu languages. The Ndebele originated as the tribal following of one Mzilikazi of the Natal Nguni clan of Kumalo. A military commander of the Zulu king, Shaka, he was obliged in 1822 to flee from the wrath of his master and migrated with his followers first to Basutoland and then northward to the Marico valley. In 1837, after conflict with settlers of the Transvaal republic, he moved across the Limpopo river into the present Matabeleland (*see* TRANSVAAL). Here Lobengula, his successor, was able to extend the Matabele power until the establishment of the British South Africa company in 1890. There followed the Matabele war of 1893 in which Lobengula was defeated, and he died soon after. No successor was recognized and the Matabele were administered by the company as a number of separate districts (*see* BRITISH SOUTH AFRICA COMPANY).

The Matabele state incorporated the various peoples it conquered and the nation became stratified into a superior class (*Zansi*) composed of the true Matabele and other peoples of Nguni origin; an intermediate class (*Enhla*) that comprised people of Sotho origin; and an inferior class (*Lozwi* or *Holi*) derived from the original inhabitants of Matabeleland. A man was ranked by his class and then by his clan or tribe. Men of all classes were organized into age regiments that were fighting units and also localized territorial groups. The men of a regiment, on marriage, continued to live in their fortified regimental village, and its area formed an administrative district within one of the four provinces into which Matabeleland was divided.

The name Ndebele is also given by their Sotho neighbours to those Nguni tribes living west of the Transvaal Drakensberg (*see* DRAKENSBERG MOUNTAINS). They numbered about 144,000 in the 1960s and are sometimes called the Transvaal Ndebele to distinguish them from the Ndebele of Southern Rhodesia. *See* also RHODESIA AND NYASALAND, FEDERATION OF.

(G. I. J.)

NEAGH, LOUGH, in Northern Ireland, is the largest lake in the British Isles. Averaging 15 mi. wide and 19 mi. long, it covers 150 sq.mi. and has a catchment area of 2,200 sq.mi. Its chief feeders are the Upper Bann river, the Blackwater and the Main, and it is drained northward by the Lower Bann. The lake owes its origin to warping and faulting of the Tertiary basalt cover of northeast Ireland, and it is underlain by Lough Neagh clays which were deposited in a larger lake of probably Eocene age. Its average depth is less than 40 ft. and the shores are shelving and frequently boggy. Five of the six counties of Northern Ireland share the lake shores. Post-glacial fluctuations of lake level are evidenced in submerged forest peats which are of great archaeological interest because from them the oldest recorded artifacts of man in Ireland have been recovered, in Toome bay. Giraldus Cambrensis, in his *Topographia Hibernica* (*c.* 1188), records a

tradition that the lake came into being miraculously, "overwhelming the whole people and their flocks" as a punishment for their vices, and states that fishermen had seen the round towers of churches under the water. The legend is also recalled in the ballad "Let Erin Remember," one of Thomas Moore's *Irish Melodies*. Ram's Island, in County Antrim, has a ruined round tower; there are archaeological remains also on Coney Island in County Armagh, a National trust property, which is locally believed to have given Coney Island, N.Y. its name. Lough Neagh hones, once famous, were believed to be evidence of the petrifying powers of its waters, but the silicified wood from which they were made is derived from the Lough Neagh clays. The lake is celebrated for its eels and also has salmon and pollan, a freshwater member of the herring family. Flood control works have been undertaken from time to time, those in 1959 involving a lowering of the lake level to 50 ft. above sea level. The ministry of finance, Northern Ireland, is the drainage authority. (E. E. E.)

NEAGLE, JOHN (1796–1865), U.S. portrait painter, was born in Boston on Nov. 4, 1796, and spent his professional career in Philadelphia, where he died on Sept. 17, 1865. Starting as an apprentice coach painter, Neagle became a competent technician, but well below Gilbert Stuart and Thomas Sully; most of his large output is monotonous. His famous "Pat Lyon at the Forge" (Pennsylvania Academy of the Fine Arts) is well above his own average; his portrait of Stuart is the best one of that fascinating personality. He also painted a few landscapes; the only example now known is his "View on the Schuylkill" (Art Institute of Chicago).

See Virgil Barker, "John Neagle," *The Arts*, 8:7–23, no. 1 (July 1925). (Vl. B.)

NEALE, EDWARD VANSITTART (1810–1892), leader in the English co-operative movement and a Christian Socialist, was born at Bath on April 2, 1810, the son of a Buckinghamshire clergyman. He studied at Oriel college, Oxford, was called to the bar at Lincoln's Inn in 1837 and became a Christian Socialist in 1850. He founded the first co-operative store in London and advanced the capital for two builders' associations, both of which failed. On his own initiative he started the Central Co-operative agency, similar in many respects to the Co-operative Wholesale society of a later day. Also unsuccessful, this venture involved him in heavy financial loss. He was an early advocate of limited liability and company regulation, actively promoting the Consolidation act of 1862, and was associated with the movement that resulted in the Industrial and Provident Societies act of 1876. Besides publishing pamphlets on co-operation, he served on the executive committee that developed into the Central Co-operative board, took part in forming the North of England Co-operative Wholesale society in 1863 and promoted co-operative congresses, the first of them in 1869. He advocated close relations between co-operative associations in different countries. Neale died on Sept. 16, 1892. (A. Bri.)

NEANDERTHAL MAN. Human populations referred to as Neanderthal man inhabited much of Europe and the lands surrounding the Mediterranean during the extended time interval of the earlier Upper Pleistocene. The name derives from a gorge-like valley above the small stream of Düssel, a tributary of the Rhine, 7 mi. east of Düsseldorf, Ger. There in the Feldhofer cave in 1856 workers encountered portions of a human skeleton; 14 pieces were eventually salvaged by a professor at the *Realschule* in Elberfeld, Johann Carl Fuhlrott. Following the description of the remains (by Prof. H. Schaaffhausen) a lively controversy arose as to whether their unusual morphology was normal, and hence indicative of an archaic variety of man, or whether it was merely a case of pathology in modern man (*Homo sapiens*). The former view was duly proved correct, especially after the discovery in 1886 of two similar skeletons in the cave of Spy (Belgium) in association with implements of chipped stone and animal bones representative of a subarctic fauna including extinct species (or extant forms no longer in the region). In the course of over a century of research on human evolution and the prehistory of man much additional information has been gained concerning these peoples, their distribution in space and time, their origin and disappearance and their ways of life. Several distinctive populations of Neanderthal folk are now recognized. These populations differ in certain aspects of their skeletal anatomy as well as in their spatial and temporal distribution.

The first recognizedly Neanderthal peoples occur during the last half of the Last Interglacial stage, certainly in central and southeastern Europe and probably also in western Asia. Among other features they were characterized by moderately small cranial capacity; a short, narrow and well-arched skull vault; large but somewhat separate and curved supraorbital ridges; moderately large cheekbones with some hollowing beneath them; gracile and straight or only slightly curved limb bones, generally lacking enlarged ends. The general pattern of the anatomy of the face and even of the skull vault of these early Neanderthal peoples was not greatly unlike that of *Homo sapiens;* this was also true of the bones of trunk and limbs, although these are not very well known. There was nonetheless a complex of skeletal features which distinguished them from modern human populations.

Far more numerous and complete skeletal remains have been recovered of Neanderthal peoples from the succeeding initial phases of the Last Glacial stage. This is probably due in large part to the marked tendency toward utilization of cave fronts and rock shelters below cliffs for habitation sites, as well as the widespread practice of deliberate burial of the dead. Such peoples were distributed, evidently as small semi-isolated populations of relatively unsophisticated hunting and gathering bands with a Mousterian stone industry, from western Asia throughout much of Europe as well as along the Mediterranean littoral of northern Africa. (There is no evidence for such peoples either in Africa south of the Sahara or in eastern or southeastern Asia; however, broadly contemporaneous peoples in these areas have been sometimes referred to as Neanderthaloid since a number of features of their skull morphology simulate those found among Neanderthal peoples.)

Over most of this area of distribution such peoples resembled quite closely early Neanderthal populations of the preceding interglacial period. This was not the case with those groups, often called classic Neanderthals, occupying the western and southwestern periphery of Europe. Over this area, including Belgium and France and westernmost Germany, Spain and Italy, were short, stout, powerfully built Neanderthal peoples characterized by a number of distinctive skeletal characteristics which set them apart from their contemporaries elsewhere. This was true of the brain case (very large cranial capacity; long, low and wide skull vault, flattened behind; heavy biarched supraorbital ridges), of the face (projecting and large; rounded orbits; small cheekbones with no hollowing below them due to expanded sinuses; quite large teeth and palate), of the trunk (rounded broad chest; short vertebrae with large muscular processes; long slender collarbone) and of the limbs (heavy curved thigh and forearm bones; large feet and hands but short fingers and toes; arm and leg bones with enlarged ends; long heel bone). The popular conception that these people were slouched in posture and walked with a shuffling, bent-knee gait seems to have been due in large part to the faulty reconstruction of the skull base and to the misinterpretation of certain features of the limb bones of one of the Neanderthal skeletons discovered early in the 20th century.

Such were the peoples to whom the specific name *Homo neanderthalensis* was applied (by W. King in 1864) following the original discovery of the type skeleton in the Feldhofer cave. (Actually two other such skulls had been found earlier in the 19th century but went unrecognized until after the Neanderthal discovery proper.) It is now apparent, however, that these peoples represented merely the western periphery of a particular range of variation within a quite widespread human species. In fact, since such peoples were considerably like *Homo sapiens* the use of the distinct species name *neanderthalensis* may be most misleading; some workers think it might be applicable to the classic Neanderthals. It is likely that populations referred to as classic Neanderthals became relatively isolated from other such peoples in the southwesterly parts of Europe as a consequence of the increasing severity of the climate during the initial phases of the Last Glacial

stage. Such isolation would have greatly restricted gene flow between populations, would have increased inbreeding and would have tended to bring about shifts, even drift in gene frequencies, especially in certain directions because of the accidents of sampling resulting from the original population composition. Increased selection pressures under a progressively harsher environment may also have played a role, although this is still poorly understood. Since the time range of the Last Glacial is now largely within the limits of the radiocarbon (C^{14}) method of absolute dating, it is now possible to estimate the time involved in such evolutionary changes. The Last Glacial seems to have begun about $75,000 \pm 5,000$ years ago; a rather pronounced temperate interstadial amelioration began around 42,000 years ago and had a duration of about 10,000 years. The Neanderthals appear to have persisted fairly well into, perhaps almost to the end of, this interstadial; probably they had disappeared by about $35,000 \pm 3,500$ years ago. Hence the characteristics of the Neanderthals developed over a period of approximately $30,000 \pm 5,000$ years; *i.e.*, during $1,500 \pm 250$ generations.

The factors responsible for the disappearance of these and other Neanderthal peoples are unclear. In Europe nearly all cave and rock shelter sites where there was repeated human occupation reveal a sterile horizon between the last Neanderthal occupation (with Mousterian industry) and succeeding occupation by a Cro-Magnon variety of *Homo sapiens*, characteristically European in skeletal anatomy (with an early Upper Paleolithic industry). (*See* CRO-MAGNON MAN.) Hence it cannot be demonstrated conclusively whether these different human populations overlapped in time in the same territory, the indigenous Neanderthals being perhaps killed off by the immigrant anatomically modern peoples, or whether the Neanderthals were no longer present, presumably having already become extinct. In southwestern Asia there are several cave sites (Skhul and Qafzeh, in present-day Israel) where skeletal remains of fundamentally anatomically modern peoples, once regarded as a special variety of Neanderthal, have been found. These were broadly contemporaneous with other more typically Neanderthal folk. Some workers believe that the former, which were perhaps already coexisting with and were eventually to replace Neanderthals in southwestern Asia during the initial phases of the Last Glacial, represented the forerunners of the Cro-Magnon populations who later replaced the Neanderthals of Europe. *See* ANTHROPOLOGY; MAN, EVOLUTION OF. *See* also references under "Neanderthal Man" in the Index.

NEARCHUS (d. probably 312 B.C.), an officer in the Macedonian army under Alexander the Great. A native of Crete, he settled at Amphipolis in Macedonia. In 333 Alexander made him satrap of the newly conquered Lycia and Pamphylia. In 325, when Alexander descended the Indus to the sea, he ordered Nearchus to conduct the fleet to the head of the Persian gulf. Nearchus was then entrusted with the more difficult task of circumnavigating the Arabian peninsula from the mouth of the Euphrates river to the Isthmus of Heroönpolis (Suez), a project cut short by the death of the king (323). In the allocation of commands that followed immediately in 323 Nearchus obtained his former satrapies. In the subsequent struggles of the Diadochi or "Successors" of Alexander he took the side of Antigonus I (*q.v.*). He wrote a detailed narrative of his expedition, of which a full abstract was embodied by Arrian in his *Indica*. *See* also ALEXANDER III (the Great).

NEAR EAST: *see* MIDDLE EAST.

NEATH (CASTELL-NEDD), a metropolitan borough and industrial town in Glamorgan, Wales, pop. (1961) 30,935, lies on the river Neath or Nedd, 3 mi. from its mouth in Swansea bay and 37 mi. W.N.W. of Cardiff by road. The Vale of Neath, at the southwestern end of which the town stands, is a narrow valley running northeast from Neath for about 12 mi. with steep and lofty sides broken by small glens and waterfalls. It leads up toward the Brecon Beacons and Forest Fawr and is one of the most picturesque areas of south Wales; it has retained its beauty in spite of considerable industrialization. Although Neath is encumbered with many bleak industrial buildings, the centre of the town is pleasant, with flower beds in the public gardens and views of the hills.

The port of Neath is Briton Ferry (part of the borough since 1922), which has extensive steel and tinplate works and forms an unbroken urban continuity with Neath. The importance of Briton Ferry was enhanced by the carrying of a new road by viaducts across Briton Ferry dock and the mouth of the Neath, linking Cardiff and such towns as Bridgend, Margam, Port Talbot and Aberavon direct with Swansea and bypassing Neath itself.

Neath is a very ancient site, owing its strategic importance to its location on the river crossing and at the mouth of the Vale of Neath. The Roman fort of Nidum was established about A.D. 75 to 80 and protected the road from Caerleon to Carmarthen. Neath castle was built in the early 12th century and burned by Llewelyn ap Iorwerth in 1231; only its gateway remains. Neath abbey is an extensive 13th-century Cistercian ruin. The first known charter was granted to the town by Earl William of Gloucester, in the 12th century; other charters followed in 1280, 1340, 1359, 1397, 1421, and 1423, and the final charter was bestowed by James II in 1685. Serving as a market centre for a wide and prosperous countryside, Neath acquired further importance on account of local mineral resources and became a centre of the copper industry after a copper smelting works was established there in 1584 by Cornish miners. In the 17th century other nonferrous ores (as well as copper), for lead and silver extraction, were imported. After 1700 Swansea took up metal working and rapidly outpassed Neath as the most important Welsh port on the Bristol channel. Iron and coal figured largely in Neath's subsequent development and its modern economic importance is largely connected with the steel industry. Industrial establishments are mainly concerned with metallurgy and the production of metal goods. It has formed the nucleus of a small but substantial conurbation of industrial towns.

Exploration of the area around Neath reveals many contrasts between modern industrialization and the surviving monuments of ancient times. George Borrow, coming in 1854 upon Neath abbey with its gloomy smoke-ridden background, likened the scene to a "Sabbath in Hell." Southeast of Briton Ferry are Aberavon and Port Talbot, brought into being largely by the coal and iron of the Afon valley. And beyond these is Margam, celebrated on the one hand for its 13th-century Cistercian abbey with its exquisite chapter house and on the other for its huge modern steel plant (opened in 1951), with an annual capacity of 1,500,000 tons. For 8–10 mi. in this southeastern direction there extends from Neath through Briton Ferry an almost continuous industrial and urbanized landscape, and for a similar distance westward is the centre of the town of Swansea.

Local government in Neath is under a mayor and corporation. There are two railway stations and the town is an important road transport centre, though some of its traffic has been affected by the new Briton Ferry bypass. (HU. S.)

NEBRASKA, styled the "Tree Planter's state" by act of the legislature, 1895, and renamed the "Cornhusker state" by legislative act in 1945, is near the centre of the United States. It is bounded on the north by South Dakota, on the east by Iowa and a corner of Missouri, on the south by Kansas, on the south and west by a corner of Colorado and on the west by Wyoming. The Missouri river flows along the eastern and northeastern border. The extreme length of the state is 428 mi. and the extreme breadth 207 mi. The area is 77,227 sq.mi., of which 615 are water surface.

Nebraska was named the "Tree Planter's state" because Arbor day was originated there by J. Sterling Morton in 1872 and forestry was emphasized by the pioneers and their successors. The name "Cornhusker" originally was applied to the University of Nebraska football team. Nebraska was the 37th state to be admitted into the union, on March 1, 1867; the state capital is Lincoln. The state flower is the goldenrod, the state bird the western meadowlark and the state tree the American elm. The state flag consists of the state seal, which symbolizes commerce, industry, transportation and agriculture, and the state motto, "Equality before the law," in gold and silver, on a dark blue field.

PHYSICAL GEOGRAPHY

Physical Features.—The principal topographical feature of Nebraska, which lies approximately between 40° and 43° N. lat. and 95° and 104° W. long., is a great undulating plain, sloping gradually from the northwest to the southeast, at an average of ten feet per mile. This plain is broken along its northern and eastern borders by hilly regions. The highest point, 5,424 ft., is in Kimball county; the lowest point, 840 ft., is in Richardson county. The state's principal topographical regions are the loess, the sandhills, the high plains and the badlands, with lowlands along the Missouri and Platte rivers.

The loess region includes about 42,000 sq.mi. of excellent farmland in the eastern and south central parts of the state. The area is gently rolling except along the Missouri and Republican rivers and at some other points where moderate hills appear. The sandhills lie west and northwest of the loess region, with outliers extending to the southwest corner of the state. The main region of the sandhills includes about 18,000 sq.mi. and consists of low hills interspersed with rich valleys, lakes and fertile tablelands. The high plains, which lie west and northwest of the sandhills, include about 12,000 sq.mi. and consist of level stretches of tableland broken occasionally by deep canyons and rugged buttes. The region includes two areas of evergreen-wooded mountains, the Wild Cat range and the Pine Ridge. The badlands, used as rangeland, occupy about 1,000 sq.mi. in the northwest corner of the state.

The state is drained by the Missouri river, a navigable stream which skirts the eastern border for approximately 450 mi. The principal tributaries of the Missouri in Nebraska are the Platte and its branches; the Niobrara; the Republican; the Big and Little Blue; and the Big and Little Nemaha. The Platte is the dominant and characteristic river and with its tributaries drains more than half of the state. Its wide terraced valley, extending across the entire state and leading to mountain passes, made it an important highway across the continent. Its channel varies from one-half to one mile in width and is filled with islands. In the summer, use of water for irrigation leaves its middle course in the state entirely dry. The sandhills contain hundreds of small lakes, particularly the area near the headwaters of the Loup and the Elkhorn rivers, the Platte's principal tributaries. The recreational facilities provided by these lakes are augmented by reservoirs resulting from the construction of numerous multipurpose dams. Artesian water exists in at least ten different counties, and the sandhills provide a significant quantity of ground water, which is discharged into the lower Platte valley to supply irrigation wells.

Climate.—The climate of Nebraska is typical of the interior of large continents, and is characterized by light rainfall, low humidity, hot summers, cold winters and wide variations. The mean annual precipitation varies from 27.58 in. in the eastern part of the state to 12.65 in. in the western part. Wet and dry years run in irregular cycles. Fortunately for the state's agriculture, approximately two-thirds of the annual precipitation normally occurs in the crop-growing season, from April to August, inclusive. The mean annual temperature varies from 50.5° F. (about 10° C.) in the east to 48.3° F. (about 9° C.) in the west. The mean temperature for January is 22.5° F. in the east and 24.1° F. in the west; for July, it is 77° F. in the east and 73.8° F. in the west. The growing season between frosts varies from 164 days in the southeast to 122 in the northwest.

Soil.—A soil of remarkable fertility is Nebraska's fundamental asset. A soil map of Nebraska exhibits wide variations, which accounts in large measure for the diversified nature of its agriculture. The principal soil associations of the United States found in Nebraska—in which soils are grouped geographically rather than taxonomically—are prairie soils, chernozem soils, chestnut soils, alluvial soils, planosols, lithosols and sand. Except for the lithosols, which occur in the badlands, and the sand of the sandhills, these soils are extremely fertile and well suited to the production of cultivated crops.

Vegetation.—Grasses originally comprised the state's principal form of vegetation. Only about 3% of the state was forested, with trees occurring principally along the streams and on the low mountain ranges of the west. The grasses varied according to rainfall. In the more humid eastern part of the state, tall prairie grasses—particularly the bluestem—abounded; in the less humid western area, short grasses—notably grama and buffalo—were characteristic. Except in the range country of the central and western parts of the state, the grasslands have been converted to the production of cultivated crops.

Nebraskans have exhibited great interest in planting trees since pioneer days. Arbor day was first celebrated in Nebraska, and the Nebraska national forest in the sandhills is wholly man made. By the second half of the 20th century Nebraska still had only about 3% of its area in forest.

Animal Life.—The principal indigenous animals were those characteristic of the plains. Of these, the most plentiful was the bison, or American buffalo. Others found in great numbers were the pronghorn, mule deer, coyote, kit fox, jackrabbit, ground squirrel, prairie dog, skunk and, along the streams, the beaver. The porcupine, wood rat and red squirrel were found in the woodlands. Birds were plentiful and, in addition to hundreds of species of songbirds, included the prairie chicken, grouse and migrating waterfowl.

Historic Sites and Parks.—The principal historic sites in Nebraska are:

Homestead National Monument of America (created in 1939), located near Beatrice in Gage county, the site of Daniel Freeman's homestead, the first in the nation to be claimed, Jan. 1, 1863, under the Homestead act of 1862.

Chimney Rock National Historic Site (established 1956), in Morrill county, an important landmark on the overland trail.

Scotts Bluff National Monument (established 1919), in Scotts Bluff county, an important landmark on the overland trail; the Oregon Trail museum, associated with the monument, interprets the westward movement through the Platte valley.

Arbor Lodge State park, in Otoe county, the home of J. Sterling Morton, founder of Arbor day.

Ft. Kearny State park, in Kearney county, site of Ft. Kearny, an important military post and stage station on the overland trail.

Ft. Robinson, in Dawes county, an important military post during the period of the Indian wars on the northern plains, and the site where Crazy Horse, famed chief of the Sioux, was killed.

Ft. Atkinson, in Washington county, site of an early military post (1819–27) which furnished protection to the fur trade of the west.

Nebraska state parks, in addition to Arbor Lodge, Ft. Kearny and Ft. Robinson, are Chadron, Victoria Springs, Stolley, Niobrara and Ponca. The state game, forestation and parks commission, which supervises these areas, also maintains more than 50 lakes and recreation grounds.

HISTORY

Historical Development.—Francisco Vásquez de Coronado, the first white man to penetrate the northern plains, probably did not reach Nebraska in his fruitless search for the mythical kingdom of Quivira in the summer of 1541, but the Coronado legend has been incorporated into the literature and pageantry of the state. Approximately two and one-half centuries before 1803, when Louisiana territory, of which Nebraska was a part, was acquired by the United States, Spanish and French explorers and French fur traders occasionally entered the area that is now Nebraska. A small temporary trading post was erected by French

traders in 1795 in what is now northeastern Nebraska.

In the half-century following the Louisiana Purchase in 1803 explorers and fur traders made known to the public important facts about the region. Almost all of the early explorers were unfavourably impressed with the area, and their reports gave rise to the belief that it was little more than a desert and entirely unfit for agriculture.

The Platte valley, the state's most important topographic feature, developed into a significant thoroughfare to the Rocky mountains and the Pacific coast. It was first used by fur traders who, from 1824 until the decline of the fur trade in the 1840s, followed the Platte river route to and from the trapping grounds of the mountain region. Beginning in 1835 missionaries to the Oregon country followed the same route. In 1841 the first group of Oregon homeseekers went through the Platte valley, to be followed in succeeding years by thousands of emigrants over what came to be known as the Oregon trail following the south bank of the river. In 1847 the Mormons, led by Brigham Young, went along the opposite bank of the Platte en route to the valley of the Great Salt lake. They likewise were followed by many thousands in succeeding years. Gold seekers bound for California (1849–50) and Colorado (1859) added to the traffic on the trail.

Nebraska territory was organized in 1854, largely as a result of agitation for a transcontinental railroad. The name "Nebraska," deriving from an Oto Indian word for "flat water," had long been used to designate the Platte river and surrounding territory. The final Kansas-Nebraska bill, providing for two territories, became the centre of an intense struggle in congress between the north and south, involving the extension of slavery, the removal of Indians and rival routes for the proposed Pacific railway. The bill, signed by Pres. Franklin Pierce, May 30, 1854, provided that the new territories should be slave or free as voted by the citizens in each territory, thus reversing the policy regarding the extension of slavery established for the Louisiana territory by the Missouri Compromise (*q.v.*) of 1820.

Nebraska territory, as organized in 1854, included the vast region from 40° N. lat. to British America, and from the Missouri and White Earth rivers to the summit of the Rocky mountains. In 1861 and 1863 it was reduced by the creation of other territories to nearly its present boundaries.

Most of the early settlements were along the Missouri river. Bellevue (1823), the oldest permanent settlement, was important as a fur trading centre, as a missionary centre and in the administration of Indian affairs. Brownville, Nebraska City, Plattsmouth, Omaha and Florence, established in 1854, soon became important territorial towns. Omaha (*q.v.*) was the territorial capital. Other towns of the period included Beatrice, Columbus, Falls City and Fremont. The Pacific Railroad act and the Homestead act, both passed by congress in 1862, aided white settlement. The railroads were particularly significant to Nebraska in that they made settlement away from the Missouri river possible.

The great industry during the territorial period was transport by the overland trail. Over it ran freight wagons, stagecoaches and, in 1860–61, the famous pony express, whose services ended with the completion of the overland telegraph in the latter year. Trail transportation terminated in Nebraska with the construction of the Union Pacific railway in 1865–69.

After turning down statehood in 1860 and 1864, the voters in 1866 approved a constitution which had been drafted by the legislature, and on March 1, 1867, Nebraska was proclaimed the 37th state. The South Platte region, which had always opposed Omaha as the territorial capital, had a majority in the first state legislature of 1867 and passed an act providing for the relocation of the capital, to be named Lincoln, in that section. On Aug. 14, 1867, the capital commission, appointed by the legislature, located the capital at the little village of Lancaster and renamed it Lincoln (*q.v.*). Railroad and cow towns grew up at Grand Island, Hastings and Kearney (*qq.v.*) in the 1870s and at Alliance, Chadron and Norfolk in the 1880s.

The Democratic party was the sole political party in Nebraska from 1854 to 1858. The Republican party won control in 1860 and retained it firmly until 1890. In that year the Farmers' alliance organized the People's Independent or Populist party. A three-cornered fight resulted in the Democrats' getting the governorship and the Populists a majority in the legislature. By fusing with the Democrats under the leadership of William Jennings Bryan, the Populists won victories in 1894, 1896 and 1898. The Populist party died out after 1900, and political control fluctuated between the Democrats and the Republicans until 1930. During the 1930s the Democrats dominated the state although George William Norris, nominally a Republican, remained in the U.S. senate from 1913 to 1943. The Republicans asserted control in 1940 and remained in the ascendancy until 1958 when the Democrats returned to power, electing a governor and two congressmen In 1960, 1962 and 1964 the Democrats also elected the governor, the Republicans recapturing the governorship in 1966.

POPULATION

Nebraska's population grew rapidly from 28,841 in 1860 to 1,058,910 in 1890. After 1890 growth was slow, and between 1930 and 1940 the population declined from 1,377,963 to 1,315,834. In 1950 the population was 1,325,510, an increase of 0.7% over the population in 1940, and in 1960 the population was 1,411,330, an increase of 8.7% over that of 1950. The population per square mile in 1960 was 18.3, as compared with 49 7 for the United States.

*Nebraska: Places of 5,000 or More Population (1960 Census)**

Place	Population				
	1960	1950	1940	1920	1900
Total state	1,411,330	1,325,510	1,315,834	1,296,372	1,066 300

York	6,173	6,178	5,383	5,388	5,132

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

During the period of rapid growth (1860–90) there was a heavy immigration of foreign born into the state, particularly from Germany, Sweden, Bohemia, Ireland and Denmark. In 1960, 2.9% of the population was foreign born. Of the foreign-born population, 27.0% was born in Germany, 8.9% in the United Kingdom and 8.0% in Czechoslovakia. The nonwhite population, mostly Negro, constituted 2.6% of the total.

Of the 1960 population, 54.3% was classified as urban, as compared with 46.9% in 1950, 39.1% in 1940 and 35.3% in 1930. Of the 93 counties, 23.7% showed an increase in population between 1950 and 1960, as did all of the cities of 10,000 or more population. The percentage of the population which was under 14 years of age increased from 26.4% in 1950 to 29.4% in 1960; the percentage over 65 years of age increased from 9.9% in 1950 to 11.6% in 1960.

GOVERNMENT

Administration.—A constitution adopted in 1875 and revised by a constitutional convention in 1919–20 is the basis of Nebraska's government.

The general election, state and local, is held in even-numbered years on the first Tuesday after the first Monday in November, but municipal and school district elections may be held at other times. Judges, regents of the state university, members of the legislature and some municipal officers are elected on nonpartisan ballots.

The governor, chief executive officer of the state, is chosen by direct vote of the people, as are the lieutenant governor, secretary of state, auditor, treasurer and attorney general. Constitutional amendments in 1962 provided for four-year terms for the governor and lieutenant governor. The other four officers elected at large serve two-year terms. The governor appoints, with legislative approval, heads of the code departments, members of boards and a few other officers. He fills vacancies in state offices arising from death, resignation or removal.

The unicameral legislature of Nebraska is unique among state governments. Beginning in 1937 in accordance with an amendment adopted in 1934, it consisted of a single house of 43 nonpartisan legislators representing geographic areas that had about equal population in 1935. In 1965 it was reapportioned under federal court orders with 50 members allocated on a strict population basis, giving greater representation to urban areas. The chamber is presided over by the lieutenant governor. The legislature meets biennially in the odd-numbered years, and there is no limit on the length of the sessions.

Administration of justice is vested in a supreme court, 18 district courts, county courts, municipal courts and justice courts. In 1962 the voters approved a constitutional amendment adopting the Missouri plan of judicial selection and tenure. Under this plan the governor fills vacancies from a list of nominees compiled by a commission of lawyers and laymen. The judges so appointed run on a nonpartisan ballot for election to subsequent terms. The supreme court consists of six associate justices and one chief justice. Each district court consists of from 1 to 9 judges (total number 35). County courts have one judge. Lincoln and Omaha have municipal courts. Provision is made for approximately 2,000 justice courts. The district court is the court of general, original, legal and equity jurisdiction. The jurisdiction of county, municipal and justice courts is limited. Appeal to the supreme court, the court of last resort, may not be denied in any case.

Of the 93 counties, 28 are of the township or supervisor type, governed by a board of supervisors of seven members, and 65 are of the precinct or commissioner type, governed by boards of commissioners of three or five members. There are about 100 incorporated cities and 400 incorporated villages. Two cities are governed by the commission plan, one by a modified commission plan, nine by the city-manager plan and all others by the mayor-council form of government. Government of villages is vested in a board of trustees consisting of five members elected by popular vote. Any city with a population of 5,000 or more may adopt a home-rule charter, although only Omaha, Lincoln and Grand Island have done so.

Other governmental subdivisions include 5 public power districts, about 40 rural electrification districts and almost 500 other units, including drainage districts, irrigation districts, reclamation districts, weed eradication districts, soil conservation districts, metropolitan utilities districts and rural fire protection districts.

Finance.—Nebraska has no state income tax and no general sales tax. The general property tax, established in 1867, is supplemented by taxes on corporations, gasoline, liquor and cigarettes, by state licences and fees and special taxes, and by contributions from the U.S. treasury. The state has no bonded debt.

EDUCATION

State School System.—Nebraska has provided free public education since 1855. Most of the support and control comes from the local school districts. From 1869 to 1955 the state exercised general supervision of education through a superintendent of public instruction, an elected official. In 1955, as the result of a constitutional amendment adopted in 1952, this supervision was transferred to the state department of education, consisting of an elected board of education and a commissioner of education appointed by the board.

The local school districts provide approximately 90% of the support of public schools, primarily from the general property tax. The remaining support is derived from educational lands and funds, state aid by direct appropriation and federal aid. In 1949 Nebraska made an effort to reduce the number of school districts in the state. As a result of these efforts, within ten years the number of districts declined from more than 6,500 to fewer than 4,500. At the same time, school expenditures increased more than 70%; enrollment increased almost 20%; and the number of teachers increased about 17%. Approximately 14% of the children in the state attend parochial schools.

Colleges and Universities.—The University of Nebraska, at Lincoln, established in 1869 and opened in 1871, is the state's principal institution of higher education. It is governed by a board of six regents elected by districts on nonpartisan ballots for six-year terms. The university consists of ten colleges and three schools, as follows: colleges of agriculture, arts and sciences, business administration, dentistry, engineering, graduate, law, medicine (at Omaha), pharmacy and teachers; and schools of fine arts, journalism and nursing. The university also maintains a school of agriculture at Curtis, and agricultural experiment stations at North Platte, Valentine and Alliance.

The four state teachers colleges became state colleges in 1963: they are Peru State college (established 1867); Kearney State college (1905); Wayne State college (1909); and Chadron State college (1911). Other publicly supported institutions of higher education are: Municipal University of Omaha, supported by the city of Omaha; and junior colleges at Fairbury, McCook, Norfolk and Scottsbluff, supported by local school districts.

The privately supported colleges and universities are: Concordia Teachers college, at Seward; Creighton university, at Omaha; Dana college, at Blair; Doane college, at Crete; Duchesne College of the Sacred Heart, at Omaha; Hastings college, at Hastings; Midland Lutheran college, at Fremont; Nebraska Wesleyan university, at Lincoln; College of St. Mary, at Omaha; and Union college, at Lincoln.

HEALTH, WELFARE AND CORRECTIONS

Nebraska's original Board of Health law was enacted in 1891. It was amended over the years, and in 1953 the legislature created a seven-member board of health appointed by the governor. The board of health has responsibility for maternal and child health, local health services, preventive medical services, communicable disease control, venereal disease control, dental health, tuberculosis survey, public health nursing, public health education, laboratories, sanitation, vital statistics, hospitals, cancer control, mental health, poliomyelitis control, athletics and examining boards. There were fewer than 100 hospitals in Nebraska at the end of World War II; the number was increased by more than one-third in a ten-year period.

The board of control was replaced in 1961 with a department of institutions and a department of welfare, each with its own director but having one overall advisory board. The state's charitable, educational and penal institutions, of which there are 17, include the Girls' Training school, Geneva; Home for Children, Lincoln; School for the Blind, Nebraska City; School for the Deaf, Omaha; Orthopedic hospital, Lincoln; Hastings State hospital; Lincoln State hospital; Norfolk State hospital; Nebraska Psychiatric institute, Omaha; Central Nebraska Mental Hygiene clinic, Hastings; state home, Beatrice; state penitentiary, Lincoln; state reformatory, Lincoln; state reformatory for women, York; Soldiers' and Sailors' home, Grand Island; and Hospital for the Tuberculous, Kearney.

The department of welfare administers child welfare services, crippled children's services, surplus commodity distribution and the programs of old age assistance, blind assistance, aid to dependent children and aid to the disabled.

THE ECONOMY

Living Conditions.—Nebraska, with relatively few mineral resources, has traditionally been an agricultural state. During and after World War II, however, there began a decline in the percentage of the labour force employed in agriculture, and by the second half of the 20th century about 26% was so employed. Of those not employed in agriculture about 28% was employed in trade, 20% in government, 16% in manufacturing and 11% in transportation. Total annual personal income of Nebraskans was

more than $2,500,000,000 as compared with $811,000,000 in 1929. In "constant" dollars, the income was approximately twice as great as that in 1929.

Production.—Although agriculture's relative importance declined in the years following World War II, it remains Nebraska's single most important economic activity. Livestock and livestock products normally account for approximately 70% of the gross cash income from farm marketings, which, in the years following World War II, usually were about $1,000,000,000. Cattle constitute the most important source of income from livestock. Other livestock include swine, sheep, poultry, horses and mules. Corn is the most important crop and wheat is the second most important. Other crops are oats, barley, rye, hay, sorghum, sugar beets and potatoes. The number of farms decreased from 121,000 before World War II to 101,000 in a 15-year period, while, at the same time, the average size increased from 391.1 ac. to 470.9 ac.

During the first half of the 20th century the steady progress of irrigation was of particular significance for Nebraska's agriculture, notably in combating the adverse effects of light rainfall. Water for irrigation is furnished by streams, of which the Platte, Loup, Niobrara, Republican and Elkhorn rivers are the most important, and by wells. By the second half of the 20th century more than 1,600,000 ac. were irrigated.

Nebraska's leading manufacturing activity consists of the conversion of the raw products of agriculture into marketable commodities. Other manufactures include fabricated metal products, machinery, precision instruments, apparel, lumber products, chemicals and plastics, and stone, clay and glass products. There are about 1,500 manufacturing establishments in the state, and the value added by manufacture is about $500,000,000 annually.

On Nov. 1, 1939, oil was discovered in Richardson county; in July 1949 oil was discovered in Cheyenne county. The state produced 1,800 bbl. of oil in 1939 and more than 20,000,000 bbl. in the 1960s. Natural gas was first produced in the state in 1951.

Trade and Finance.—Trade is second to agriculture as a factor in Nebraska's economy. Omaha and Lincoln are centres of wholesale trade for a large area. Numerous state and national banks and a larger number of domestic and foreign insurance companies conduct their business in Nebraska.

Transportation and Communication.—Missouri river navigation was a leading method of transportation until the construction of the railroads in the 1870s, when river traffic declined to almost nothing. During the 1940s, 1950s and 1960s it revived to a position of greater tonnage, if not greater relative importance, than in the earlier period. Ten trunk railways radiate from Omaha, five of them with a network of feeders over the state. Railway mileage was about 5,700 mi. in the second half of the 20th century, as compared with more than 6,000 mi. in 1930. There were numerous airports, many of them for public use, and scheduled local air service was extended to all parts of the state.

The most important transportation development in Nebraska in the years 1920–60 of course was the great extension of improved highways, accompanied by a rapid increase of motor vehicles.

Radio broadcasting began in 1921, and the first television station began operations in 1950. There are 20 daily newspapers and more than 250 weekly newspapers. The headquarters of the U.S. strategic air command are located near Omaha.

BIBLIOGRAPHY.—James C. Olson, *History of Nebraska* (1955), has "Suggested Readings" at the end of each chapter, which include the principal sources of information about the state; Nebraska State Historical Society, *Proceedings and Collections* (1885 *et seq.*), *Nebraska History* (1918 *et seq.*); *Nebraska Blue Book* (biennial, 1915 *et seq.*) is particularly valuable on government; Federal Writers' Project, *Nebraska: a Guide to the Cornhusker State* (1939).

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures are summarized annually in the *Britannica Book of the Year*, American edition. (J. C. O.)

NEBRIJA, (ELIO) ANTONIO DE (ELIO ANTONIO MARTINEZ DE JARAVA (1444?–1522?), Spanish humanist, was the author of the first grammar of a modern European vernacular language (*Arte de la lengua castellana*, 1492). Born at Lebrija, Andalusia, he signed his Latin works "Aelius Antonius Nebrissensis." As professor at Salamanca (1476–87; 1505–13), he reformed the teaching of Latin; he was also professor at Alcalá de Henares (1513–22). His Latin grammar, *Introductiones latinae* (1481), was in use in Spain up to the 19th century, and his *Dictionarium* (1492, Latin-Spanish; Spanish-Latin, *c.* 1494) and Latin-Catalan, Catalan-Latin *Vocabulario* (1507) are of primary importance in the development of Spanish lexicography. He was an editor of the Complutensian Polyglot Bible of Cardinal Francisco Jiménez de Cisneros (*q.v.*).

MacCrie, *History of the Progress and Suppression of the Reformation in Spain* (1829); F. Gonzales Olmeda, *A. de Nebrija* (1942). (S. G. G.)

NEBUCHADREZZAR (Babylonian NABU-KUDURRI-USUR, "The god Nabu has guarded the estate [succession]") was the name of two kings of Babylon.

NEBUCHADREZZAR I (reigned 1124–1103 B.C.) invaded and defeated Elam. His victory was so complete that the power of the hill peoples was broken for many years. For a time he was suzerain of Assyria.

NEBUCHADREZZAR II (the Nebuchadnezzar of the Old Testament) was the eldest son of Nabopolassar, founder of the Chaldean dynasty in Babylonia. He reigned from 605 to 562 B.C. In 605 B.C., as crown prince, he defeated the Egyptians under Necho II at Carchemish and won all Syria and Palestine. On hearing of his father's death, he hurriedly returned to Babylon, where he was enthroned on Sept. 6, 605 B.C. Despite the setback of a defeat by Egypt in 601 B.C., he vigorously pursued a policy of gaining full control in the west. He laid siege to Tyre for 13 years and punished Judah for its defection by capturing Jerusalem on March 16, 597 B.C. Jehoiachin was taken captive to Babylon with many Jews, and Mattaniah-Zedekiah was made king in his place (*see* JEWS).

In the following year Nebuchadrezzar fought a battle with Elam and in 595 B.C. mastered a revolt in his own country. The Babylonian chronicle, a primary historical source, is lacking after his 11th year and events must be reconstructed mainly from the Old Testament. Zedekiah rebelled in 589 B.C., and Nebuchadrezzar initiated a series of expeditions in which Lachish was captured and Judah devastated. Finally Jerusalem was sacked in 587 B.C. Five years later another expedition was conducted against Judah and the Arabs. A fragmentary text implies that Nebuchadrezzar invaded Egypt in his 37th year.

Nebuchadrezzar married Amytis, daughter of Astyages of Media, and in her honour built the "hanging gardens" at Babylon. His peaceful activities were primarily devoted to the embellishment of the capital (for a description of which *see* BABYLON). His building inscriptions from Babylon, Borsippa, Sippar, Marad and other cities, with many economic documents dated in his reign, have been published. Nebuchadrezzar died in Aug. or Sept. 562 B.C.

The title of Nebuchadrezzar was also assumed by two usurpers in the reign of Darius I. Nidintu-Bel (NEBUCHADREZZAR III) ruled at Babylon from Sept. 522 B.C. until his death three months later. In August of the following year a revolt by Araka led to his recognition as king of Babylon (NEBUCHADREZZAR IV) until his defeat and capture by the Persians on Nov. 27.

NEBULA, in astronomy, is a traditional term used to describe any cloudy or misty celestial object that remains fixed among the stars. Nebulae may be bright or dark, but they are generally nonstellar, luminous patches. Compared with stars, nebulae appear much fainter, because their spread-out light is more difficult to see than a point source. Thus, although there are about 5,000 naked-eye stars, only four nebulae are visible to the unaided eye. These are the two Magellanic Clouds in the southern hemisphere, and the two great spiral nebulae in the northern constellations of Andromeda and Triangulum.

Like the stars, nebulae are virtually innumerable, for their number depends upon the limiting brightness to which they are

recorded. Many hundreds are known in the Milky Way, or the galaxy. These are the galactic nebulae, masses of gas and dust associated with, and between, the stars of our own stellar system. Beyond the Milky Way are the extragalactic nebulae, entire stellar systems comparable to the galaxy, which populate the universe by the hundreds of millions. For both galactic and extragalactic nebulae, powerful telescopes employing photography are required for effective study (*see* PHOTOGRAPHY, CELESTIAL).

On the average, extragalactic nebulae have a luminosity 800,000,000 times that of our sun, the faintness of their light as we see it being due to the immensity of the distance it travels. Whereas light rays from the moon reach the earth in 1⅓ sec., those from the nearest extragalactic nebula, the large Magellanic Cloud, require 150,000 years for the journey. The most remote, observable extragalactic nebulae are estimated to be at distances of 5,000,000,000 light-years. Thus modern astronomy, in dealing with the feeblest extragalactic photons, explores with light as ancient as the oldest rocks on earth.

A widely accepted cosmological hypothesis assumes that the universe originally consisted of a small, compact mass, and that an explosion occurred approximately 10,000,000,000 years ago, thrusting the extragalactic nebulae outward in all directions. The astronomical data on which this expanding-universe theory is based are summarized in later sections of this article. (*See* also COSMOGONY.) The earth, its fellow planets and our sun—the solar system—belong to the galaxy, which is similar in form to vast numbers of spiral nebulae. As seen from another galaxy, our solar system would be located, but much too faint and small for detection, near the outer rim of the galaxy. Our sun makes a complete revolution in the galaxy in the cosmic equivalent of a year—about 200,000,000 solar years.

This article is divided into six main sections as follows:

I. HISTORICAL

Earliest Records.—Historical records of luminous patches in the sky are known to go back to Hipparchus (fl. 146–127 B.C.), who included in the earliest known star catalogue entries for the double star cluster in Perseus (h and χ Persei) and for the "Beehive" star cluster in Cancer (Praesepe). Nearly 300 years later Ptolemy (*c.* A.D. 140) listed five "cloudy stars" in his *Almagest*, but these objects, apparently nebulous to the eye, are in reality star clusters. The earliest known record of a nebula, as distinguished from a star cluster, is the one for the Andromeda nebula given by Al Sûfi (903–986) in his *Book of the Fixed Stars*, epoch 964. The spiral in Andromeda thus shares with the Magellanic Clouds the distinction of being one of the three nebulae discovered before the invention of the telescope. The Clouds of Magellan, which become visible to travelers to the southern hemisphere soon after the Torrid zone is entered, were known to the Portuguese navigators of the 15th century, and although not discovered by Magellan, the clouds are by common consent associated with his name to honour the great circumnavigator. Soon after the first use of the telescope on celestial objects in 1609 by Galileo (1564–1642), the Orion nebula was discovered in 1610 by the famous French patron of science Nicholas Peiresc (1580–1637). The Jesuit priest Cysatus (1588–1657), who began to survey the sky with a telescope in 1611, also discovered the same nebula (1618). It was Christiaan Huygens (1629–95), however, who not knowing of the earlier discoveries by Peiresc and Cysatus, gave in 1656 the first description and sketch of the brightest part of the Orion nebula. The Andromeda nebula also was soon rediscovered after the invention of the telescope, in 1611 by Simon Marius (1570–1624) who described it in the oft-quoted poetical words, "Like a candle seen at night through a horn."

Early Catalogues.—The first attempt to catalogue nebulae seems to have been made in 1715 by Edmund Halley (1656–1742), who listed six "luminous spots or patches," among them the globular star cluster in Hercules, which he had discovered in 1714. The next list, in this case of 16 "nebulous stars," was given in 1733 by the English divine W. Derham (1657–1735), apparently as a result of some observations he made in 1732, with a reflecting telescope, of such objects included in an earlier (1690) work by J. Hevelius (1611–87). In the first extensive survey of the southern skies made at the Cape of Good Hope in the years 1751–53 by Nicolas Louis de Lacaille (1713–62), a total of 42 nebulae were observed and then described in another significant list of such objects published in 1755. Shortly thereafter, another Frenchman, Charles Messier (1730–1817), while following the comet of 1758–59, noticed a nebulous object near the third-magnitude star

GREAT SPIRAL NEBULA (N.G.C. 598) IN THE NORTHERN CONSTELLATION OF TRIANGULUM, ONE OF THE FOUR NEBULAE VISIBLE TO THE NAKED EYE. HERE AS PHOTOGRAPHED WITH THE 48-IN. SCHMIDT TELESCOPE AT THE PALOMAR OBSERVATORY, CALIF.

ζ Tauri. His discovery, later to be called the "Crab" nebula in Taurus, is now known to be the expanding gaseous remnant of the 1054 supernova (*see* NOVA AND SUPERNOVA). Messier, although much more interested in comets—Louis XV nicknamed him the "ferret of comets"—found that his searches could be more efficiently prosecuted if he noted the positions of those apparently cometary objects that did not move among the stars. In this way Messier discovered most of the brighter nebulae and clusters visible from northern latitudes, and his final catalogue published in 1781 contained 103 entries.

The Catalogues of William and John Herschel.—The foregoing early catalogues of nebulae almost pale into insignificance, however, when compared with the systematic sweeps of the skies made by William Herschel (1738–1822) and his son John

Herschel (1792–1871). With a reflector of his own making, the elder Herschel began his illustrious career as the founder of sidereal astronomy by observing the Orion nebula in 1774. Its appearance so amazed him that he directed his attention to other nebulae, which then became objects for his lifelong study and interpretation. Between 1786 and 1802 he discovered and catalogued, in three lists, more than 2,500 nebulae. The younger Herschel proved to be his father's ablest successor in the field of nebular observation and discovery. Like his father, he constructed in 1820 his own telescope, an 18-in. speculum metal reflector, and began in 1825 to reobserve many of the nebulae found by his parent. The outcome of this second survey was a catalogue of about 2,300 nebulae, of which 525 were new. John Herschel found the field so fascinating that he resolved to extend his search to southern skies, and in 1834 he began on Table mountain near Cape Town, S.Af., a four-year survey that marked a new era in the study of celestial objects visible in the southern hemisphere. The Magellanic Clouds were for the first time subjected to a detailed examination, with the result that the larger one was found to contain more than 900 member star clusters, nebulae and stars associated with nebulosity, while nearly 250 similar objects were counted in the smaller cloud. The younger Herschel catalogued more than 1,700 other nebulae in southern skies, and for a number of them he made beautiful drawings. Upon his return to England in 1838, he set about systematizing all his own and his father's discoveries of nebulae, and his labours culminated in the "General Catalogue" of about 5,000 entries published in 1864 in the *Philosophical Transactions of the Royal Society*. This great work forms the backbone of J. L. E. Dreyer's *New General Catalogue of Nebulae* (N.G.C.) (1888), which augmented by the *First* (1895) and *Second* (1908) *Index Catalogues* (I.C.), with a combined total of more than 13,000 entries, constitutes the standard reference list for nearly all modern observations of nebulae.

II. DEVELOPMENT OF NEBULAR PHOTOGRAPHY

The invention of photography and its application to astronomy revolutionized the study of nebulae. Since the photographic emulsion has the advantage over the human eye of being able to accumulate the effect of exposure to faint light, it is therefore possible by prolonged exposure—limited mainly by the nocturnal airglow of the earth's atmosphere—to photograph nebular detail far too fine and faint to be seen visually with a telescope. Moreover, a photograph provides a permanent record that in most cases can be measured with a much higher precision than can be obtained by simple visual methods. These advantages were exploited by astronomers as soon as the practicable dry plate became available during the last quarter of the 19th century.

Early Photographs to 1900

The Orion nebula has the distinction of being the first one to be photographed on Sept. 30, 1880, by Henry Draper (1837–82), a New England physician. Its priority as a subject doubtless was due to its brightness, which would make it visible to the unaided eye were the nebula not outshone by the involved third-magnitude group of four stars known as the Trapezium (θ Orionis). In any case, the Orion nebula was popular with pioneers, for it was also photographed in France in 1881 by P. J. C. Janssen (1824–1907) and in England in 1883 by A. A. Common (1841–1903), who was doubly venturesome by doing nebular photography with a series of silver-on-glass reflectors, up to mirror diameters of 60 in. The Pleiades nebulosity was first photographed in its brightest parts around the stars Merope and Maia by the

THE OBSERVATIONAL BASIS OF THE EXPANDING UNIVERSE

Left: Cluster of extragalactic nebulae in Corona Borealis. This cluster of several hundred nebulae is typical of those in which apparent brightness measurements are made to estimate the greatest astronomical distances, in this case 400,000,000 light-years. The arrow points to one of the brighter members whose spectrum was photographed to determine the red shift of its spectrum lines, as indicated in the central part of the chart at the right

Right. Direct (left) and spectrum (right) photographs of extragalactic nebulae. The direct photographs indicate the decrease in size and apparent brightness as distance increases. The right-hand column shows corresponding nebular spectra, with arrows to indicate the displacement toward longer wave lengths (red) of the principal feature, the H and K lines of calcium. These red shifts, when interpreted as motions of recession and plotted against distance, give Hubble's velocity-distance relation, which is the empirical basis for theories of the expanding universe

brothers Paul and Prosper Henry, at Paris in 1885. About the same time in England, Isaac Roberts (1829–1904) with a 20-in. reflector began a pioneering program in nebular photography that for the first time revealed the true form and extent of many nebulae. His photograph in 1886 showed that the Pleiades cluster stars are enmeshed in complex clouds of wispy filaments, and that the Andromeda nebula has a spiral structure. This last result from a small reflector was a striking example of the power of photography because the first discoveries of spiral nebular forms, made visually in 1845–50 by Lord Rosse (1800–67) and his associates at Parsonstown, York, required the use of large speculum metal mirrors, up to six feet in diameter.

It was J. E. Keeler (1857–1900), however, who firmly established the great advantages of nebular photography with a reflector. In 1898–1900 at the Lick observatory, on Mt. Hamilton, Calif., where more favourable observing conditions existed than in England, he expertly improved and operated Common's 36-in. reflector that had been donated in 1895 to the first great mountaintop observatory by Edward Crossley (1841–1905) of Halifax, Eng. Keeler's photographs recorded in finer detail hundreds of previously unknown faint nebulae beyond the bounds of the Milky Way. From study of these plates, he drew two conclusions of prime importance: (1) the number of such nebulae photographable with his equipment was at least 120,000, compared to the catalogued number of less than 13,000; (2) most of these nebulae would show a spiral form.

Star Cameras.—It was also at the Lick observatory that E. E. Barnard (1857–1923) began in 1889 his epochal photography of the Milky Way with short-focus, large-aperture portrait lenses. These wide-angle cameras disclosed as no conventional telescopes could the immense richness and structural features of the clouds of stars, gas and dust that make up the galaxy. Likewise for the first time, dark nebulae appeared in a profusion of sizes and shapes on Barnard's photographs, and his systematic study of them opened a new field for modern astronomy: interstellar matter. Others quickly adopted this efficient survey technique, notably H. C. Russell (1836–1907) at Sydney, Austr., in 1890, and Max Wolf (1863–1932) at Heidelberg, Ger., in 1891. Russell's work on the southern Milky Way supplemented Barnard's in the north, while Wolf, pioneering in the photographic charting of the extragalactic nebulae, found the first rich cluster of these objects in Coma Berenices.

Nebular Photography After 1900

Thus nebular photography began to develop by two dissimilar techniques. One was with wide-field, lens-type star cameras (astrographs), the other with small-field reflectors. The two types were the astronomical analogues of the shotgun and rifle, with photography in the role of gunpowder. Also, the beginning of the 20th century marked a world-wide mushrooming of construction and operation of both types of photographic telescopes, which increased steadily in size and number as advances were made in optics and engineering.

The Harvard College observatory, Cambridge, Mass., probably led the field in exploiting the advantages of star cameras for nebular photography. Starting about 1900 in the southern hemisphere first at Arequipa, Peru, and after 1927 at Bloemfontein, S.Af., Harvard astronomers used the largest star camera—the 24-in. Bruce—to chart the distribution of nebulae over large areas in southern skies, and to study in detail those extragalactic bonanzas, the Magellanic Clouds. At their northern station on Oak Ridge, Mass., similar work was done with a battery of star cameras ranging in size from a few inches in aperture up to the 16-in. Metcalf. Carried out under the general direction of Harlow Shapley from about 1930–50, these photographic surveys have yielded an immense amount of information on the extragalactic nebulae.

Reflectors.—At the Mount Wilson observatory, Pasadena, Calif., the reflecting telescope was developed to its potential peak of perfection, along with accessory instrumentation that has immeasurably increased our knowledge of both galactic and extragalactic nebulae. It was there that G. W. Ritchey (1864–1945) figured to the highest optical quality the first large telescope mirror, which he also used under the most favourable conditions from 1909–17 in the 60-in. Mount Wilson reflector. His nebular photographs set a new standard in photographic definition, with the result that a few of the largest and nearest spiral nebulae were resolved into their brightest stars. G. E. Hale (1868–1938), who had few peers in the perception of the value of more powerful instruments to attack fundamental astronomical problems, was able in 1919 to place in successful operation on Mt. Wilson a 100-in. reflector. Programs of nebular research with this great telescope have produced a rich harvest of results, especially for the extragalactic nebulae. With it, Edwin Hubble (1889–1953) discovered in 1923 the first Cepheid variable in the Andromeda nebula, M. L. Humason began in 1928 his measurement of large red shifts (see *Red Shifts and Expansion of the Universe,* below) in the spectra of extragalactic nebulae, and W. Baade in 1944 resolved into stars the amorphous nuclear region of the Andromeda nebula. Thus to this one telescope we owe three of the most significant observational advances in modern astronomy: (1) the first true idea of the scale of the universe, from Hubble's work on the distances and real brightnesses of extragalactic nebulae; (2)

REFLECTED AND SCATTERED STARLIGHT OF THE PLEIADES (M45), GALACTIC NEBULA IN THE CONSTELLATION OF TAURUS, 490 LIGHT-YEARS FROM THE EARTH. STARS IN THE CLUSTER PROVIDE THE LIGHT, AND SURROUNDING CLOUDS OF FINELY DIVIDED DUST PARTICLES REFLECT AND SCATTER THE RAYS FROM THE STARS. 48-IN. PHOTOGRAPH

the concept of an expanding universe, from the velocity-distance relation based on Hubble's distances and Humason's red shifts; and (3) the recognition of two distinct stellar populations of different age and evolution, from Baade's synthesis of highest-fidelity photographs in blue and red light.

Modern Developments.—Among the many large and modern star cameras, the 20-in. Carnegie astrograph at the Lick observatory deserves special mention. Installed in 1939, its basic program proposed by W. H. Wright was to provide a set of first-epoch

VEIL NEBULA (N.G.C. 6992 AND 6995) IN CYGNUS, A NORTHERN CONSTELLATION. THE NEBULA GLOWS AS IT COLLIDES WITH DUST AND GAS IN INTERSTELLAR SPACE. HOT BLUE LIGHT IS EMITTED FROM THE LEADING EDGE OF THE NEBULA WHERE THE HARDEST COLLISIONS OCCUR; LESS ENERGETIC COLLISIONS IN THE TRAILING EDGE CAUSE A RED GLOW. 48-IN. SCHMIDT PHOTOGRAPH

photographs of the northern two-thirds of the sky, for the most accurate measurement of galactic stellar motions with respect to the background of faint extragalactic nebulae. The full set of 1,246 plates was obtained in 1947–54 by C. D. Shane and C. A. Wirtanen who began in 1948 to count the several millions of extragalactic nebulae recorded. Although this set of plates maps the sky with high precision to about the 19th magnitude, its quality as a photographic sky atlas cannot compare with that obtained by a new type of star camera.

The Schmidt Telescope.—Invented about 1930 by Bernhard Schmidt ([illegible]–1935) at the Hamburg observatory, Bergedorf, Ger., the optical system that bears his name has revolutionized nebular photography. With pure genius, he placed a thin, weakly curved, aspherical lens at the centre of curvature of a spherical mirror, and in this simple but elegant way produced an optical system that would have high speed, large field and nearly colour-free images. This was a major advance in optics, and its rapid introduction in astronomy is due in large measure to Schmidt's colleague Baade, who fully realized the importance of the discovery when he came to the Mount Wilson observatory in 1931. At that time plans and programs were being made for a 200-in. reflector, and it was decided to build an 18-in. Schmidt camera as a pilot model survey instrument. Its immediate success led to the design, and construction after World War II, of the 48-in. Schmidt telescope on Palomar mountain. Its performance tests in 1948–49 so far exceeded all previous wide-field, faint-limit photographs that its first program was to survey all the sky observable from the northern hemisphere. From 1949–56, under the joint sponsorship of the National Geographic society and Palomar observatory, the 48-in. Schmidt was used to obtain the 879 plate-pairs—one exposure in blue light and one in red light—in this finest of all photographic sky atlases. Carried out under the critical supervision of R. Minkowski, this survey by the 48-in. Schmidt has recorded so much new information on nebulae that it will serve as a prime source of research programs for many years.

The 200-inch Reflector.—Closely following the initial successes of the 60-in. and 100-in. reflectors, Hale in 1928 was able to initiate the project that is of incalculable value for nebular research: the building of a 200-in. reflector. The funds were provided by the General Education board of the Rockefeller foundation, on the condition that the telescope be maintained by the California Institute of Technology, Pasadena, and be operated in full co-operation with the Mount Wilson observatory of the Carnegie Institution of Washington. A satisfactory 200-in. mirror of a special Pyrex glass was successfully cast by the Corning Glass Co. at Corning, N.Y., in 1934, and the optical surfacing was done in Pasadena during 1936–42 and 1945–47. Under the direction of I. S. Bowen the telescope with its mirror installed was given thorough optical and mechanical tests, and preliminary astronomical trials, in 1948–49. Hubble had the honour of taking the first nebular photograph on Jan. 26, 1949, with the 200-in. reflector, by this time named the Hale telescope. From about Jan. 1950 this great instrument has been in regular use on the Mount Wilson and Palomar observatories research programs, with discoveries that have already justified the cost, time and resources involved in its realization.

Three results of extraordinary interest for nebular research are: (1) the measurement in 1950 by Humason of a nebular red shift in velocity units of 38,000 mi. per second or nearly one-fifth the velocity of light; (2) the demonstration in 1952 by Baade of the need for revision upwards, by a factor not less than 2, of the extragalactic distance scale; and (3) the identification in 1953 by Baade and Minkowski of several of the brighter optical astronomical radio sources.

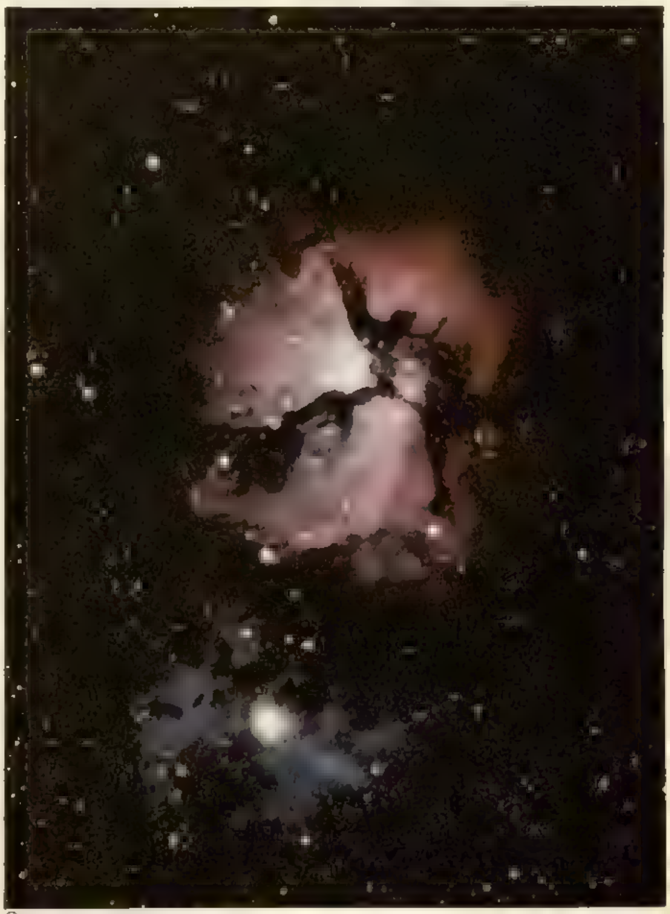
Classification of Nebulae.—As has been explained, the nebulae fall naturally into two groups designated the galactic and the extragalactic. Alternate names for the latter group—by far the largest—are nongalactic, anagalactic, or merely galaxies. Galactic nebulae are found in or near the plane of the Milky Way (the galaxy), while extragalactic nebulae or galaxies are seen, for the most part, outside the Milky Way. The division is not merely one of apparent distribution over the sky, for the two classes of objects differ fundamentally in every important respect, such as distance, intrinsic size and brightness and constitution. In fact, the two categories are so dissimilar that they should logically be separately discussed.

III. THE GALACTIC NEBULAE

These are of two types: (1) diffuse nebulae and (2) planetary nebulae. The first kind includes bright and dark nebulae, but with no clear-cut division, since the two are often found thoroughly mixed together. The second kind has a characteristic appearance, usually a round or a symmetrical structure, with a star near the centre of the nebula.

Diffuse Nebulae

Modern work on interstellar material suggests that diffuse nebulae may be regarded from the following very general point of view. Throughout our own stellar system, of which the fundamental plane is the Milky Way, there is a thin layer of nonluminous



© CALIFORNIA INSTITUTE OF TECHNOLOGY

TRIFID NEBULA (M20, N.G.C. 6514) IN THE SOUTHERN CONSTELLATION OF SAGITTARIUS. A BRIGHT, DIFFUSE NEBULA. IT IS AN EXAMPLE OF THE OBSCURING MATTER LOCALIZED IN STREAKS OR LANES. 48-IN. PHOTOGRAPH

matter. This material, a mixture of atoms, molecules, dust particles and larger masses, is not uniformly distributed, but is relatively concentrated in some regions, and extremely tenuous or absent in others. In some cases denser clouds are situated in front of a bright, starry background. They are then revealed in silhouette, and photographs such as Barnard's record them as dark nebulae.

On the other hand, it often happens that single stars, or groups of stars, lie in the denser parts of the stratum. In this case the stars illuminate the surrounding cloud, much like street lights in a fog, and bright nebulae may be seen or photographed by the light coming from the particles composing the cloud. Mixed bright and dark nebulae occur in circumstances where a cloud is so large that the light from the involved stars does not penetrate

to its boundaries, so that a bright nebula appears to be superposed on a larger dark one; or again, the obscuring matter may be localized in streaks or lanes, which are outlined or contrasted against the brighter and less opaque parts of the cloud.

Bright Diffuse Nebulae.—The true character of these objects became known in 1864–68 when William Huggins (1824–1910) examined several of them with his spectroscope and found their light highly concentrated into a few bright radiations, typical of a rarefied gas excited to luminescence. So many more were subsequently found to have a similar spectrum that for nearly half a century it was generally supposed all diffuse nebulae were incandescent gases. In 1912, however, V. M. Slipher of the Lowell observatory announced that the spectrum of the nebulosity around the Pleiades gave an absorption spectrum, which is a continuous, coloured band of light crossed by dark lines. Furthermore, the nebular spectrum was like that of the stars imbedded in the nebula.

LAGOON NEBULA (M8, N.G.C. 6526) IN THE SOUTHERN CONSTELLATION OF SAGITTARIUS. THIS BRIGHT, DIFFUSE NEBULA IS SO LARGE THAT LIGHT FROM THE INVOLVED STARS DOES NOT PENETRATE ITS BOUNDARIES AND THE NEBULA ITSELF APPEARS TO BE SUPERPOSED ON A LARGER, DARKER ONE. 200-IN. PHOTOGRAPH

These results, which were later obtained for a number of other diffuse nebulae, provided evidence for the view that some nebulae shine by scattered or reflected light directly received from the stars, rather than by emitted light indirectly excited in the nebula by ultraviolet radiation from the stars. The latter mechanism was thoroughly analyzed by I. S. Bowen in 1927, and it is of great astrophysical importance (see *The Gaseous Spectrum of the Nebulae*, below). Before Bowen explained the origin of the nebular emission spectrum, however, Hubble in a pioneering investigation of diffuse nebulae published in 1922 discovered one of the most significant properties of these objects: whether a diffuse nebula shines by emitted light (bright-line spectrum) or by reflected or scattered light (absorption spectrum) depends upon the temperature of the star or stars concerned. Although there is some overlapping, in general it is found that stars hotter than about 20,000° C. (spectral type B1 or earlier) can excite an emission spectrum in the gases in the nebula, while cooler stars merely illuminate the nebular particles.

These results by Hubble and by Bowen stimulated an immense amount of research on the gaseous nebulae, the a[illegible]nce beginning about 1930 and continuing in accelerated fashion to the present. Observationally, Hubble's exploratory survey of known nebulae was followed by a large number of more detailed and extensive searches for fainter nebulae and involved stars; on the theoretical side, Bowen's explanation of the nebular gaseou[illegible]ectrum led to a veritable flood of analytical papers dealing [illegible] the physical processes in the nebular gases. Taken togethe[illegible]s work represents a major increase in astronomical knowledg[illegible]ot merely of the interaction between stars and interstellar [illegible]nd dust, but more generally of the structure and evolution o[illegible] Milky Way.

H I and H II Regions.—One of the stronges[illegible]diations from gaseous diffuse nebulae is the hydrogen alpha ([illegible]) line, which occurs in the red part of the spectrum at a wav[illegible]ngth of 6,563 angstroms (Å). This is a fortunate circumstan[illegible]ause red light is less absorbed than blue in the galactic dust cl[illegible] Thus most modern photographic searches for gaseous nebul[illegible]e been made in Hα light, usually with high-speed cameras of [illegible] Schmidt type employing colour filters or objective prisms to [illegible]ate a narrow band of wave lengths around Hα. This proced[illegible]lso markedly reduces the fogging effect of the night sky airgl[illegible] which chiefly limits the search for faint objects.

A notable application of this technique was that carried out by O. Struve and associates in 1937–42 at the Yerkes and McDonald observatories at Lake Geneva, Wis., and Mt. Locke, Tex. With a large and efficient nebular spectrograph of ingenious new design, they found many extremely faint Hα emission regions in the Milky Way. This observational advance was closely related to a theoretical one of high significance for galactic structure. In 1939 and in 1948 B. Strömgren at the Yerkes and Copenhagen observatories worked out and then applied the theory of hydrogen ionization (electron removal) to the case of hot stars imbedded in the galactic stratum of gas and dust. To him we owe the fruitful concept of fairly sharply bounded regions inside of which there is ionized hydrogen, H II, and outside, neutral hydrogen, H I. This theory not only accounted qualitatively for the appearance of many of the nearly circular patterns and broken arcs of gaseous nebulae, but it also gave numerical values for their radii, which depended upon the gas density and the temperatures of the exciting stars. For example, in an interstellar gas of density one atom per cubic centimetre, a very hot (30,000° C.) O-star could produce an H II region about 500 light-years in diameter, but a cooler (10,000° C.) A-star, one of only 1.5 light-years.

The practical value of these "Strömgren spheres" became apparent as other Hα surveys of the Milky Way, in both northern and southern hemispheres, revealed new gaseous nebulae in large numbers, in a great range of sizes, and of spectacular complexity. But this puzzling pattern in general could be resolved into a hierarchy of interlocking, or overlapping, H II regions, each with its responsible one or more hot stars. In this way, important corroborative evidence was obtained of galactic spiral structure, first found in 1951 in another manner by W. W. Morgan of Yerkes observatory. For these H II regions, as shown by W. Baade's work in 1947–50 on the Andromeda nebula, follow fairly faithfully the windings of its spiral arms.

Variable Nebulae.—These are of two kinds: (1) those associated with unusual variable stars, and (2) those observed to form around novae after outburst. The former may be termed irregular, because of their structure and variability in light, while the latter are described as expanding, because their sizes increase with time.

The irregularly variable nebulae comprise a small group of less than a dozen known members. Without exception, they occur in dark regions of the Milky Way and are close to peculiar variable stars. In appearance they are diffusely irregular, like Hind's nebula (N.G.C. 1555) with T Tauri, or fan-shaped like Hubble's (N.G.C. 2261) with R Monocerotis and N.G.C. 6729 with R Coronae Australis, or double-bowed like that with R Aquarii. Although

all these objects have been repeatedly photographed, there is little evidence that their parts have moved, or that their light variations correspond with those of the involved stars. Spectroscopic study of these nebulae and stars has shown that they are fundamentally different from the gaseous H II regions, for the nebular spectra are generally continuous as for reflection nebulae, while the stellar spectra are characteristic of average or dwarf stars. These results, obtained prior to 1945 mainly by V. M. Slipher and C. O. Lampland at the Lowell observatory in Arizona, and by E. Hubble and A. H. Joy at the Mount Wilson observatory in California, directed attention to stars involved in dense clouds of dust and gas in the galaxy. Modern studies of their mutual interaction have provided information that probably bears directly on star formation (see *Dark Nebulae*, below).

Expanding nebulae result from probably the most violent of all celestial phenomena: the novae. These are stars that suddenly release enormous amounts of energy when they reach a critical or unstable state in their evolution. In only a few hours a normal star may flare up until it shines with a power of thousands of suns, if a common nova, or blazes with a brilliance of millions of suns, if a supernova. These are respectively the cosmic counterparts of the terrestrial A- and H-bombs, for they explosively pour out radiation and gases at fantastically high rates. The radiation [illegible] the nova with the speed of light, 186,000 mi. per second, w[illegible]e ejected gases move outward with velocities of a few hundr[illegible] thousands of miles per second. Thus there is a time lapse between discovery of the nova and direct observation of its expanding gaseous nebula, which is known from spectroscopic observations to originate at the time of outburst. Depending on the amount and velocity of the gases, and the distance of the nova, the expanding nebula may not be seen or photographed until months or years after outburst. But when it can be distinguished from the fading star, measurement of the nebula's size provides one of the best estimates of the nova's distance. For the diameter of the nebula (in seconds of arc) divided by the time since outburst gives the angular rate of expansion, whereas the spectroscopic observations, by Doppler's principle, give the linear rate of expansion (in miles per second). Whenever both angular and linear valu[illegible] the same quantity are known for a remote object, a simple calculation gives its distance.

In this way distances ranging from 1,000 to 5,000 light-years have been determined for some of the best-observed common novae. With these distances and certain reasonable assumptions, it has been calculated that the expanding nebulae probably have masses nearly negligible compared to the stars that produced them. Thus the common novae, despite their spectacular performance, are not disastrously affected. They merely blow off some thin, outermost atmospheric layers, which become invisible in the astronomically brief time of less than 100 years.

The Crab Nebula.—Supernovae are so rare that adequate observations of their nebular gases are available for only one of the galaxy's three known supernovae—that of A.D. 1054. Its cloud of expanding gas is the remarkable Crab nebula in Taurus, which is unique in being so long-lived and so large and bright compared to any possible stellar remnant. Studies by Baade and Minkowski in 1942 showed that the nebula consists of two distinct parts. One is a complex filamentary structure, possibly a distorted thin shell, known to be composed of ionized gas, while the other is a diffuse amorphous mass thought to be mainly electrons. Although a central 15th-magnitude star, whose temperature was computed as 500,000° C., was considered as the energy source, this interpretation has been supplanted by a much more interesting one. In 1949 the Crab nebula was found by the Australian radio-astronomers J. G. Bolton, G. J. Stanley and O. B. Slee to be one of the brightest radio sources in the sky, and in 1952–53 its light was discovered to be polarized, by the Russian astronomers M. A. Vashakidze and V. A. Dombrovsky of the Burakan observatory. They followed up a suggestion by the Russian astrophysicist I. S. Shklovsky, who proposed to account for the unique brightness of the nebula in both optical and radio regions as the radiation of electrons accelerated in a magnetic field—like that in a synchrotron. This explanation was given considerable support in a compre-

CRAB NEBULA (M1, N.G.C. 1952) IN THE CONSTELLATION OF TAURUS, A GASEOUS REMNANT OF THE GALACTIC SUPERNOVA OF A.D. 1054. THE NEBULA IS 5,000 LIGHT-YEARS AWAY AND IS EXPANDING AT 700 MI./SEC. IT IS AN INTENSE RADIO SOURCE WITH PART OF ITS LIGHT BEING POLARIZED. PHOTOGRAPHED WITH THE 200-IN. TELESCOPE AT MOUNT PALOMAR OBSERVATORY, CALIF.

hensive investigation published in 1956 by J. H. Oort and T. Walraven, of Leiden University observatory. From analysis of their photoelectric polarization measurements, they concluded that the magnetic field probably lies in the filamentary structure, and that the energies of particles accelerated in it may be high enough to make the Crab nebula a strong source of cosmic rays.

This expectation was realized in 1963 when H. F. Friedman and his colleagues at the U.S. Naval Research laboratory, Washington, D.C., found that the Crab nebula is one of the brightest X-ray sources in the night sky (the sun, of course, being the strongest one in the entire sky). This discovery, which opened up the entirely new field of X-ray astronomy, was made by launching Aerobee rockets beyond the earth's atmosphere to a distance of more than 100 miles. By firing a stabilized rocket at just the right instant and by remarkable split-second timing of their observations, the same group measured the variation in the X-ray source's intensity as the moon occulted the Crab nebula on July 7, 1964. The X-ray intensity did not suddenly disappear but instead gradually declined to zero as the moon's edge passed in front of the nebula. Thus, it was possible to conclude that the source is not stellar but has a diameter of about 1 minute of arc, or a real size of about 1 light-year near the centre of the nebula.

Dark Nebulae.—The Milky Way contains a great number of dark patches or markings, some nearly devoid of stars. A few were first noted by the Herschels, who thought they were holes giving a view into empty space beyond. Although Barnard at first agreed with this idea, his extensive photographic surveys convinced him and others that the dark nebulae are due to nonluminous matter. Their range in apparent size is enormous: from small patches of a

few seconds or minutes of arc, and long lanes of several degrees like those in Ophiuchus and Scorpio, up to the great rift that bifurcates the Milky Way for some 120° from Cygnus to Centaurus.

It might be thought that little could be learned of objects that are discerned by their apparent lack of light, but this natural impression is far from true. Much has been found out about dark nebulae from their effects on the light of stars seen through or within them. For the nonluminous material is composed of dust or smoke particles—a space smog that scatters, dims, reddens and polarizes passing photons of light, as in the familiar phenomenon of sunset in a hazy atmosphere. All these effects are susceptible of measurement, and the results give information on the distances and dimensions of dark nebulae, and, of equal importance, on the particle size, density, shape and orientation.

Max Wolf in the last decade of the 19th century was first to show how star counts around and in a dark nebula could be used to estimate its distance and absorptive power. Outside the nebula the number of stars increases steadily with faintness; inside, at some level of brightness, the number falls below that outside. The magnitude at which the deficiency appears indicates the distance, while the percentage deficiency gives the total absorption. The method is crude because of the great range in real brightness of stars, but by certain statistical refinements A. Pannekoek of Amsterdam showed that it could give reliable relative distances, and, with a count to faint limits, accurate absorptions. Most of the prominent dark nebulae have been investigated by this star-count method, and it has been found that the nearer ones such as those in Aquila and Taurus and the southern Coalsack are only 400 to 500 light-years distant, while the more remote ones like those in Cygnus, Orion and Monoceros are 2,000 to 3,000 light-years away. The total absorptions generally are in the range from 30% to 95%, although there are some dark nebulae that scarcely obscure and others that are nearly opaque.

Cosmic Dust.—The physics of finely divided material has become a subject of major importance in astronomy because of its bearing on distance estimates, and on theories of star formation and evolution. Obviously, if the intensity of starlight decreases faster than inversely as the square of the distance, as would happen for light passing through obscuring matter, then distances derived from apparent brightness would be too large. It is likewise plain that the most promising place to seek an understanding of stellar origin and early development probably is in a dark nebula, where conditions are favourable for formation of stars by condensation, contraction and accretion processes in the clouds of cosmic dust particles. In both cases, it is vital to have as much knowledge as possible of the physical properties, chemical composition and environmental conditions of this interstellar matter.

Pioneering investigators of the properties of small cosmic grains were H. von Seeliger (1849–1924) of Munich, Ger., and H. N. Russell (1877–1957) of Princeton, N.J. As the result of some work on the swarms of meteorites that form Saturn's rings, Seeliger in 1901 made a theoretical study of the reflection of light from small bodies, and his formulation of the problem strongly influenced much later work on reflection nebulae. Russell, however, in 1922 worked out a theory of submicroscopic particles for which reflection was small compared to scattering or absorption of light. He obtained formulas that gave absorption as a function of particle size, and concluded that dimming was most pronounced for a size about 1/150,000 in., or one-third the wave length of visual light. This theory was considerably extended during 1930–35 by C. Schalén of Uppsala, Swed., who included more specific particle properties in the equations. From the colours and spectra of stars involved in dark nebulae, he inferred that the chemical composition is mainly metallic, with compounds of iron, zinc and copper. Studies of bright reflection nebulae, on the other hand, notably in 1935–40 by O. Struve, J. L. Greenstein and L. G. Henyey of the Yerkes and McDonald observatories, tended to support the hypothesis of a nonmetallic make-up, with icelike compounds of the much more abundant elements hydrogen, oxygen, carbon and nitrogen.

Although there was, and still is, some uncertainty regarding the principal chemical constituents, evidence has steadily accumulated that the mixture of particle sizes is much the same throughout the galaxy. This is an extremely important result for nearly all astronomical researches involving distances beyond the range of direct survey, or trigonometric, methods. The reasons for the significance of this result, and how it was obtained, deserve to be detailed.

Space Reddening of Starlight.—Nearly everyone knows that the sun seems redder near the horizon than overhead, and that the sky around it is blue at normal altitudes. Both effects are due to atmospheric particles that absorb and scatter blue light much more than red. The process is known as Rayleigh scattering, after Lord Rayleigh (1842–1919), who found that the atmospheric absorption varied inversely as the fourth power of the wave length. For example, since deep red light has twice the wave length of deep blue, it is absorbed only $(\frac{1}{2})^4 = \frac{1}{16}$ as much, and objects observed through long atmospheric paths appear reddened by this selective absorption. Moreover, Rayleigh also showed that this particular absorption law is characteristic of particles mainly of dust size, or somewhat less than the wave length of light. Thus the particle mixture is more typical of the chemical composition than of contaminating larger-size dust particles, and it may be considered the same throughout the earth's atmosphere.

RING NEBULA (M57, N.G.C. 6720) IN THE NORTHERN CONSTELLATION OF LYRA, CONSISTING MAINLY OF GASES THROWN OFF BY THE STAR IN THE CENTRE. 200-IN. PHOTOGRAPH

This wave length-selective effect on light that has passed through a nontransparent medium is the means by which astronomers have been able to determine a general interstellar absorption law, to estimate the sizes and kinds of particles, and to correct distances of obscured objects. For example, particle sizes of dust dimensions are estimated from colour observations of reflection nebulae, which are not nearly so blue relative to their illuminating

stars as the daylight sky is to the sun; the elements composing the particles are inferred from much modern work on their abundances in stars and nebulae. To correct a distance of an obscured object, it is necessary to know the total absorption, which can be found from the selective if the absorption ratio = total/selective is known. To determine this ratio and to find out whether it is essentially the same throughout the galaxy, colour observations for a large number of objects and for a long range of wave lengths are required.

The most comprehensive series of programs that provided many of the basic data on space reddening and absorption are those carried out from about 1930–50 by J. Stebbins, C. M. Huffer and A. E. Whitford, of the Washburn observatory, Madison, Wis. By developing and applying photoelectric techniques of precision and of great sensitivity, they first determined accurate colours for more than 1,300 distant high-luminosity O- and B-stars and for most of the globular star clusters. Next, for limited lists of the brighter stars, they obtained six-colour measurements ranging from the ultraviolet to the infrared. Finally, in 1947 Whitford extended the selective absorption curve to the extreme astronomical infrared at 21,000 Å, and showed that a good approximation is a law giving the absorption as the reciprocal of the wave length. Although this law had already been anticipated by previous work on reflection nebulae, and from spectrophotometry of stars in dark nebulae, it was Whitford's far-infrared work that established its validity over the entire astronomical optical spectrum. This inverse wave length law provided the basis for confident calculations of the ratio of total to selective absorption, while the six-colour observations of widely distributed stars gave assurance that it was valid in many Milky Way regions. Since a few apparent exceptions have not stood the test of time, as additional and more precise data were obtained, it may be said that the discolouring dust of space possesses a remarkable uniformity of particle-size distribution, and probably of chemical composition.

Interstellar Polarization.—A significantly new property of the particles composing dark nebulae was discovered in 1949 by J. S. Hall of the U.S. Naval observatory at Washington, D.C., and W. A. Hiltner of the Yerkes and McDonald observatories. They found by precise photoelectric measurements that the light of highly space-reddened stars is polarized. This result means that the interstellar particles are so shaped and oriented in space that they cause passing light waves to vibrate in a preferential plane. By 1956 polarization observations had been made for hundreds of stars of many kinds, in the northern Milky Way principally by Hiltner and by Hall with A. H. Mikesell, in the southern by Elske van P. Smith of the Harvard College observatory. This work showed that: (1) the strongest polarization occurs only for highly reddened stars whose light has been strongly absorbed; (2) the orientation of polarization planes is often closely the same for fairly large regions, of the order of several hundred to 1,000 light-years; (3) there is an over-all strong tendency, along nearly the entire Milky Way, for alignment parallel to the galactic plane. Interpretation of these results indicates, first, that the particles probably are elongated, some four to five times longer than wide, with their major axes generally at right angles to the Milky Way plane, and second, that there is some large-scale mechanism, possibly of galactic dimensions, producing this long-axis alignment. The various explanatory theories of the phenomenon differ chiefly in the chemical composition assumed for the particles. If these are nearly nonconducting or dielectric, hypotheses involving spinning spicules and streaming gases have been advanced; if mainly metallic, a magnetic field. Although the mechanism of alignment cannot be considered uniquely identified, there is increasing evidence, such as the Crab nebula polarization, magnetism in stellar atmospheres and high-energy cosmic rays, that magnetic fields in the galaxy may be important elements in its structure.

Star Formation.—The relationship of nebulae to stellar origins has long been one of astronomy's prime problems, dating from the earliest visual observations of associated nebulae and stars. Little progress beyond philosophical speculation was possible, however, until a great deal of data on distances, dimensions, real brightnesses (luminosities), motions, masses and radiating properties became available for both stars and nebulae. These data demonstrated that the stars of highest luminosity are generally found associated with nebulae both bright and dark, that they radiate energy at such spendthrift rates they can last only a few million years and that their motions in space average among the slowest in the galaxy. Such facts point with more than strong suspicion to a nebular origin for these stars; otherwise their association would not be so close. For the age of the galaxy is reckoned a thousand times greater, and there has been sufficient time for these stars to have moved from nebulae and to dim to comparative obscurity on the cosmic scene.

While this concept seems satisfactory for supergiant stars, they represent but a small part of the galactic population. To be applicable in general, a theory of star formation needs to account for the great bulk of average-type stars like the sun, whose hydrogen mass and energy output can sustain it for several thousand million years. Since many nebulae contain clusters of stars of a wide range of brightness, it seemed reasonable to look closer at some of the fainter ones, and particularly at those whose irregular light variations seemed unique for stars in dark nebulae. From extensive studies of groupings of these fainter nebular variables, the Russian astronomers V. Ambartsumian and P. Kholopov concluded in 1950 they are young stars of unstable behaviour, and termed them T-associations, after the prototype variable T Tauri, the illuminating star of Hind's variable nebula (N.G.C. 1555). In 1945 A. H. Joy of the Mount Wilson observatory reported spectroscopic observations for a number of T Tauri variables that led to their recognition as a distinctive class of emission-line objects found only in dark nebulae. Subsequent surveys to much fainter magnitudes, especially by G. Haro at the Tonantzintla observatory, Mex., and by G. H. Herbig at the Lick observatory, resulted in the discovery by 1950 of hundreds of generally similar stars, without exception in dark nebulae. By 1952 Herbig's detailed studies of the emission-line objects, which comprise only a portion of the variables, revealed for these stars two significant facts that are consistent with the hypothesis of recent formation. First, these stars appear to be rotating abnormally fast for their size and mass; second, they are abnormally bright in blue and ultraviolet light for their temperatures. Both these properties have been predicted in theories of star formation from cosmic dust clouds: as residual rotation from turbulent motions, and as excess radiation from a contracting nebula-star interaction.

Radio Observations of Dark Nebulae.—The development of radio astronomy after World War II provided a powerful new technique for the study of dark nebulae, for two reasons. First, radio waves pass through dense dust clouds that practically blot out ordinary light. Second, the relationship between the dust and involved hydrogen gas may be found as the result of a brilliant prediction in 1944 by the young Dutch astronomer H. C. van de Hulst of the Leiden observatory. He pointed out the possibility of observing radio radiation of 21 cm. wave length from neutral hydrogen, or H I, and it was first detected in the galaxy in 1951 by H. I. Ewen and E. M. Purcell, Harvard university physicists. This discovery, potentially comparable in its consequences with the invention of the telescope, has made possible detailed astrophysical investigations of some of the larger gas-dust complexes in Perseus, Taurus, Orion and Ophiuchus, notably by B. J. Bok and his younger colleagues A. E. Lilley, D. S. Heeschen and T. K. Menon. Working with the 24-ft. radio telescope at the Agassiz station of Harvard College observatory, they reported results in 1954–56 relating to the relative distributions of dust and neutral hydrogen gas, the density ratio of gas/dust and total masses. Over large areas the H I gas emission is prevalent wherever the optical obscuration by dust is evident, but the smaller darkest nebulae are not necessarily the best radio emitters—the dust is apparently more locally concentrated than neutral hydrogen gas. In the Orion-Taurus complex the gas/dust density ratio in the mean is 100, but with a big range from 35 to 250. The average value would indicate, for an estimated total H I mass of 21,000 suns, that all the dust amounts to only about 200 solar masses. These figures, however, involve a number of simplifying assumptions

that are normally unavoidable in a new field. For example, the H I gas/dust density ratio could be appreciably reduced if evidence for molecular hydrogen H_2, or for hydrides like OH, NH or CH were found by improved microwave techniques and larger radio telescopes.

Planetary Nebulae

These are so named because their appearance in a telescope resembles that of planets, for they show disks with definite edges. But unlike the planets, these nebulae show no appreciable motion among the stars, since they are generally more distant than the stars seen in the same field. Compared to diffuse gaseous nebulae, planetaries are apparently and actually much smaller, and they ordinarily have a distinguishing bright-line spectrum.

Numbers and Distribution.—Planetary nebulae as a class are relatively scarce and unique in the galaxy. Only about 130 were known prior to 1940, but prismatic and Schmidt camera surveys by R. Minkowski, G. O. Abell and A. G. Wilson at Mount Wilson and Palomar observatories, by G. Haro at Tonantzintla, Mex., and by K. G. Henize at Bloemfontein, S.Af., by 1956 had increased the number known to nearly 600. Many of these later discoveries appear starlike except on photographs taken with the largest telescopes, and a large majority are in heavily obscured regions. For these reasons there are probably many more undiscovered planetaries, and the galactic total has been estimated as high as 10,000, a small number compared to the stellar population of thousands of millions. Although some planetaries are found all along the Milky Way, but with much less concentration than the stars and gaseous diffuse nebulae, there is a marked grouping of many of the faintest ones in the Sagittarius-Scorpio region, as is the case for the globular star clusters. This distribution means that the planetaries as a system cluster around the centre of the galaxy, at distances ranging up to 30,000 light-years.

Apparent Size and Structure.—In apparent size planetary nebulae range from the large Helical nebula in Aquarius, N.G.C. 7293, which is about half the diameter of the moon, down to objects of a few seconds of arc, so small they can hardly be picked out among stars, unless their spectra are available. In nearly all planetaries that are sufficiently large and bright, a central blue-white star can be found. The few exceptions are more apparent than real, because these central stars are among the hottest celestial sources. They have temperatures in the range from 50,000° to 150,000° C. so that most of the energy is radiated in the far ultraviolet where it is not only invisible but also blocked off by the earth's atmosphere. The nebular gases, however, have a much lower temperature, of the order of 10,000° C. Thus the nebula may be considerably brighter to the eye or on a photograph than the central star.

When planetaries are examined visually or on photographs taken with average-size telescopes, they tend to show a regular structure, which has encouraged classification and interpretation according to simple geometrical forms. The most common of these are shells, rings, spirals and helices. H. D. Curtis (1872–1942) of the Lick observatory pioneered in this approach with the 36-in. Crossley reflector, and found in 1918 that oblate spheroidal or truncated shells, thinner at the equator than at the poles, accounted satisfactorily for the regular appearance of many planetaries. For the brighter ones in the southern hemisphere, A. D. Thackeray and D. S. Evans in 1950 reported a similar survey based on plates taken with the 74-in. reflector of the Radcliffe observatory, Pretoria, S.Af. They described the observed forms in terms of a simple disk and ring, with central symmetry about two perpendicular axes; but for about 30% of the objects they gave the classification as irregular.

These idealized geometrical models, although useful in the exploratory or survey stages, are found to be inadequate when confronted with the most recent material obtained with the largest telescopes and improved techniques of photography and spectroscopy. R. Minkowski's photographs taken since 1950 with the 200-in. Hale telescope reveal in most cases a complex arrangement of filaments, knots, streamers and arcs that are difficult to fit into simple geometrical figures. These difficulties are due to at least two properties of the nebular gases. First, the ions (atoms minus electrons) of different gases are distributed differently, as shown by colour-filter photographs or slitless spectrograms that isolate individual emission lines of the various elements. Second, when the emission radiations are studied with slit-spectroscopic methods, internal motions of different amounts are found for different ions.

Internal Motions.—These were first found convincingly in 1916–18 by W. W. Campbell (1862–1938) and J. H. Moore (1878–1949) of the Lick observatory. They observed that the chief nebular lines of oxygen are not strictly single (monochromatic) in a number of planetaries. The lines appeared broadened or split into two components, which by Doppler's principle points to different velocities in the line of sight. The measured differences ranged from 10 to 60 mi. per second among the planetaries studied, and were considered due to rotation of the nebulae. Later developments showed, however, that the effects were produced by gases that move generally outward from the central stars, the expansion velocities being half the observed velocity differences. These observations were far ahead of their time and remained unapproached in accuracy and completeness for nearly 30 years.

In 1946 O. C. Wilson of the Mount Wilson and Palomar observatories began a systematic program of spectroscopic investigation with much more powerful equipment. First with the 100-in. and after 1953 with the 200-in., he used the large-scale slit spectrographs at the coudé foci of these reflectors to obtain greatly dispersed spectra of the brighter planetaries. By 1950 he had found that no unique expansion velocity could be assigned to the same nebula, but that instead there are systematic motions related to the type of ion: those most highly excited (produced with highest energy) show smaller velocities than those of low excitation, except for hydrogen. Despite these additional complexities, Wilson found a model that showed promising agreement with the observations. These could be accounted for if it were assumed that the expansion velocity of any ion is the same as the hydrogen-helium velocity in the region where the ion is produced. To test this and other models, it was desirable to obtain radial velocities for a large number of points in each nebula. In 1953 the 200-in. coudé spectrograph was therefore provided with a multislit. This device consists of a series of closely spaced slits by which radial velocities for as many as 31 sections of a nebula may be obtained from a single exposure. In preliminary reports to 1956, observations made this way strongly support the view that several of the regular planetaries are ellipsoidal because the expansion velocity varies in a regular fashion from the centre. It seems that the constituent gases are arranged in space according to their velocities, the fastest ones being found farthest out.

Motions in the Galaxy.—The emission-line spectrum of planetaries has made possible the fairly accurate determination of radial velocities for even the faintest ones, and to Campbell and Moore is likewise due the first extensive list published in 1918. These data were thoroughly analyzed in 1937 by L. Berman of the Lick observatory, who concluded that the planetaries participate in the general rotation of the galaxy, and that those having the highest velocities are farthest away, as expected from the simple theory of circular motion. But the location of so many of the newly discovered fainter planetaries in the region of the galactic centre suggested an alternative interpretation of the largest velocities as motions in highly eccentric orbits. These could reasonably be inferred if additional radial velocities of a large and more random character were found for the numerous faint planetaries around the galactic centre. In 1953 a co-operative program to provide these new velocity data was undertaken at the Lick and Mount Wilson-Palomar observatories. From a preliminary report given in 1955, it seems likely that these new velocities may indicate less galactic rotation among the planetaries than formerly found, and a larger velocity dispersion in the direction of the galactic centre. Since these circumstances are similar to those for the globular star clusters, it is probable that they and the planetary nebulae belong to the same population group: Baade's type II.

Distances, Dimensions and Densities.—Planetary nebulae are so far from the sun that direct trigonometric distance deter-

minations are useless, while statistical treatments of transverse or proper motions are unreliable, because the field comparison stars used in the measurements are at comparable distances. In an effort to minimize these difficulties, Berman derived a set of internally consistent distances from proper motions, angular diameters and galactic rotation theory applied to the radial velocities. In this way he obtained a scale of distances ranging from 3,000 to more than 30,000 light-years, but the values for individual nebulae are uncertain in some cases by factors of 2 or 3, because of the large dispersions in velocity, luminosity and diameter, and the irregular galactic absorption.

Berman's distance scale appears to be statistically of the right order, however, because of two independent but indirect checks on it. In 1950 Minkowski discussed the angular diameters of planetaries, with special reference to the more than 100 newly found ones in the direction to the galactic centre. By assuming them to be at the average distance of 30,000 light-years, he obtained the distribution of linear diameters, and found agreement with the corresponding one obtained from Berman's distance scale. Then in 1955 Baade discovered several of the brightest planetaries in the Andromeda nebula, on plates taken with the 200-in. Hale telescope. These planetary nebulae in the spiral have apparent magnitudes of 22, which is very nearly the brightness to be expected if the galactic planetaries, with luminosities based on Berman's distance scale, were viewed from a distance of 2,000,000 light-years.

The average linear diameter of the planetaries discussed by Minkowski is 30,000 astronomical units (1 a.u.=93,000,000 mi.), but this figure fails to tell the whole story of sizes of planetary nebulae. It does not include, for example, the faint outer extensions that are often observed in the nearer and brighter ones, which may reach 200,000 a.u. in size. Also, as Minkowski points out, the observed sizes represent only the ionized part of the nebular mass, and the neutral part may be much larger, as found for the diffuse gaseous nebulae in radio observations. On the other hand, there are a number of semistellar, dense planetary

nebulae, whose small diameters and spectroscopic characteristics suggest comparison with peculiar stars having extended atmospheres. Thus there is in reality a great range among planetary diameters, and size may be meaningless unless it is specified in terms of a particular density, element or degree of ionization.

The densities and masses of planetary nebulae can be fairly well estimated from theories of the physical processes in gaseous nebulae, since some of the most important atomic quantities are obtainable independently of the distance. For example, the density and temperature of electrons in the nebular gas may be deduced entirely from spectroscopic observations and astrophysical theory. In fact, the procedure may be reversed and, with the addition of absolute surface brightness measurements, used to estimate distances, as first indicated by D. H. Menzel in 1931 before there was a generally accepted distance scale. For some of the best-observed planetaries, moreover, the astrophysical results derived with and without distances are in substantial agreement. Thus there is reasonable reliability for the following estimates: density of a typical bright nebula: 1,000 to 10,000 ions per cubic centimetre; mass: one-tenth to one-fifth that of the sun. In the faint outermost parts the density may be only 100 atoms per cubic centimetre. This value has been brought down to earth by L. H. Aller of the University of Michigan observatory, who obtained and critically analyzed (in 1956) much of the best material in the field, by the statement that the density represents "a tenuity comparable to that of a few tablespoonfuls of air expanded to the size of Pikes Peak."

Origin and Evolution.—Planetary nebulae are so rare on the cosmic scene—less than one per 10,000,000,000 stars—that on the grand scale their evolution cannot be regarded as an important stage in general stellar evolution. Instead, planetaries serve best to draw attention to a particular process in stellar atmospheres: the ejection of material from the hottest stars. Since this phenomenon has been repeatedly observed in modern novae, it was natural to postulate that perhaps planetaries resulted from and represent the remnants of prehistoric nova outbursts. Apparent support for this view came from M. L. Humason's report in 1938 that 16 faint "old" novae are hot, blue stars like the nuclei of planetaries. This analogy, however, breaks down completely when subjected to quantitative analysis. For the gas masses, velocities of expansion and lifetimes of the nebular shells are of different orders of magnitude for novae and planetaries. Despite the many assumptions involved, reasonably computed values for a typical nova outburst are: 1/100,000 solar mass for the thrown-off gas, 1,000 mi. per second for the velocity of ejection and 50 to 100 years for the visible lifetime of the expanding nebula; corresponding figures for a representative planetary are 1/10 sun, 10 mi. per second and 10,000 years. Thus a planetary nebula requires for its origin and development a prolonged ejection process, one that may operate for a substantial fraction of the nebular lifetime. Although both novae and planetaries are transient phenomena on the general evolutionary scale of millions and billions of years for stars, the relative ages of nova and planetary nebular shells are those of an explosion and a slow burn.

The Gaseous Spectrum of the Nebulae.—The spectra of all gaseous nebulae, diffuse and planetary, are very similar in appearance, the differences consisting chiefly in the relative intensities of the bright lines. The lines in the spectra are sharp, a fact indicating a gas of low density; those of hydrogen are prominent and those of helium are usually present. But for more than 60 years following 1864, when William Huggins first observed the spectrum of a nebula, there were several lines (a wide pair in the green at 5,007 and 4,959 Å, and a close pair in the ultraviolet at 3,726 and 3,729 Å), among the strongest in the spectrum, which remained unidentified. Their origin was one of the most puzzling mysteries in astronomy, and for lack of a better name, they were attributed to a hypothetical element called "nebulium," although it was generally realized, because of advances in chemistry and physics that left no place in the table of known elements for foreign ones, the occurrence of the strange lines probably was due to some familiar element existing under conditions peculiar to the nebulae. That this explanation is the correct one was established in 1927 by I. S. Bowen. He showed on the basis of laboratory work and quantum theory calculations that the chief nebular lines are due to singly and doubly ionized oxygen atoms, which radiate light under conditions of extremely low density and long light paths—a combination unmatched on the earth.

Forbidden and Permitted Lines.—To understand why certain lines occur in the nebulae and not in terrestrial sources, it is necessary to mention a few of the fundamental principles of modern atomic theory. In this concept, atoms exist in certain definite energy states, depending on their environment. The energy states may be likened to orbits in which electrons move about the nucleus, and when an electron jumps from one orbit to another, energy is absorbed, or emitted, depending on whether the jump is from an inner to an outer orbit, or the other way around. The electrons, however, do not remain in the different kinds of orbits for equal times, and it is this property of the atom, together with its environment, which is responsible for the characteristic nebular radiations. The latter represent jumps to orbits in which electrons can move for hours and days, whereas radiations observed in terrestrial light sources correspond to transitions between orbits in which electrons remain for only 1/100,000,000 of a second. Spectral rays from long-lived orbits are called "forbidden" lines, those from the short-lived orbits "permitted" lines, and the reason only the latter are obtained in the laboratory is that collisions between atoms, even with the lowest obtainable densities, are so numerous (millions per second) that electrons are almost always knocked from the long-lived orbits before they have a chance to jump to an inner orbit, with the resultant emission of a forbidden line. In the nebulae, however, the extremely low densities and long light paths allow sufficient electrons to accumulate in the long-lived orbits (called "metastable states") to yield intense forbidden lines.

Physical Processes and Sources of Energy.—In addition to demonstrating the existence of an almost perfect vacuum in gaseous nebulae, the forbidden lines due to ionized atoms indicate the presence in planetaries of a very high-temperature source of energy. Evidence for this conclusion is provided by two apparently unrelated features of the nebular spectrum: (1) the size of a nebula is different in different radiations, and (2) only certain of the permitted lines of neutral oxygen and nitrogen are observed. The first of these properties, originally noted in 1908 by M. Wolf, and later (1918) extensively studied by W. H. Wright in his classically thorough investigation of the spectra of the gaseous nebulae, shows that the smallest nebular diameters correspond to the most highly ionized atoms, and the largest to the least, in just the way to be expected from Bowen's high-temperature theory of the structure of planetary nebulae. The second feature was likewise explained by Bowen as the result of an intense concentration of energy in the far ultraviolet, characteristic of a high-temperature source, which selectively excites the observed lines by a fluorescent mechanism. That the central stars of planetary nebulae are in reality among the hottest objects known was also established by Wright's observations of the spectra of planetary nuclei. Subsequent theoretical investigations by H. Zanstra, A. S. Eddington (1882–1944) and D. H. Menzel have fully substantiated Wright's earlier deductions from observations, and Bowen's conclusions from identification of the chief lines, that the dominating physical conditions in gaseous nebulae are extremes of low density in the nebulae and of high temperature in the central stars, which are the ultimate sources of all nebular radiations.

Abundances of the Nebular Gases.—Following his explanation of the origin of the nebular lines, and the mechanism of their production, Bowen in 1934 concluded that the gaseous nebulae, like most astronomical bodies, are largely made up of hydrogen, with helium the next most abundant element. Further information on their chemical composition was obtained in 1939 by Bowen and A. B. Wyse (1909–42) at the Lick observatory. By using an especially powerful spectrograph in combination with an "image slicer" (invented by Bowen to overcome certain observational difficulties), and exposures of 12 to 20 hours, they were able to record in two planetary nebulae a number of faint radiations due to the

on the sun, led to the conclusion that the abundance of many elements in the nebulae and sun are not significantly different. Wyse in 1941–42 extended the program to include ten additional planetary nebulae and the Orion nebula, and deduced that the chemical compositions in both types of nebulae are similar to those of the sun.

This finding of a common chemical composition, especially for objects so apparently dissimilar as gaseous nebulae and an ordinary star, stimulated many modern researches on the cosmical abundances of the elements. Gaseous nebulae, and particularly planetary nebulae, continued to play prominent parts in both theoretical and observational developments. For the astrophysics of such low-density high-temperature sources are more amenable to mathematical treatment, while planetaries have the highest surface brightnesses. Thus the theory used by Bowen and Wyse was greatly extended during 1937–45 at Harvard College observatory by Menzel and his colleagues J. G. Baker and L. H. Aller; and, after World War II, further investigations of several of the brightest planetaries were carried out at the Mount Wilson and Palomar observatories by Aller, Bowen and Minkowski. In 1952–54 they used the powerful spectrographic equipment of the 100-in. and 200-in. reflectors to obtain much new material on the wave lengths, intensities and identifications of several hundred of the fainter radiations previously only suspected or unrecorded. From these spectrochemical analyses, Aller and Minkowski in 1956 found that the abundances of elements in seven planetary nebulae (1) do not differ significantly, and (2) the average composition is essentially the same as in stars (*see* table, adapted from compilations by L. H. Aller, University of Michigan observatory, Ann Arbor, Mich.).

IV. THE EXTRAGALACTIC NEBULAE

The extragalactic nebulae are found over the entire sky, except within the close confines of the Milky Way, or galaxy, where the cloudy stratum of interstellar matter blots out the light from more distant objects. This surface distribution hints of distances beyond the galaxy—extragalactic—and it is a clue reinforced by the observed ranges in size, brightness and numbers. These attributes all strongly support the suggestion of a perspective progression of objects. For extragalactic nebulae are found smaller, fainter and more numerous, as the more powerful telescopes reach ever farther into space. In diameter and brightness they range from the great 10°, 1st-magnitude Large Magellanic Cloud to the small 1-second-of-arc, 23rd-magnitude specks scarcely distinguishable from stars, even with the large 200-in. Hale telescope. Their number is enormous and depends upon the limiting brightness to which they are counted. Thus some 1,000 are catalogued to the 13th magnitude, and they increase approximately by a factor of 4 for each fainter magnitude: 4,000 to the 14th; 16,000 to the 15th, etc. If this geometric rate of increase were main-

tained to the optical threshold of the 200-in. reflector, the enumerable extragalactic nebulae would total 1,000,000,000. This number, however, has to be corrected downward because of the different quality of light from the faintest extragalactic nebulae. Although the smaller corrected number is not precisely known, it is of the order of hundreds of millions, and this figure represents a population parameter of the universe that challenges the imagination. For each one of these millions of faint flecks of light is a stellar system, or "island universe," composed of myriads of stars. Many also contain interstellar gas and dust, and some are giants in size, population and real brightness comparable to our own galaxy. Since the most numerous extragalactic nebulae are literally vanishingly faint, even the largest telescopes are hard pressed to provide data much above the margin of error. The farthest reaches of the universe are accordingly only sketchily scouted observationally, and there are hosts of unsolved problems and unanswered questions at this dim astronomical horizon. Chief among these is the extragalactic distance scale, which even in the mid-1960s was uncertain by a factor of 2. But it is a real achievement of the largest telescopes that the distances of the faintest extragalactic nebulae may be estimated reliably as to order of magnitude: about 5,000,000,000 light-years.

Classification.—The most generally accepted scheme of classification for the extragalactic nebulae is the one proposed by Hubble in 1926. It is represented schematically in fig. 1. This system arranges in a single homogeneous pattern nearly 98% of the numerous regular nebulae that are sufficiently large and bright to show appreciable structure on photographs taken with telescopes of moderate power; the remaining 2% or 3% that do not readily fall into the system are called irregular nebulae. The basic feature of the classification is, in Hubble's words, "conspicuous evidence of rotational symmetry about dominating, central nuclei."

As may be seen from fig. 1, the regular nebulae begin the sequence as elliptical nebulae, denoted by E. Their forms range from globular to lenticular, with the degree of ellipticity indicated by numerals from 0 to 7, which are obtained from the relation $10(a-b)/a$, where a and b are the major and minor axes, respectively. Statistical analysis of the frequency of occurrence of the different forms shows that there are actually globular or spherical nebulae, and that not all of the apparently round ones can be accounted for as flattened nebulae with polar axes in the line of sight. The analysis shows, however, that the lenticular objects are much more common, and that there is a definite limiting ellipticity with ratio of axes 3 to 1. When the flattening becomes greater, the nebulae no longer appear as smooth, unresolved objects, and, at a certain stage of the sequence, indicated by So, they begin to show structure that in general is of spiral character. Two different spiral forms are found, however, so that the spiral nebulae are separated into two groups: the normal spirals, designated by S, and the barred spirals, symbolized by SB.

Among the regular nebulae large and bright enough to classify, the spirals outnumber the ellipticals by more than 4 to 1, and this fact stresses the importance of deciding which features in spirals are best suited for further subdivision, such as central concentration, relative size of arms and nucleus or number and character of condensations. After an examination of hundreds of nebulae on photographs taken with the Mount Wilson reflectors, Hubble concluded that the most significant characteristic for classifying spirals is the degree of resolution. Depending upon circumstances, the resolution may be only into spiral structure, into clusters or clouds of stars or, at best, into individual stars. To indicate the degree of resolution the letters a, b or c are placed after S or SB; thus, a well-resolved normal spiral would be referred to as Sc, a barred one as SBc.

When the 200-in. Hale telescope, completed in 1948, came into operation, its greater light-gathering and defining power showed so much more detail in the brighter extragalactic nebulae that Hubble initiated a program to refine his classification system, particularly in the transitional So stage between ellipticals and spirals. Although he obtained a number of plates and made numerous notes, his death in 1953 left this work incomplete and unpublished. His younger colleague, Allan Sandage, undertook to finish the job with the result that in 1961 the Carnegie institution of Washington, D.C., was able to issue a memorial volume, the *Hubble Atlas of Galaxies*.

This folio of photographs contains high-quality reproductions of dozens of the best plates taken with the 200-in. reflector, with a systematic discussion of the structural features of ellipticals, spirals and irregulars. It is, in fact, an atlas and gazetteer of most of the larger and nearer systems observable from the northern hemisphere.

Distribution.—As the result of extensive counts of extragalactic nebulae on photographs taken chiefly at the Mount Wilson, Palomar and Lick observatories in the northern hemisphere, and at the Harvard college observatory station in the southern hemisphere, it is known that the distribution is nonrandom over the sky and approximately uniform in depth. This last result, of great theoretical and practical value for cosmological studies, was established chiefly by Hubble's survey that quantitatively elucidated the effects of galactic obscuration, and of several great clusters of nebulae, upon the true distribution.

Counts.—Long before the advent of photography it was generally known from visual observations that the "white" nebulae, now called extragalactic, tended to avoid the Milky Way, and that there was appreciable clustering in high galactic latitudes, especially in Coma and Virgo close to the north pole of the galaxy. With the development of photography, more and ever more nebulae were counted, and the galactic zone of avoidance and the regions of clustering became more precisely defined. A number of early counts, among them those of J. E. Keeler (1899), E. A. Fath (1914) and H. D. Curtis (1918), suggested the general outlines of the distribution and gave hints as to the total number of nebulae within reach of certain telescopes, but the problem of nebular counts was not put on a firm quantitative basis until 1934. In that year Hubble published the results of surveys, made with the Mount Wilson reflectors, in which more than 44,000 nebulae were counted in 1,300 sample regions rather evenly distributed over three-fourths of the sky. For the first time, the counts were calibrated and referred to specified limiting magnitudes. With all the data reduced to standard conditions, it became clear that the numbers of nebulae decreased in a very regular way as the Milky Way was approached. The rate of decrease, in fact, was just that to be expected from a thin obscuring layer in which the absorption is proportional to the light path in the stratum—a familiar analogy is the dimming of stars as they approach the horizon. The zone of avoidance along the galaxy is thus but the effect of looking in the plane of the stratum, where the absorption is a maximum that approaches complete opacity; toward the galactic poles, the absorption is a minimum, with the light reduced by only 20%. The more populous areas, on the other hand, represent a conspicuous tendency for the nebulae to cluster. They occur in pairs, in small to large groups of several to 100 nebulae and in great clusters that include more than 500 members, as in the Coma and Virgo aggregations.

Hubble's classical counts to faint magnitude limits in small sample areas stimulated much interest and work in this field, but these other investigations were necessarily of a different type, as they involved surveys over wider regions to brighter limits, as befitted less powerful equipment than the 60-in. and 100-in. Mount Wilson reflectors. Modern sequels in which astrographs (star cameras) and Schmidt telescopes were used are: (1) the extensive two-hemisphere Harvard surveys carried out from about 1930–50; (2) the Palomar-Schmidt programs begun in 1937; and (3) the Lick comprehensive counts undertaken in 1948.

Harvard Counts.—In 60° diameter zones centred on the equatorial and galactic polar caps, the Harvard counts to the 18th magnitude yielded three important results for what Shapley has called the Inner Metagalaxy, a sphere of diameter 300,000,000 light-years. First, the region of the north equatorial polar cap around Polaris appears to be thinly veiled by galactic obscuring matter, as shown by subnormal counts compared to the surroundings. This result provided independent supporting evidence that some of the International Polar Sequence stars of standard brightness and

(BOTTOM RIGHT) IRREGULAR (IRR) EXTRAGALACTIC NEBULA (N.G.C. 4449). LIKE THE MAGELLANIC CLOUDS, THIS TYPE OF NEBULA SHOWS LITTLE REGULARITY OF STRUCTURE, ALTHOUGH IN MANY CASES THERE APPEAR TO BE INCIPIENT BARS AND SPIRAL ARMS. 200-IN. PHOTOGRAPHS

colour probably are dimmed and reddened, as had previously been suspected from precise photometric work. Second, the survey of the southern equatorial polar cap containing the Magellanic Clouds gave the first clear-cut indication, from wide, continuous-area counts, that extragalactic nebulae may have a higher degree of organization than clustering: arrangement in great, rich clouds extending throughout vast regions of space, of dimensions up to 100,000,000 light-years. Third, comparison of the counts for the galactic polar caps showed a systematic difference between them. In the southern cap the distribution is remarkably smooth over the sky and uniform in depth. But in the northern it is conspicuously irregular, with numerous clusters of both bright and faint nebulae that give an average population in the north nearly twice as large as in the south. This excess is particularly pronounced for the brighter objects, which are found in a broad band running through Ursa Minor and Major, Canes Venatici, Coma, Virgo and Centaurus, to which H. D. Curtis has given the apt name "canopy of galaxies."

Palomar Counts.—The Palomar programs, carried out by F. Zwicky and his collaborators at the California Institute of Technology, Pasadena, used photographs taken with the Palomar observatory Schmidt telescopes: since 1937 with the 18-in. and after 1949 with the 48-in. Special attention was given to the phenomenon of clustering of extragalactic nebulae, particularly as related to the question of the presence of material between nebulae, "intergalactic matter." By 1953 Zwicky had become convinced of the existence of such matter in both the "luminous" and "nonluminous" states. Intergalactic luminous matter was inferred from a variety of faint phenomena newly discovered by the powerful Palomar Schmidt telescopes: (1) large numbers of faint blue stars distant up to 30,000 light-years from the Milky Way plane; (2) some intrinsically very faint and small dwarf nebulae, all within about 2,000,000 light-years of the galaxy; (3) hundreds of streamer-connected double and multiple nebulae out to distances of the order of 200,000,000 to 300,000,000 light-years; (4) exceedingly faint and unresolved luminous patches in clusters and groups of nebulae. Intergalactic dark matter, on the other hand, was inferred from fewer numbers of faint background nebulae counted within foreground clusters, as if the latter contained material that absorbed the light of distant objects. Zwicky has boldly generalized these results as indicating a continuous progression of intergalactic matter ranging from a gas, through dust particles, to individual stars and dwarf stellar systems. But whether this internebular substratum comprises the major portion of the extragalactic population, as advocated by Zwicky, remains more of a question than an answer.

Lick Counts.—Begun in 1948 by C. D. Shane and C. A. Wirtanen, these represent the most comprehensive plan so far undertaken to achieve uniformity and completeness over the sky from the north equatorial pole to a southern declination of 23°. The basic material consists of a set of 1,246 astrograph plates on which nebulae could be counted to a limiting magnitude of nearly 18.5. Each plate was exposed two hours and covers an area of 6° × 6°. With plate-centres 5° apart, an overlapping border at least 1° wide all around each plate provided the means—duplicate counts in a common region—for reduction of the counts to a homogeneous system.

Nebulae were counted in 10-minute-of-arc squares, the numbers summed by square degrees, averaged in groups of four and used to construct "contour maps" of nebular surface density. For practical reasons, the sky was divided into nine approximately equal areas. By 1960 the counting was complete, with the final census totaling about 2,000,000 nebulae. This work, of monumental proportions in concept and effort, provides by far the best basic data for many researches in which a detailed knowledge of the distribution of extragalactic nebulae is important. The published counts delineate, much more exactly than before, the extent and transparency of the obscuring clouds in and around the Milky Way; also, they confirm with a wealth of new data previous indications that clustering of nebulae is not only common but that clusters often are but subsidiary condensations in larger clouds (*see* sections *Clusters* and *Superclusters,* below).

Numbers and Distribution in Depth.—Of equal or greater importance than the delineation of regions of avoidance and of clustering is the conclusion, first reached by Hubble, that the extragalactic nebulae populate space with an approximately constant density as far as telescopes can reach. This result was obtained from counts of nebulae to successively fainter limiting magnitudes. For the brightest objects, it is only necessary to total to each limiting magnitude the number of nebulae whose magnitudes have been individually determined, as for example in the extensive Harvard surveys reported by Shapley. For the faintest objects, on the other hand, it is much simpler to count nebulae to limiting magnitudes determined by exposures of different lengths, or by telescopes of different light-gathering power. This indirect procedure is expedient because the faintest nebulae are overwhelmingly too numerous to estimate their individual brightnesses. With the numbers of nebulae established to increasingly fainter magnitudes, it is relatively easy to test the hypothesis of constant space density. This is done by noting whether the numbers of nebulae counted are proportional to the volumes of space in which they are found. More precisely, a simple calculation shows that the rate of increase is by a factor of four when the limiting brightness decreases by one magnitude. On the basis of all the available material, Hubble found that this condition was satisfied to about the 18th magnitude. At this point the red shifts in the nebular spectra begin to make photographic magnitudes abnormally faint, with the result that the observed number falls below that expected on the basis of a uniform distribution. The following table, obtained from Hubble's counts of faint nebulae, illustrates the total numbers involved:

Apparent photographic magnitude	18	19	20	21	22	23
Uniform distribution, millions	2.3	9.3	37	150	(590)	(2300)
Observed numbers, millions	1.8	5.6	18	57	(180)	(560)

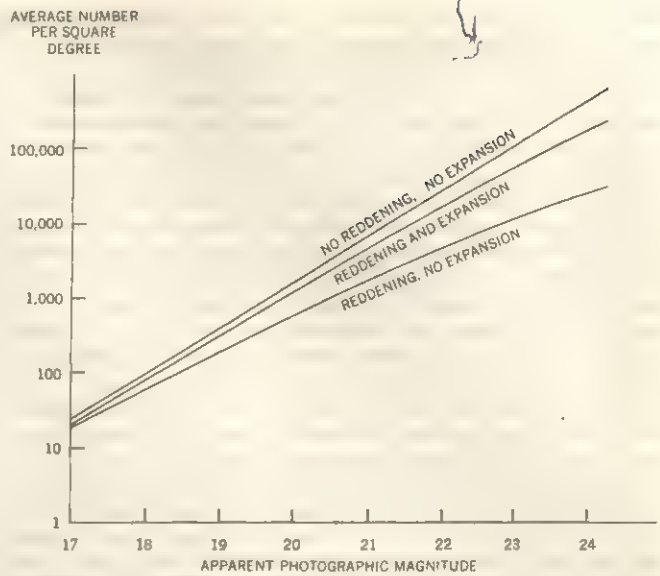
Although the numbers in parentheses represent extrapolations beyond the actual counts, it is evident that the deficiency of the observed to the expected uniform count is by a factor of 3 to 4. In his classical treatment of the subject, Hubble in 1936 used these differences to interpret the nature of the red shift. He concluded that either there is a probable uniform distribution of nebulae in depth, with the red shift not representing recession; *i.e.*, no universal expansion, or, if outward motion is involved, "some vital factors have been neglected in the investigation."

Subsequent developments disclosed these factors, and reopened the entire matter. In the vanguard of progress was the perfection of photoelectric methods of magnitude measurement for faint sources. New observations with this technique, made in 1947–49 by Stebbins and Whitford, left little doubt that the photographic magnitude standards available to Hubble possessed serious systematic errors. With the 100-in. reflector they were able to reach magnitude 18.5, where they found the previous standards too bright by 0.5 magnitude. Extension of the photoelectric measurements to the range of the faintest nebular counts required the use of the 200-in. Hale telescope, and in 1955 W. A. Baum reported the determination of a stellar magnitude of 23.9. However, such observations are difficult and slow, even with the largest telescope, for which Baum estimated two nights of good conditions would be required for an accuracy of 2% at magnitude 23. Nevertheless, by 1955 photoelectric standard magnitudes, in three selected areas and ranging over 10 magnitudes in two colours to magnitude 22 or 23, were reported to have been determined with satisfactory precision and freedom from systematic error. In this way the groundwork was prepared for further counts of the faintest nebulae. But by 1965 no systematic program using the largest-reflector photographs, comparable to Hubble's 1936 reconnaissance, had been undertaken. In 1952, however, J. Neyman and E. L. Scott of the University of California statistical laboratory, initiated a broad, theoretical program using statistical methods to predict the numbers of faint nebulae expected to different magnitude limits. Their formulation included a wide variety of models, with and without clustering, red shift or expansion. As a result of this work, there was available by 1960 a theoretical framework especially adapted to the comparison of forthcoming nebular counts with various theories of the distribution in depth. An example of results from the calculations is given in fig. 2. This shows that the surface density of extragalactic nebulae near the faintest magnitude limits attainable with the largest reflectors is astonishingly high—of the order of 10,000 nebulae per square degree. In the higher galactic latitudes there will thus be more nebulae than stars, as predicted by Hubble in 1934, and verified by him with the 200-in. reflector in 1949.

The observed distributions of the faintest extragalactic nebulae and stars therefore present complementary aspects of the sky, related to our position in the galaxy. In its plane the rich star cloud provides the limiting background of threshold sources, while at its poles the piled-up population of faintest nebulae produces the distant and hazy horizon. There, strangely as at sunset, these extragalactic beacons are aglow with a ruddy hue—the universe's "stop signal," the red shift.

Clusters.—Extensive surveys first by astrographs and later by Schmidt cameras have shown that clustering of extragalactic nebulae is by far the rule rather than the exception. The most modern program, which is F. Zwicky's with the Palomar 48-in. Schmidt telescope, indicates that these clusters are to be counted in the thousands. He reported in 1952 that on one plate covering about 40 square degrees in Coronae Borealis nearly 100 clusters could be identified. So many clusters suggests that they, instead of individual nebulae, may be the fundamental building blocks of the universe. If this is the case, then clusters of nebulae promise to provide significant information on the structure of the universe, in addition to having served as stepping stones for Hubble's extragalactic distance scale.

On the observational side, Zwicky's extensive cluster material obtained with the Palomar Schmidt telescopes from about 1937–56, led him to a number of conclusions regarding clusters of nebulae. In 1956 he summarized these results, some of which are



BY COURTESY OF THE UNIVERSITY OF CALIFORNIA PRESS

FIG. 2.—NUMBERS OF EXTRAGALACTIC NEBULAE TO VARIOUS LIMITING MAGNITUDES, FOR DIFFERENT ASSUMPTIONS AFFECTING THE DISTRIBUTION IN DEPTH. NUMERICAL DATA FROM HUBBLE'S OBSERVATIONS

the following: (1) clusters exist as open clouds, medium compact swarms and spherically symmetrical condensations, with isolated nebulae clearly in the minority; (2) the richest clusters may have (a) as many as 10,000 members within the range from the brightest to those seven magnitudes fainter, and (b) an internal velocity dispersion of 1,500 mi. per second; (3) both luminous and dark clouds of intergalactic matter have been found concentrated toward the centres of large clusters; (4) clusters appear to be distributed uniformly and randomly in a nonexpanding universe, as inferred from studies of brightnesses and diameters of nearly 1,000 rich clusters; (5) there is no systematic clustering of clusters. Some of these and other findings by Zwicky are subject to confirmation by further, independent observations, or are susceptible of alternate interpretations. Nevertheless, Zwicky and his collaborators have shown that the Palomar Schmidt photographs are in a class by themselves as regards the recording of the faintest nebulous sources in the extragalactic regions.

On the theoretical side, J. Neyman and E. L. Scott in a series of papers beginning in 1952 assumed that all extragalactic nebulae are members of clusters. Using mathematical statistical methods, they sought to formulate the problem of spatial distribution of nebulae in such a way that as many as possible of the basic assumptions and related postulates could be tested separately by nebular counts. They found it convenient to classify the postulates into three groups: (1) those concerned with the distribution of nebulae in space; (2) those that relate events in space to what may be seen on a photograph; and (3) those connected with the unavoidable errors of counting. For the observational tests of the deductions from the theory, they used C. D. Shane's and C. A. Wirtanen's comprehensive counts of nebulae on the Lick 20-in. astrograph plates. In 1954 Neyman and Scott reached the conclusion that a hypothesis of simple clustering could represent the observations in some, but not all, respects. In particular, they found that frequencies of counts in 1° squares agreed closely with theoretical expectations, although for an unsatisfactorily large range of the observational parameters. For the same parameters, however, frequencies of counts in 10′ squares could not be reconciled with those in 1° squares. The discrepancy was in the sense of the observations showing an excessive number of clusters with small angular diameters, as compared with theoretical prediction. They suggested that the most promising modifications of the model of simple clustering in order to reach agreement with observations, appeared to be inclusion of the additional hypotheses of expansion of the universe and of multiple or superclustering, together with a more thorough investigation of the

effects due to errors of counting. They also found from further analysis that it was not necessary to assume the existence of clouds of internebular absorbing material.

Superclusters.—If only the brighter extragalactic nebulae to the 12th or 13th magnitude are considered, they show a tendency first noted in 1923 by J. H. Reynolds (1874–1949) to occur in a great-circle band around the sky. It is a belt of average width 12° that runs nearly perpendicular to the Milky Way, which it crosses in the northern constellation of Cassiopeia and again in the southern one of Circinus. The northern arc includes the Virgo cluster with its extensions to the south in Centaurus and to the north in Coma, Canes Venatici and Ursa Major. The southern part is less populous, but there are series of groups of bright nebulae in Andromeda, Pisces, Cetus, Sculptor and beyond into far-southern skies.

The possibility that these brightest nebulae may form in space an extended "metagalactic" system or cloud, which may also include the galaxy, has been suggested by a number of investigators. Chief among these are three Swedish astronomers of the Lund University observatory, K. Lundmark, E. Holmberg and A. Reiz. From studies during 1927–41 of single, double and multiple nebulae they concluded there is good evidence for such a large-scale organization. In shape it would be a flattened system of some tens of millions of light-years in diameter and one-tenth as thick. But this interpretation of the observations depended largely upon individual nebular magnitudes that later were found in some cases, and suspected in many others, to have large errors. Also there was some doubt about the completeness of the basic data for far-southern nebulae.

In 1952 G. de Vaucouleurs, at the Australian Commonwealth observatory, Mount Stromlo, Canberra, began a thorough reexamination of the question of a local supercluster, on the basis of newer and more accurate data. He redetermined the magnitudes of many of the brighter southern nebulae, and revised to a modern photometric system the magnitudes for most of the brighter catalogued nebulae. The aim was to achieve photometric consistency and completeness over the whole sky to about magnitude 12.5. His 1956 detailed discussion of this material gave strong support to the concept of a "local supergalaxy" that includes our own Milky Way stellar system. He proposed a model in which the great Virgo cluster may be "a dominant condensation not too far from its central region." If this is a valid assumption, then the galaxy in addition to being close to the principal plane of the supersystem, would be about three-fourths of the way from the centre to the edge, since the bright nebulae in the Coma-Virgo region around the north galactic pole were estimated to be three times more distant than some groups of large spirals in the opposite direction toward the south galactic pole. The over-all size of the supersystem was computed to be, on Hubble's distance scale, of the order of 25,000,000 light-years in diameter and one-tenth as thick. As additional independent evidence for a local supergalaxy, de Vaucouleurs pointed out the similarity in position and extent of a broad maximum of cosmic radio noise, reported in 1952 by R. Hanbury-Brown and C. Hazard, of Manchester, Eng., and also in 1953 by J. D. Kraus and H. C. Ko, of Ohio State university.

A local supercluster of bright nebulae including the galaxy may not be unique, for among the fainter ones Shapley in 1934 reported a distant, double supergalaxy in Hercules. Moreover, de Vaucouleurs' work in the southern hemisphere led him to suspect the presence of another supergalaxy, from a great, elongated swarm of nebulae extending through Cetus, Dorado, Fornax, Eridanus and Horologium. He estimated its distance to be only slightly greater than the Virgo cluster, and, from its apparent dimensions of 10° by 50°, a thickness and diameter of 1,600,000 and 8,000,000 light-years, respectively. De Vaucouleurs noted that the relative sizes and separations of this southern supergalaxy and the local supergalaxy appear to be comparable with Shapley's double supergalaxy in Hercules.

All the foregoing observational evidence, when added to that of the theoretical analysis of Neyman and Scott, suggests that superclustering, if not the dominating characteristic in the distribution of extragalactic nebulae, is a phenomenon that cannot be ignored in attempts to infer the structure of the universe.

V. THE EXTRAGALACTIC DISTANCE SCALE

Distances of extragalactic nebulae are most accurately determined from studies of objects within them that may be recognized and compared with their counterparts in the galaxy. These objects may be brightest stars, variable stars, star clusters, gaseous nebulae or novae. When these can be identified, their apparent magnitudes, m, are measured and compared with their absolute magnitudes, M, which are assumed to be the same as those for corresponding galactic objects. How the absolute magnitudes are obtained for the "comparison" galactic objects is a long story in itself. Here it will suffice to note that ultimately all astronomical absolute magnitudes depend upon distance determinations that in principle are equivalent to trigonometric surveying. By definition, M equals m at a distance of 32.6 light-years.

Once an extragalactic object's apparent magnitude is measured and its absolute magnitude assumed known, the distance, d, is computed from the simple formula

$$\log d = (m - M + 5) \div 5,$$

which assumes that the apparent brightness of an object varies inversely as the square of the distance. If there is reason to believe that somewhere along the line of sight to the extragalactic object there is matter that absorbs some of the light, a correction is determined or estimated for the apparent magnitude, which, of course, is made too faint by any obscuring material. Such matter may be present in the galaxy, in the extragalactic nebula whose distance is sought or, as Zwicky advocates, in internebular space. Correction for its effect often is difficult to make, and there may be considerable uncertainty even by the best procedure.

In practice, the use of individual objects within extragalactic nebulae for distance determinations is limited to a few hundred of the nearest and brightest nebulae. The vast numbers of extragalactic nebulae are so far and faint that even the largest telescopes cannot single out objects within them for individual study. Thus it is necessary to use other distance criteria, which may be apparent diameter, total magnitude (entire light of a nebula) and red shift. These quantities all have to be calibrated, or evaluated in terms of the distance criteria used for the nearer nebulae, before they can be used to obtain distances on an absolute scale of light years.

Hubble's Distance Scale.—In 1923 Hubble made the crucial observations with the 100-in. Mount Wilson reflector that are generally accepted as the first proof of the extragalactic nature of spiral and elliptical nebulae. He discovered in the great spiral nebula in Andromeda (Messier 31) a number of Cepheid variables. These are pulsating, intrinsically bright stars whose light varies characteristically, in periods ranging from a few days to months. Their importance as distance indicators depends upon the remarkable property that their periods are closely related to their brightnesses, in the sense that longer periods are associated with higher luminosities, as first found in 1912 by Henrietta Leavitt (1868–1921) of Harvard College observatory. She noted that for similar variables in the Small Magellanic Cloud, their periods were closely correlated with their apparent magnitudes, which meant with absolute magnitudes because the Cloud Cepheids are at essentially the same distance. Hubble compared the apparent magnitudes of Cepheids in M31 with those in the Cloud, and determined an average difference of nearly five magnitudes, equivalent to a relative distance factor of 10. Thus the Andromeda nebula was found to be ten times more distant than the Small Magellanic Cloud.

The estimation of distances in light-years for the spiral and Cloud, however, involved determination of Cepheid absolute magnitudes or luminosities. These had to be obtained from measurement of the motions of galactic Cepheids, and here, as became evident in 1952, was the surveying chain's weakest link. For galactic Cepheids are distant supergiant stars whose motions across the sky are so small that they are nearly lost in the errors of measurement. Nevertheless, their luminosities were estimated as early as 1913 by E. Hertzsprung of Potsdam. He had immediately

recognized the significance of Miss Leavitt's discovery for the determination of greater astronomical distances. It was his analysis of the available scanty data that yielded the first calibration of the invaluable Cepheid period-luminosity law. This result meant that in whatever object a Cepheid variable could be identified, determination of its period and apparent magnitude would yield a distance estimate in light-years. With this Cepheid criterion, Hubble in 1924 obtained a distance of 900,000 light-years for the Andromeda nebula.

Hubble's work on M31, and on several other large spirals and nearby systems in which Cepheids could be identified, represented only the opening gambit in his celebrated "preliminary reconnaissance of the observable region of the universe." Although he also discovered numerous novae and star clusters in the nearest extragalactic systems, and used them to supplement distance estimates based on Cepheids, he made the most far-reaching extension of the distance scale by developing two other distance criteria. These were brightest stars and total luminosities of extragalactic nebulae. The first meant what he judged to be the upper limit in luminosity for stars that could be individually distinguished on the best photographs with the largest telescopes. The second represented the average, intrinsic light of an entire extragalactic nebula.

These three criteria of Cepheids, brightest stars and total luminosities permitted establishment of the distance scale, with the 100-in. reflector, to about 1,000,000, 6,000,000 and 250,000,000 light-years, respectively. The last large leap was, of course, much more uncertain than the first small steps. Real brightnesses of entire stellar systems, unfortunately, are far from being nearly the same: they range over many magnitudes, probably as many as ten. Hubble ingeniously met the difficulty by using clusters of nebulae, for which average values of the apparent total magnitudes could be more reliably determined. He also was able to make reasonable estimates of the luminosities of the brightest cluster members. These were the only ones that could be detected at the optical limit of the 100-in. reflector: 500,000,000 light-years.

Revision of the Distance Scale.—In 1952 Hubble's colleague W. Baade reported to the International Astronomical union meeting in Rome that his observations with the 200-in. Hale telescope indicated the previously accepted distance of the Andromeda nebula was too small, probably by a factor of 2. A larger distance of 1,500,000 to 2,000,000 light-years seemed necessary to account for the fact that the 200-in. reflector was unable to reveal the RR Lyrae or cluster-type variables in M31. To understand the reason for this result, and its significance for the extragalactic distance scale, it is necessary to describe the background of the modern Cepheid period-luminosity law, which was formulated by Shapley on the basis of variable stars in the galactic globular clusters and Magellanic Clouds.

In the over-all picture of the astronomical distance scale for objects well beyond the possibility of distance determination by trigonometric techniques, the pulsating or Cepheid variables have long occupied a prominent position. Following Miss Leavitt's and Hertzsprung's work, Shapley in 1918 repeated the calibration of the Cepheid period-luminosity law and revised it from visual to photographic magnitudes. One of his purposes was to obtain distances of the galactic globular star clusters, in which large numbers of variable stars had been found photographically by Harvard workers, beginning in 1895 with S. I. Bailey (1854–1931). The great majority of these variables, however, generally had much shorter periods, in the range from a few tenths of a day to several days, and their fast light fluctuations resembled those of the noncluster bright variable star RR Lyrae. They were accordingly termed cluster-type or RR Lyrae variables, and sometimes "short-period" Cepheids. But the globular clusters also had a few variables of longer period, comparable to the "classical" galactic Cepheids. Shapley therefore made the assumption, which seemed reasonable on the basis of all available relevant data, that the cluster-type and classical Cepheid variables conformed to the same period-luminosity law. In form, its lower luminosity (short-period) end thus was fixed by the cluster-type variables observed in galactic globular clusters, and its middle and upper luminosity (longer-period) parts by the Cepheids in the Magellanic Clouds. Its calibration, or zero point, depended upon about a dozen classical galactic Cepheids for which proper motions, or across-the-line-of-sight velocities, had been measured.

From 1918–52 this "composite" Cepheid period-luminosity law was widely used, notably by Shapley in his comprehensive globular cluster investigations that established the size and extent of the Milky Way as a giant stellar system in which the sun was far out from the centre, and by Hubble in his extragalactic exploration that brought cosmology within the purview of observational astronomy. From time to time the details of the relationship were changed, but only slightly, by new, additional data, principally from the Magellanic Clouds. The zero point, or absolute magnitude calibration, also was intently scrutinized, without convincing conclusions that it was incorrect. But Baade's 1952 Rome report forced a re-examination of the roots of the relationship. As might be expected, the difficulty lay in the basic assumption that the same period-luminosity law is valid for both cluster-type and classical Cepheids. It was nature's sly trick to make it difficult for astronomers to find, in the same system, both types of variable star. Thus no cluster-type variables had been found in the Clouds prior to 1952, and even by 1965 none had been found in the Andromeda nebula with the 200-in. This failure to find cluster-type variables at the expected apparent magnitudes, about 17.5 in the Clouds and 22.5 in M31, meant there is a much greater difference in absolute magnitude between cluster-type and classical Cepheids than assumed in the composite period-luminosity law. The related questions of how much is the difference, and whether only the absolute magnitudes of the cluster-type variables, or only those of classical Cepheids, or both, need correction, had to be answered from other observations.

Baade's 1952 negative result for cluster-type variables in M31 was accompanied by a positive one that simultaneously yielded the size of the correction to the absolute magnitudes and indicated to which type of variable it should be applied. His 200-in. observations of M31 showed that the brightest, red giant stars like those in globular clusters—his population type II—have an apparent photographic magnitude of 22.5. Now this is just the figure to be expected from the accepted period-luminosity law if the brightest nonvariable stars in globular clusters average 1.5 magnitudes brighter than the cluster-type variables. This difference had already been found to be a good average value from previous observations in many galactic globular clusters. Finally, therefore, the cluster-type variables would be expected at magnitude 24 in M31, at 19 in the Clouds, and a zero-point correction of 1.5 magnitudes—in the brighter sense—should be applied to the absolute magnitudes of the classical Cepheids.

These results were revolutionary in nature and immediately led to a whole series of investigations concerned with other and independent checks on the suggested revision, and with the consequences for many of the problems of modern astronomy. Thus Baade's younger colleagues A. R. Sandage and W. A. Baum used the 200-in. to its limit to study in globular clusters stars so faint that they could be directly compared in colour and magnitude with similar nearby stars whose absolute magnitudes were known from trigonometric measurements. In this way they obtained in 1952–53 an apparently good check on the previously accepted absolute magnitudes of the cluster-type variables in the same clusters. Then in 1953, A. D. Thackeray and J. Wesselink discovered, with the 74-in. reflector of the Radcliffe observatory, Pretoria, S.Af., the first cluster-type variables in the Magellanic Clouds, at the expected apparent photographic magnitude of 19. Finally, for the classical Cepheids, A. Blaauw and H. R. Morgan in 1954 used more accurate proper motions for 18 of these variables and obtained a zero-point correction to their absolute magnitudes of 1.4 magnitudes, which agreed well with Baade's estimate.

By 1954 it was, therefore, quite clear that distances derived from classical Cepheids needed to be doubled. However, there still remained the question of how reliable are extragalactic distances for nebulae too far for detection of Cepheids, but close enough to show separately brightest stars. Their use as distance

indicators required: first, identification as single stars; second, determination of their apparent magnitudes; and third, knowledge of their absolute magnitudes. Since the latter could be estimated from counterparts in the galaxy, Magellanic Clouds and the spirals in Andromeda (M31) and Triangulum (M33), the problem was one of threshold discrimination and photometry with the largest telescopes. From observations with the 200-in., Sandage gave preliminary reports in 1954 and 1956 that strongly suggested still greater upward correction of Hubble's distance scale. On 100-in. reflector plates, many resolved objects that appeared to Hubble as stars were shown on 200-in. plates, taken by newer colour-filter techniques, to be gaseous nebulae—Strömgren's H II regions. Also, the old scale of apparent magnitudes was found to be seriously in error at the faintest limits. Both effects combined to give too small distances. These modern observations, however, require such critically good observing conditions that in 1956 Sandage had been able to obtain revised distances for only two spirals: 9,000,000 light-years for M81 in Ursa Major, and 20,000,000 light-years for M100 in Virgo. These distances are greater than Hubble's by factors of 4 and 3, respectively. When more of the nearer systems have been similarly observed, a more reliable average correction factor will result. Then it will be possible to rederive the absolute total magnitudes of nebulae for a more precise survey of the universe to its distant limits. But enough has already been learned from the 200-in. Hale telescope observations to demonstrate that astronomers have broken, by a significant margin, the billion (1,000,000,000) light-year distance barrier.

VI. RED SHIFTS AND EXPANSION OF THE UNIVERSE

In 1912 V. M. Slipher of the Lowell observatory, Flagstaff, Ariz., made the first spectroscopic observation of an extragalactic nebula for radial velocity. This is the speed in the line of sight obtained from measurement of spectral lines. According to Doppler's principle, when the lines are found to be of shorter than normal wave length, the source is approaching; when of longer, it is receding. Since the longer wave lengths are in the red part of the spectrum, a receding object exhibits a red shift of the lines in its spectrum. Because of their generally faint surface brightness, extragalactic nebulae are difficult objects for spectroscopic observations. Thus Slipher was able to obtain radial velocities for only a small number of the brightest spirals and ellipticals. At first he found radial velocities of approach and recession in about equal numbers, although the average velocity was appreciably greater than for stars. However, when he observed some fainter ones, with exposures of 20 to 30 hr., he obtained a most remarkable result: the velocities without exception were of recession and very large, some over 1,000 mi. per second. This discovery naturally aroused much interest, and numerous attempts were made to relate the recessional velocities to other characteristics of the nebulae, such as diameters and apparent magnitudes. But no convincing correlations were found, mainly because of the intrinsically large dispersions in these quantities. Progress toward understanding these red shifts came, as so often has happened in astronomy, from the establishment of a consistent distance scale.

Hubble's Law of Red Shifts.—Following his discovery of Cepheids in the Andromeda nebula in 1923, Hubble used the criterion of brightest stars to estimate distances of spirals. By 1929 he had distance data for 22 objects for which radial velocities also were available, chiefly from Slipher's work. The correlation between the two quantities was so close that Hubble in 1929 reported a velocity-distance relation for extragalactic nebulae. It was in the sense that the greater the distance, the larger the velocity of recession. Such a relationship had to some extent been foreshadowed from observational correlations of fewer and less precise data discussed by K. Lundmark and C. Wirtz, and by W. de Sitter's mathematical work using relativity theory. Hubble's new approach, however, clarified an obscure situation and laid a firm foundation for a spectacular advance involving very faint and distant nebulae. From 1928–36 Hubble measured total brightnesses of numerous nebulae in clusters to obtain increasingly greater distances, while his colleague M. L. Humason determined radial velocities with a spectrograph of radically new design. The results were of unprecedented interest: a straight-line relationship out to a distance of 250,000,000 light-years, and up to a velocity of recession of 26,000 mi. per second. Since this speed is nearly one-seventh the velocity of light, Hubble preferred the noncommittal term red shift and referred to his and Humason's results as the law of red shifts. It meant, in their 1936 formulation, that the distance of an extragalactic nebula, in millions of light-years, could be obtained by dividing its red shift, expressed in miles per second, by 100. With this work, the limit of the 100-in. reflector was reached, and the possibility of following the red shift still farther into space required more powerful optical resources. These were provided with the completion of the 200-in. Hale telescope in 1948.

In 1951 Humason resumed his red shift determinations, with the 200-in. and a nebular spectrograph in which more efficient Schmidt cameras and diffraction gratings were used instead of lenses and prisms. With this new equipment, Humason by 1955 had observed 20 extremely faint cluster nebulae whose red shifts are in the range from 25,000 to 38,000 mi. per second, in addition to many others of smaller red shifts. As an extension of Hubble's work, A. R. Sandage during the same interval measured apparent magnitudes of many faint cluster nebulae. All this work represented a very considerable increase in the amount, precision and range of the basic red shift-magnitude data, which justified a new analysis of the problem of the expanding universe.

Expansion of the Universe.—In relativistic cosmological theories it is generally assumed that the red shifts in nebular spectra represent velocities of recession, and that the universe is therefore expanding. On this basis modern cosmologists have worked out the details of a number of "model" universes. These differ in such properties as space curvature—whether the universe is bounded or infinite—and variation with time—whether it is static or evolving. In many cases the possibility of a model agreeing with the "real" universe depends upon departures from linearity of the relationships between observed quantities. A prime example is the red shift-magnitude relation: is it linear or is it curved, and in what sense? In 1956 Sandage reported the results of an analysis of his and Humason's data. He found that the relationship is essentially linear, except possibly at the extreme end where red shifts are of the order of one-fifth the velocity of light, and distances are of the order of a billion light-years. At this point there was some evidence that red shifts are getting larger than expected from a straight line fitted to the rest of the observations. If the effect is real, and correctly interpreted, it would be of high cosmological interest, because an apparently abnormal acceleration in red shift with distance could imply a deceleration in the expansion. This paradoxical result follows from the fact that when we go far out in space we also go far back in time. Thus if the most distant nebulae are found to be expanding faster, compared to the near ones, then the expansion in our own part of the universe has slowed down during the last billion years. Other important corollaries would be that the universe is not static but is still evolving, and that it is bounded rather than infinite.

Stellar Populations and Evolution.—In 1944 W. Baade, using the Mount Wilson 100-in. reflector to maximum advantage in a sky darkened by the wartime blackout, reported the resolution for the first time of the amorphous nuclear region of the Andromeda nebula into myriads of faint stars. His technique involved the use of photographic plates very sensitive to red light and long exposures under critically good conditions. At the same time he also resolved the several fainter elliptical companions of the large spiral. These were results of great importance, for they showed that the generally smooth and featureless light in elliptical nebulae and in nuclei of spirals comes from stars of a different kind than those forming spiral arms. In the latter the brightest stars are blue-white supergiants often enmeshed in dark matter, while in the nuclear regions and in elliptical nebulae the brightest stars are yellow-red giants. Since supergiant stars may be hundreds of times intrinsically more luminous than giants, it is easy to understand why elliptical nebulae were, and still are, so difficult

to resolve into stars, even with the largest telescopes.

Although Baade's observations represented a real telescopic triumph, his interpretation of them proved to be of surpassing significance. First, he stressed the close association of blue supergiants, interstellar material and diffuse gaseous nebulae in spiral structure, which he termed stellar population I. Second, he emphasized the similarities of the spherical distributions, colours and luminosities of the galactic globular cluster stars with the elliptical nebulae and nuclear region red giants, which he called stellar population II. These two populations also have dissimilar dynamics: type I participates primarily in the general rotation in the principal plane and has a small internal velocity dispersion; type II, on the other hand, shows little tendency toward general rotation and has a high internal velocity range. Thus type I is essentially a disk or fundamental-plane population, while type II is a halolike population surrounding and permeating the entire system. The distinction between the two populations, however, goes even deeper than their differences in spatial distribution and dynamics. As the result of much modern work stimulated by Baade's discoveries, it is known that the two populations represent separate stages in stellar evolution: type I is young, type II is old, and the age difference is measured in billions of years.

The blue supergiants of population I pour out radiation at so high a rate that they consume their hydrogen fuel in the astronomically short time of a few millions or tens of millions of years. These relatively brief lifetimes mean that some supergiants are continually forming in the spiral structure, otherwise we should not see them over such a long range in time as inferred from their distances. Since their formation and fleeting cosmic existence require enormous quantities of the basic fuel, hydrogen, the conclusion is almost inescapable that they originate from the hydrogen-rich interstellar gas and dust. The red giants of population II, by contrast, have reached a more mature state of life. They coolly maintain a high but not profligate standard of energy dispensation, thereby being rewarded with lifetimes hundreds of times longer. If they likewise originated from an interstellar medium, then their present properties suggest that they did so at a time far in the past, when the entire parent system consisted largely of a primeval and turbulent mass, rather than of a well-defined rotating thin disk.

Consideration of the evolutionary differences between Baade's stellar populations I and II leads naturally to the more general question of how a whole extragalactic system may evolve. In particular, it may be asked whether Hubble's classification scheme corresponds to an evolutionary sequence. Our knowledge still is too scanty, however, to provide a satisfactory answer, although there are indications that the problem of nebular evolution eventually may be successfully attacked by the same procedures used in studies of stellar evolution. Remarkable success was obtained during the decade 1950–60 by applying in astronomy the results from the rapidly developing field of physics concerned with element synthesis and atomic nuclear reactions. In this way astronomers obtained estimates of the ages of stars in galactic nebulae, open and globular clusters. Observationally, progress depended on the determination of precise colours and magnitudes for many stars in the groups, and upon more detailed spectroscopic analysis of their light. But such information for extragalactic nebulae is more difficult and takes longer to obtain, even with the largest telescopes.

This procedure involving colours, magnitudes and spectra of nebulae and their constituent parts represents a significantly different effort to understand nebular evolution. It studies the population characteristics and relates them to the observed nebular structure. Thus if the age properties of the populations are known, the structure may be related to age, and the various kinds of structures may be arranged chronologically. It remains to be seen, however, whether the great variety of nebular forms means a great range in age, or, as seemed more probable in 1965, whether the different structures denote the presence, in different proportions, of various age groups in the same system.

Rotation of Spiral Nebulae.—The most casual glance at photographs of spiral nebulae suggests rotation, which is readily revealed spectroscopically by Doppler's principle for systems tilted toward the line of sight. V. M. Slipher and Max Wolf in 1914 and F. G. Pease (1881–1938) in 1916 pioneered in proving that the central parts of several of the brightest spirals, including the Andromeda nebula (M31), have a component of rotation in the line of sight. Because of the extreme faintness of the nebular light, further progress was slow, and even by 1950 only the two nearest and apparently largest spirals, M31 and M33, had been studied in any detail, chiefly by observations made at the Lick observatory by H. W. Babcock, L. H. Aller and N. U. Mayall. They obtained radial velocities for a number of gaseous nebulae located in the plane of each spiral, and were able to follow the character of the rotation out to the extreme limits shown on photographs. Except for a faster spin in a small nuclear region in M31, they found that the two spirals rotated similarly: out to a certain distance from their centres, the rotational motion increased nearly uniformly, as for a solid body, but farther out the rotational velocity decreased, as for the planets in the solar system.

These two kinds of rotational motion reflect the distribution of mass: if it is more nearly spread out, solid-body rotation results; if highly concentrated toward the centre, Keplerian or planetary motion prevails. Comparison of these results with similar ones for the solar region of the galaxy, wherein an outwardly decreasing rotational motion is observed, gave additional support to the concept that the sun is located far from the galactic centre and beyond the main mass. Periods of rotation for the main bodies of M31 and M33 are 180,000,000 and 120,000,000 years, respectively, on the revised distance scale; for their outer parts, about 200,000,000 years, which is comparable to that for the sun's galactic orbit.

On the reasonable assumption of circular motion for the gaseous nebulae observed in the spirals, the latter's masses could be computed and compared with that of the galaxy. It was found that M31 and the galaxy are comparable giants, each having a total mass equivalent to 100,000,000,000 to 200,000,000,000 suns, but that M33, a more average spiral, contains mass aggregating about 3,000,000,000 to 4,000,000,000 suns. These rather crude optical observations, however, seem likely to be supplemented, or possibly replaced, by the more precise measurements made with the radio radiation from neutral hydrogen (*see* below).

Direction of Rotation in Spirals.—Closely allied with the character of the rotational motion of spirals is the question of how the movement takes place with respect to the curvature of the spiral arms; in other words, do the arms appear to be winding or unwinding? Slipher pioneered in this field, and on the basis of his rotation measures and his inferences of the true spatial orientation of the nebulae from their apparent or projected forms, he concluded that all spirals probably rotate in the same manner, namely, that the central part turns into the spiral arms like a coil spring being wound up. The interpretation of photographs of spirals to determine how the systems are located in space is not easy, however, and the criteria used by Slipher—asymmetries in the pattern of dark matter—were later (1934–40) construed in the opposite sense by Bertil Lindblad, whose theory of spiral stellar systems suggested a rotation with the arms leading instead of trailing.

The question was completely re-examined in 1942 by Hubble, whose study of the file of hundreds of large-reflector photographs disclosed four spirals suitable as test cases. In these the spiral pattern was plain, and the sense of tilt was unambiguously determined by primary and secondary dark lanes silhouetted against the bright nuclear region. From spectrographic observations of these four crucial-test spirals, made at the Mount Wilson and Lick observatories, it was found that, in each case, the arms trailed. With supporting, but not decisive, evidence provided by similar modern observations of 11 other spirals, Slipher's earlier conclusion now may be accepted as fairly well established, namely, that all spirals rotate in the same way: as the central part turns, the arms lag behind.

VII. RADIO OBSERVATIONS AND QUASI-STELLAR RADIO SOURCES

Neutral Hydrogen Radiation.—The first detection in an extragalactic source of neutral hydrogen radio radiation of wave length 21 cm. was accomplished in 1953 by the Australian radio astronomers F. J. Kerr and J. V. Hindman. They observed both Magellanic Clouds with a 36-ft. antenna that resolved regions about 1.5° in diameter, which is small enough to give information for individual areas of the considerably larger Clouds. They found that the amount of neutral hydrogen (H I) is about the same in both Clouds, but from the optical observation that there is apparently much more obscuring dust in the Large Cloud than in the Small, they concluded that the ratio of gas to dust is very different in the two systems.

The surface distribution of the H I gas in the Large Cloud was found to be similar in extent to the stars, while in the Small Cloud it appeared to extend well beyond the central body of stars, with a protuberance toward the Large Cloud. The depth distribution of the H I gas suggested an irregular and flattened disk seen nearly face-on for the Large Cloud, and a more regular, possibly spheroidal form for the Small Cloud. Kerr and Hindman also obtained radial velocity measurements of relatively high precision that made possible detailed studies of systematic motions in both Clouds.

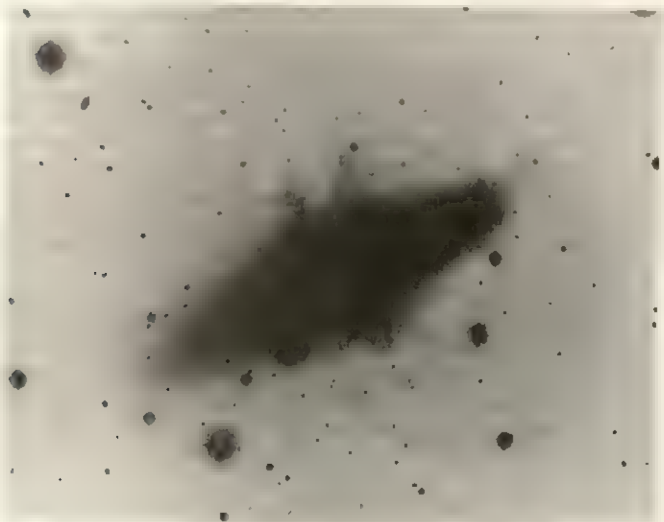
Radio Red Shifts.—In order to test as severely as possible by spectroscopic means the possibility that the red shifts observed in nebular spectra are due to recession, it is desirable to measure over as long a wave length range as possible the ratio of $\Delta\lambda/\lambda$. In this case $\Delta\lambda$ is the shift and λ the normal wave length of any spectral feature identified and measured. Doppler's principle predicts that if a shift is due to motion in the line of sight, then $\Delta\lambda/\lambda$ must be the same for all wave lengths. In the optical spectra of nebulae, it has been possible to investigate this ratio over a range of wave lengths that differ only by a factor of 2. Although $\Delta\lambda/\lambda$ has always been found constant to within the errors of measurement, even for the largest red shifts, astronomers realized that it would be of extraordinary cosmological interest if a fairly large red shift could be measured in the radio range of wave lengths, which are longer than light waves by a factor of several hundred thousands.

Although in 1955 and 1956 radio observations were reported of absorption lines of 21-cm. H I in Cygnus A and in the Coma cluster of nebulae, and their radio red shifts of 10,400 and 4,350 mi. per second, respectively, agreed closely with the optical values, subsequent work failed to confirm these first results. Nevertheless, more recent 21-cm. work on the brighter and nearer radio galaxies, chiefly by M. S. Roberts first with the 60-ft. antenna at the Agassiz station of Harvard university, and later with the 300-ft. transit-type antenna at the National Radio Astronomy observatory, Green Bank, W.Va., has shown excellent agreement between optical and radio red shifts. Thus, by 1965 Roberts had observed nearly 100 radio galaxies and had detected neutral hydrogen radiation in about 50% of them. Their red shifts ranged up to 1,000 mi. per second, and the comparison with optical values indicated that, within the observational errors, $\Delta\lambda/\lambda$ is constant for a radio-optical wave length ratio of 500,000. These observations of radio red shift greatly strengthened the interpretation of nebular red shifts as velocities of recession.

Discrete Sources.—A few years after the end of World War II radio astronomers found that the sky contains a number of discrete radio sources. These are distinguished from the general background of continuous cosmic radio radiation by their higher and localized intensities. But the first observations of the discrete sources gave only very crude positions and indications of size—much too imprecise to yield reliable correspondences with optical sources. The uncertainties were rapidly reduced, however, with the construction of larger antennas and by the development of interferometer techniques. In this way the Australian radio astronomers J. G. Bolton, G. J. Stanley and O. B. Slee in 1949 pinpointed two of the discrete sources with sufficient accuracy to make reasonably certain their correspondence with two known extragalactic objects. They suggested identification of the radio

sources Centaurus A and Virgo A with two peculiar elliptical nebulae: N.G.C. 5128 and N.G.C. 4486 (M87), respectively. The first of these is anomalous in having a great amount of lanelike dark matter, and the second is odd in showing a raylike jet extending from the nucleus. Why should these two elliptical nebulae, which are not exceptionally bright or large in the optical sky, be outstandingly bright in the radio sky? The most probable answer involves the recognition of two new phenomena in the universe beyond the Milky Way: (1) large-scale magnetic fields and (2) explosive events in nuclei of nebulae.

Large-Scale Magnetic Fields.—The discovery of polarized light from the galactic Crab nebula (*see* above) and the reasonable explanation of it as radiation from electrons accelerated in a magnetic field, raised the question of whether a similar phenomenon would be observed on the extragalactic scale. This possibility was considered by a number of investigators attending the International Astronomical Union symposium on radio astronomy, held



BY COURTESY OF THE MOUNT WILSON AND PALOMAR OBSERVATORIES

EXPLODING EXTRAGALACTIC NEBULA M82 (N.G.C. 3034) IN THE CONSTELLATION OF URSA MAJOR

Light from the outermost filamentary structure above and below the principal part of the nebula is nearly 100% polarized, as would be true for electrons moving in a magnetic field. Spectroscopic measurements of the radial motions of the inner-region filaments, composed mainly of hydrogen atoms, indicate that they were ejected from the nucleus about 1,500,000 years ago in nebular time, or 11,500,000 years ago in earth time, since the nebula's distance is 10,000,000 light-years. The farthest filaments are more than 20,000 light-years from the nucleus, and the total mass thrown out is equivalent to 5,000,000 suns. The photograph is a composite of three exposures in blue-violet light, taken with the 200-in. telescope

in 1955 in Manchester, Eng. The discussions led to a suggestion that Virgo A (N.G.C. 4486, M87) might be another case of a cosmic synchrotron because of the high ratio of radio to optical radiation, as in the case of the Crab nebula. The suspicion for M87 was effectively confirmed observationally by Baade. He reported in 1956 that 200-in. reflector photographs showed that the light in the raylike jet is polarized, probably to the order of 30%, and that the plane of vibration of the electric vector is nearly along the line of the jet.

A much more spectacular example of a cosmic magnetic field, and the first really convincing case for an explosive event that originated in the central region of an extragalactic nebula, is represented by N.G.C. 3034 (M82). This is an irregular-type nebula that is a distant and fainter companion to the large spiral in Ursa Major, N.G.C. 3031 (M81). Radio astronomers had located a faint source in the region and had naturally identified it with the larger and brighter M81. However, in 1961 C. Roger Lynds, working with more powerful equipment at the National Radio Astronomy observatory, Green Bank, W.Va., found that his more accurate position of the radio source put it very close to M82. Furthermore, he also observed that the intensity of its radio energy is nearly the same over a wide range of frequencies. Since such a "flat spectrum" is very rare, with the best-known examples being the Crab nebula and M87, he predicted that, like them, the light of M82 might be polarized. This prediction was confirmed in 1962 by Aina Elvius at the Lowell observatory, Flagstaff, Ariz., in the course of a more extensive program to detect polarization in extragalactic nebulae. She found that the light of the outer parts of M82 shows polarization up to 15%, a figure much higher than in any of the other nebulae on her program. It was the 200-in. Hale telescope, however, that revealed in 1964, by new photographic methods devised by A. R. Sandage and W. C. Miller of the Mt. Wilson and Palomar observatories, the 100% polarization of light in the very faint, extensive outer filamentary structure of M82, partially discovered in 1963 by H. M. Johnson using the old 36-in. Crossley reflector at the Lick observatory. These 200-in. telescope observations showed that this light from M82 met the two conditions required for synchrotron radiation from electrons moving in a magnetic field: (1) it is continuous, *i.e.*, comes from all wave lengths; and (2) the direction of the light vibrations is predominantly perpendicular to the pattern of filaments.

Explosive Events in Nuclei of Nebulae.—In 1943 C. K. Seyfert, working at the Mt. Wilson observatory, carried out a classical investigation of the spectra of a number of nebulae having a very high concentration of light toward their centres, or nuclei. His observations showed that these small and very bright regions contained, in addition to the usual increased numbers of stars, great masses of gas in violent motion, with velocities up to several thousand miles per second. At that time, the observations were able to indicate only that the gas motions in the nuclei are radial rather than rotational; the data were incapable of demonstrating a preference for inward or outward motion. The phenomenon was so unique, however, that this class of relatively rare nebulae came to be known as "Seyfert galaxies," and they directed attention toward nebular nuclei as sources of some kind of strange activity.

Baade's 200-in. telescope observations of the polarization of light in the jet of M87 led D. E. Osterbrock in 1960 to use the same telescope for spectroscopic study of the jet. He found its spectrum to be continuous, except at the very centre. There a radiation due to doubly ionized oxygen gas appeared to be composed of two parts: one that could be ascribed to the nebular nucleus, and another to a cloud moving outward with a velocity of nearly 600 mi. per second. The most reasonable interpretation of this abnormal velocity was that some of the ions and atoms of the jet structure, apart from the relativistic electrons, are being thrown outward at a high velocity by some unknown explosive process in the nucleus of M87.

By far the best-documented case of a nebular nuclear explosion is M82. In 1962 C. R. Lynds and A. R. Sandage reported spectrographic and photographic observations, made with the world's two largest telescopes, that left little doubt as to the occurrence of an enormous explosion in the centre of M82. Lynds used the 120-in. reflector of the Lick observatory to obtain spectra along the minor axis of the nebula to investigate any radial gas motions in the system. In this way he minimized the effects of general rotation in the principal plane, as reported by N. U. Mayall, of the Lick observatory, in 1960 from spectrographic observations along the major axis. Measurements of the $H\alpha$ line recorded on Lynds' spectrograms gave a remarkable result: the radial velocity increased linearly with distance from the centre, as would be expected for gas ejected in a single giant explosion. In the other part of this notable work, Sandage used the 200-in. telescope at Palomar observatory to obtain photographs with light from a narrow spectral region around $H\alpha$. These photographs showed a great, complex pattern of filaments fanning out from the centre of the nebula to large distances above and below the principal plane. Detailed study of both sets of data yielded estimates for the characteristics of the explosion: mass of material ejected = 5,000,000 suns; energy to accelerate this mass = 2×10^{55} ergs, or that equivalent to the thermonuclear conversion of hydrogen to helium for about 1,000,000 suns; energy of relativistic electrons = 10,000 Bev (billion electron volts); magnetic field strength = 1/100,000 to 1/1,000,000 gauss (earth's average mag-

netic field is $\frac{1}{2}$ gauss); and the time since outburst = 1,500,000 years. These results indicated a phenomenon of energy release on a scale fantastically greater than anything previously known, and they posed a real puzzle for astrophysicists to explain by known physical processes.

The case of M82, however, proved to be only the prelude to even more significant developments that came about by virtue of continued co-operation between radio and optical astronomers. These developments related to the so-called "radio stars," or discrete sources so small in angular size that radio telescopes could only place upper limits of a few seconds of arc on their diameters. For this reason such objects were referred to as "quasi-stellar radio sources." The recognition of their real nature in 1963 represented a major advance in modern astronomy as described in the next section.

Quasi-stellar Radio Sources.—The story of these phenomena may be said to have begun with the optical identification of one of the strongest and smaller radio sources known in 1951. In that year F. G. Smith of Cambridge university, Eng., determined a highly precise position for the discrete radio source Cygnus A, and he communicated the result to W. Baade and R. Minkowski, of the Mt. Wilson and Palomar observatories. Using the 200-in. Hale telescope, they were able to make an unambiguous identification of the radio source with a small 18th-magnitude nebula, on the basis of its unusual appearance and spectrum containing a number of emission radiations typical of a highly ionized gas. They also determined the red shift to be 10,500 mi. per second, which at once raised the hope that similar identifications of the fainter radio discrete sources would offer the best chances of obtaining red shifts greater than the largest one, 38,000 mi. per second, or 0.2 the velocity of light, known at that time (1952).

This expectation was realized eight years later when Minkowski in 1960 reported optical observations with the 200-in. telescope of the radio source 3C 295 (this designation refers to radio source number 295 in the third catalogue of such objects published by the radio astronomers of the Mullard Radio observatory, Cambridge, Eng.). This source is $\frac{1}{10}$ as bright and less than $\frac{1}{10}$ as large as Cygnus A; its optical counterpart was found to be the brightest member in an extremely faint cluster of nebulae, and of photovisual magnitude 20.5. So faint a magnitude meant that the light-gathering power of the world's largest telescope was strained to its utmost to yield a single spectral feature, an emission radiation from doubly ionized oxygen, for measurement of a red shift of 0.46 the velocity of light. Since optical spectra for objects fainter than magnitude 20 are bound to be nearly drowned out by the night-sky airglow, it seemed that a limit had been reached for red shifts of very distant extragalactic nebulae. This limit, however, had been extended in distance by at least a factor of 2, so that by 1960 astronomers could say that the universe had been probed out to a hazy horizon of several billions of light-years.

In the early 1960s radio observations of the fainter radio discrete sources rapidly became more precise in position and in indication of size. Also, many of the brighter and larger ones were definitely identified with elliptical, spiral and irregular extragalactic nebulae. In general, it was found that these radio sources could be put into two classes, weak or strong emitters, with the latter showing a marked preference for very small size. In fact, even with antenna arrays of several miles extent and used as interferometers, large numbers of the discrete radio sources often could not be resolved. However, the position accuracy could now be given to better than 1 min. of arc, which encouraged optical astronomers with access to large telescopes to use them for further identifications. It was in this way that A. R. Sandage, working closely with T. A. Matthews, of the Owens Valley Radio observatory, operated by the California Institute of Technology, Pasadena, Calif., found on photographs taken late in 1960 with the 200-in. telescope, that 3C 48 is a stellar object of 16th magnitude. Although there is some very faint and small nebulosity around it, 3C 48 was first thought to be a peculiar kind of galactic star.

During 1961–62 several more "radio stars" were identified with apparently stellar optical objects, some of which also had associated with them extremely faint wisps of nebulosity. The most interesting of these is 3C 273, identified by M. Schmidt of the Palomar and Mt. Wilson observatories, with the unexpectedly high brightness of 13th magnitude. Spectrograms of all these radio stars were obtained, and their spectra were found to be peculiar, with strong ultraviolet light and faint emission bands that defied identification. Nevertheless, there was little reason to regard these radio stars as other than galactic objects, possibly old novae or a different type of planetary nebula.

It was Schmidt who finally found the key to the puzzle of the "peculiar and uniquely new" spectra of the optical radio stars: certain emission bands in the spectrum of 3C 273 could reasonably be ascribed to the Balmer lines of hydrogen, but red-shifted by 0.158 times the velocity of light. This result meant that these quasi-stellar radio sources are extragalactic objects in which there is occurring a release of energy on a scale far beyond any previously found or imagined. If their distances are estimated from their red shifts, the quasi-stellar sources are intrinsically brighter by factors up to 100 times greater than any previously known extragalactic stellar system. If quasi-stellar radio sources with larger red shifts can be identified, astronomy has the means to probe to a distance many times farther than by observation of ordinary extragalactic nebulae. A step in this direction was taken in 1964 when Schmidt and Matthews reported a red shift for 3C 147 of 0.545 the velocity of light. Since this object is of the 18th magnitude, there was good reason to expect that in future years radio and optical astronomers will extend their discoveries to still greater distances in the universe. *See* QUASI-STELLAR RADIO SOURCES.

See also references under "Nebula" in the Index.

BIBLIOGRAPHY.—Galactic nebulae are treated in a number of books; one of the most readable, best illustrated and semitechnical is by B. J. and P. F. Bok, *The Milky Way* (1957); more technical ones are L. H. Aller, *Gaseous Nebulae* (1956) and J. Dufay, *Galactic Nebulae and Interstellar Matter* (Eng. trans., 1957). For extragalactic nebulae, a classic work is Edwin Hubble, *The Realm of the Nebulae* (1936) and also valuable is the account of work at Harvard university by Harlow Shapley, *Galaxies* (1943); for the latter, a modern, revised edition has been published as *The Inner Metagalaxy* (1957). Several more recent books in French are: G. de Vaucouleurs, *L'Exploration des galaxies voisines* (1958); Colloques Internationaux du Centre National de la Recherche Scientifique, *Les Recherches galactiques et extragalactiques et la photographie électronique* (1960); and G. Courtès, *Les Galaxies* (1964). More specialized is F. Zwicky's *Morphological Astronomy* (1957), and chapters in A. Beer's *Vistas in Astronomy*, vol. 2 and 3 (1956 and 1960), and in *Annual Review of Astronomy and Astrophysics*, vol. 1 and 2 (1963 and 1964). W. Baade's last work, a series of lectures at Harvard university, was edited by Cecelia Payne-Gaposchkin as *Evolution of Stars and Galaxies* (1963). An excellent review by G. R. and E. M. Burbidge, "Evidence for the Occurrence of Violent Events in the Nuclei of Galaxies," was published in *Reviews of Modern Physics* for October 1963. The most up-to-date technical books are two compilations of symposium papers: G. C. McVittie (ed.), *Problems of Extra-Galactic Research* (1962) and Ivor Robinson (ed.), *Quasi-Stellar Sources and Gravitational Collapse* (1965). Concerned with theoretical or cosmological matters are, in order of increasing technicality, G. Gamow, *The Creation of the Universe* (1952); P. Couderc, *The Expansion of the Universe* (Eng. trans., 1952); and G. C. McVittie, *General Relativity and Cosmology* (1956). (N. U. M.)

NECESSITY. For ethical implications of this term *see* FREE WILL and DETERMINISM. For logical necessity *see* first SYLLOGISM, and then LOGIC; LOGIC, HISTORY OF. For God as the Necessary Being *see* THEISM; also RATIONALISM. For mythology *see* FATE.

NECHO (NEKO; Gr. NEKOS; Assyrian NIKU) was the name of two Egyptian Pharaohs of the 26th dynasty:

NECHO I, perhaps a Libyan by origin, was installed by the Assyrians as prince of Sais and Memphis *c.* 670 B.C. He rebelled and was carried captive to Nineveh but was reinstated by Ashurbanipal.

NECHO II (Wahibre), the son of Psamtik I, reigned 610–595 B.C. Herodotus (ii, 158) tells of his attempt to link the Nile with the Red sea by a canal, and states (iv, 42) that under his patronage Africa was first circumnavigated. His ambition to revive Egyptian influence in Asia led him to march to the help of the Assyrians making their last stand at Harran. On the way he defeated and killed King Josiah of Judah, who attempted to bar

his way at Megiddo (II Kings xxiii, 29). After some successes in the Euphrates area, his army was decisively beaten at Carchemish (*q.v.*) in 605 B.C. Four years later a Babylonian force under Nebuchadrezzar II threatened Egypt but was driven back. Necho died in 595 B.C. *See* also EGYPT: *History: Ancient Period.*

See D. J. Wiseman (ed.), *Chronicles of Chaldaean Kings (626–556 B.C.) in the British Museum* (1956). (M. S. DR.)

NECK, in geology, the denuded stump of an extinct volcano. Beneath every volcano there are passages or conduits up which the volcanic materials were forced, and after the mass has been leveled by erosion there is a more or less circular pipe which marks the site of the crater. This pipe, filled with ashes or lava, is the characteristic of a volcanic neck.

In regions of former volcanic activity necks are the most persistent of all volcanic structures because the active volcanic magma is located deep within the earth's crust and the pipe by which it rises to the surface is of great length and traverses a great thickness of strata. This extensive pipe was usually vertical and nearly uniform in diameter for great depths; when exposed by denudation it has a circular ground plan, or if shown in vertical section (or elevation) in a cliff it is a pillar-shaped mass crossing the bedding planes of the strata nearly at right angles. It terminates upward in the remains of the volcanic cone and communicates below with the reservoir from which the lavas were emitted, represented in most cases, where it has been exposed, by a large irregular mass (a batholith or boss) of coarsely crystalline igneous rock. The site of such a neck is generally indicated by a low conical hill consisting of volcanic rock, surrounded by sedimentary or igneous strata of a different kind. The low cone is due to the greater hardness and strength of the volcanic materials and is not connected with the original shape of the volcano. Two splendid sugar-loaf cones known as the Pitons of St. Lucia, in the West Indies, rising from the sea with almost vertical sides to a height of nearly 3,000 ft., are old volcanic necks. In the United States (in Texas, New Mexico, Arizona, California and other western states) geologists have observed conical volcanic hills having all the features which belong to necks. In the British Isles examples are found in Derbyshire, Fife, the Lothians and the Glasgow district with the remains of Carboniferous volcanoes in every state of preservation.

Some have the conical hills of lavas and ashes well preserved (*e.g.*, Largo Law in Fifeshire); others retain only a small part of the original volcanic pile (*e.g.*, Arthur's Seat, Edinburgh; the Binn of Burntisland); and of the larger number nothing remains but the neck.

Where the volcanic rocks are soft and easily disintegrated the position of a neck may be indicated by a cup-shaped hollow.

The size of necks varies considerably; the smallest may be only 20 or 30 yd. in diameter, the largest are several miles. Occasionally a whole neck is composed of solid crystalline rock representing the last part of the magma which congealed within the crater. The Castle rock of Edinburgh is a neck occupied by a plug of crystalline basalt. Necks of this kind weather down very slowly and tend to form prominent hills. A particularly famous example is Devils Tower National monument (*q.v.*), in Wyoming.

After the eruptions terminate, gases or hot solutions given out by deep-lying masses of molten rock may find a passage upward through the materials occupying the crater, greatly modifying their mineral nature and laying down fresh deposits (*see* METASOMATISM). A good example of secondary deposits within a volcanic neck is provided by the Cripple Creek mining district of Colorado. The ore-bearing veins are connected with volcanic rocks and part of these occupy a vertical circular pipe which is a typical volcanic neck. A phonolitic breccia, greatly altered, is the principal rock and is cut by dikes of phonolite, diabase (dolerite), etc. The country rock is mostly granite and gneiss, and blocks of these are common in the breccia. A large volcano was built up in Tertiary times on the granite plateau and has since been almost entirely removed by denudation. The gold ores were carried upward by currents of hot water derived from the volcanic magma and were deposited along cracks and fissures in the materials which occupied the crater, and also in the surrounding rocks. *See* also GEOLOGY; ORE DEPOSITS. (J. S. F.; X.)

NECKAM, ALEXANDER (1157–1217), English schoolman and scientist, author of *De naturis rerum*, was born at St. Albans, Hertfordshire, in Sept. 1157 on the same night as King Richard I. His mother, Hodierna, was foster mother to the prince, who later gave her lands in Wiltshire, which long bore her name: Knoyle Odierne. Alexander was educated at the school at St. Albans and studied at Paris (*c.* 1175–82). Returning to England, he was master at a monastic school at Dunstable (*c.* 1183–84) and then at St. Albans. He taught theology at Oxford (*c.* 1190) and entered the Augustinian abbey of Cirencester (*c.* 1200), of which he became abbot in 1213. He died at Kempsey, Worcestershire, early in 1217. His earliest work, *De nominibus utensilium*, is a school book, a list of words having to do with daily life, strung together to form sentences. It contains the earliest European notice of the use of the magnetic compass as a guide to seamen. His other voluminous works, in prose and verse, which are mainly unpublished, were theological or moral. They include a grammar for biblical students (*Corrogationes Promethei*) and commentaries on the Psalms, Proverbs, Ecclesiastes and the Song of Solomon. The two introductory books of the commentary on Ecclesiastes are entitled *De naturis rerum*. In the course of moralizing comments on the heavens, on animals, birds, fishes and on man he shows that he was acquainted with the new scientific knowledge that was becoming available in western Europe through the efforts of translators from the Greek and Arabic, and in his case especially through writers of the medical school of Salerno. The commentaries also show that he knew well a wide range of Latin classical writers. His works were copied and read in England till the end of the middle ages. The name Neckam is a late corruption of his nickname "Nequam."

(RI. W. H.)

NECKAR, a river of Germany, 371 km. (230 mi.) long and a right-bank tributary of the Rhine, rises in the Black Forest near Schwenningen am Neckar and close to the headwaters of the Danube. It flows north and then northeast along the foot of the Jurassic scarp of the Swabian Jura mountains, passing Rottweil, Rottenburg and Tübingen. At Plochingen it changes its course, flowing away from the scarp edge to Bad Cannstatt near Stuttgart. The valley at this point is very picturesque. It becomes broader and deeper and lies between vine-clad hills. Continuing north past hills crowned by feudal castles, it flows by Heilbronn and Bad Wimpfen to Eberbach. It there takes a tortuous westerly course and cuts through the wooded hills of the southern end of the Odenwald. Winding by Neckarsteinach and Neckargemünd between wooded heights, it sweeps beneath the Königsstuhl (1,857 ft.), washes the walls of Heidelberg, and enters the Rhine trough from the right at Mannheim. The Neckar is canalized as far as Plochingen, and is navigable for 1,000-ton barges. The construction of a canal to link Stuttgart with Ulm is being undertaken (*see* RHINE). (R. E. DI.)

NECKER, JACQUES (1732–1804), the French king Louis XVI's minister of finance, overpraised in his lifetime for his somewhat dubious skill with the public finances and unduly depreciated by historians for his alleged vacillation and lack of statesmanship in the opening phases of the French Revolution. He was born in Geneva on Sept. 30, 1732, the younger son of C. F. Necker, a lawyer from Küstrin in Brandenburg who, after appointment to the chair of German public law in the University of Geneva, had become a citizen of the Genevan republic in Jan. 1726. At the age of 16, Jacques Necker entered the bank of his father's friend Isaac Vernet as a clerk; and in 1750 he was transferred to the bank's headquarters in Paris. On Vernet's retirement in 1762 his nephew Pierre Isaac Thellusson promoted Necker to the position of junior partner. As a result of adroit speculation in the public funds and in the grain trade, Necker became a prominent and wealthy banker. In 1764 he married Suzanne Curchod, the cultivated and talented daughter of a former Vaudois pastor

(among her earlier suitors had been the historian Edward Gibbon). She encouraged him to embark on a public career. Geneva appointed him its resident minister in Paris in 1768; and he also became a director of the French East India company. In 1772, at his wife's suggestion, Necker transferred his banking responsibilities to his brother Louis. He then acquired a reputation as a writer on financial topics by an éloge of Colbert, which won the approval of the Académie Française (1773), and by an attack on Turgot's free-trade policy in corn (1775). Though he was a foreigner and a Protestant, Necker was placed in virtual control of French finances, as director of the royal treasury, on Oct. 22, 1776; and this position was recognized by his appointment as director general of the finances on June 29, 1777.

In his first ministry Necker made several cautious experiments in social and administrative reform. He abolished *mainmorte* (mortmain) on the royal domains in Aug. 1779; reduced the numbers of the general tax farmers from 60 to 40; and established "provincial assemblies" for Berry and for Haute-Guienne with administrative powers in which the third estate had as many representatives as the clergy and the nobility combined and voting was by head (1778–79). The first and the last of these experiments met with opposition from the privileged orders and were not extended, as had been hoped, to the country as a whole. The main mistake made by Necker, however, was his misguided attempt to finance French participation in the American War of Independence without recourse to additional taxation. In trying to raise the necessary loans, Necker published in 1781 his celebrated *Compte rendu au roi*, claiming a surplus of 10,000,000 livres in the hope of concealing an actual deficit of 46,000,000. The opposition of the leading minister, Maurepas, and the hostility of the queen, Marie Antoinette, forced Necker to resign on May 19, 1781. He retired to St. Ouen, where he wrote his *Administration des finances* to justify his policy (1784).

After both Calonne and Loménie de Brienne had failed to solve the financial problems, for which Necker was at least partially responsible, Necker himself was recalled as finance minister on Aug. 26, 1788. As the decision to summon the estates-general for 1789 had already been taken (*see* FRANCE: *History;* FRENCH REVOLUTION), Necker's main preoccupation lay in the field of politics rather than in finance, though he was too complacent in assuming that the surrender of the fiscal immunities of the nobility would remove his financial anxieties. In preparing for the meeting of the estates-general, Necker had to steer a difficult course between the claims of the third estate for double representation, which were conceded by the royal council on his recommendation in Dec. 1788, and the insistence of the privileged classes on the traditional method of debate, order by order. He has often been blamed for not having clearly laid down the government's proposals for political as well as financial reform in his opening speech to the estates-general on May 5, 1789. He did, however, propose a reasoned program of social and constitutional reforms which were lost sight of in the struggle over procedure. Even the latter struggle might have been avoided if Necker's suggestion for conciliation had been adopted. Similarly his program of liberal concessions to the National Assembly (formed between June 10 and June 17) was drastically modified by the court reactionaries just before the "royal session" of June 23, 1789. His objective was a limited constitutional monarchy with a bicameral legislature on the English model. His dismissal, on July 11, 1789, an overt sign of court reaction, did much to provoke the disturbances in Paris which culminated in the storming of the Bastille. Having retired to Switzerland, he received the summons to return to office on July 20, 1789.

In his third ministry Necker struggled ineffectively with the rapidly mounting deficit and was overshadowed by Talleyrand and Mirabeau, who dictated revolutionary finance at that stage. Necker's chief weakness as a politician was his vanity and his anxiety to preserve his popularity at all costs. After his final resignation (Sept. 18, 1790), he lived in retirement at Coppet near Geneva with his daughter Germaine, Mme de Staël (*q.v.*). Necker died at Coppet on April 9, 1804.

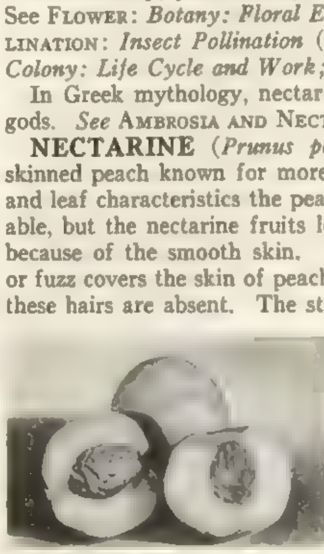
Terroine, *Recueil de documents relatifs aux séances des états-généraux, mai-juin 1789*, vol. i (1953). For Necker's first ministry *see* H. Glagau, *Reformversuche und Sturz des Absolutismus in Frankreich, 1774–1788* (1908); for his second, J. Flammermont, article in *Revue historique*, vol. xlvi (1891); for his financial policy after 1789, M. Marion, *Histoire financière de la France*, vol. ii (1919). (A. GN.)

NECROSIS is a term used in pathology to describe the death of a circumscribed area of tissue. It may result from loss of blood supply to an area, from toxic agents, from physical trauma or from the action of bacteria. The characteristic changes of necrosis are due to the activity of intracellular enzymes and consist for the most part of a breakdown of organic material of the nucleus and cytoplasm of the cell. *See* also GANGRENE. (F. L. A.)

NECTAR, in botany, a sweet, variably viscous liquid secreted by certain glands called nectaries in plants. Nectar serves as an insect attractant and thus aids in effecting pollination. It is the basis of honey, produced by enzymatic action in the honeybee. See FLOWER: *Botany: Floral Envelope* (*Accessory Organs*); POLLINATION: *Insect Pollination* (*Entomophily*); BEEKEEPING: *The Colony: Life Cycle and Work;* HONEY.

In Greek mythology, nectar refers to the nourishment of the gods. *See* AMBROSIA AND NECTAR.

NECTARINE (*Prunus persica* var. *nectarina*), a smooth-skinned peach known for more than 2,000 years. In tree shape and leaf characteristics the peach and nectarine are indistinguishable, but the nectarine fruits look more like plums than peaches because of the smooth skin. A velvety mat of epidermal hairs or fuzz covers the skin of peaches, while on the skin of nectarines these hairs are absent. The stones and kernels of the two fruits are alike in appearance. Like peaches, nectarines have red, yellow or white flesh and have a characteristic aroma and flavour. They are adapted to the same soil and climatic conditions suitable for peaches and require the same cultural treatments for successful production. There are clingstone and freestone nectarines. When some peach clones are crossed or self-pollinated, the resulting seeds that carry the factor for smooth skin may give rise to nectarines, while those that do not carry this factor will be peaches. Nectarines may sometimes appear on peach trees as a result of the process of bud variation or bud sporting, a vegetative deviation from the normal. Peaches occasionally occur spontaneously on nectarine trees in the same manner.



J. HORACE MCFARLAND CO.

NECTARINE (PRUNUS PERSICA VAR. NECTARINA)

Fruits of the nectarine are more subject to fungus diseases than peaches, particularly brown rot, and when grown in humid regions must receive frequent sprays of fungicides and insecticides to control diseases and insects. Stanwick, Quetta, Gold Mine, Fireglobe and Le Grande are well-known kinds in California. In the eastern United States, Cavalier and Garden State are better-adapted varieties for humid conditions. Cultivation of nectarines is essentially the same as for peaches (*q.v.*). (F. P. C.)

NEDIM, AHMED (1681–1730), Turkish poet, whose poems present a vivid picture of the wealth and elegance of early 18th-century Istanbul. Born in Istanbul, the son of a judge and brought up as a scholar, he won the patronage of the grand vizier Ibrahim Pasha, who gave him an appointment, and became a prominent figure in the so-called "Tulip age" under Ahmed III. He died in obscure circumstances in 1730, the year of the revolution led by Patrona Halil. He was that rare thing—a poet of the old school who freed himself sufficiently from its fetters to be able to express his personality in a style of great beauty. His *Kasides* (odes) and *gazels* (lyrics) are bright and colourful, and he excelled in his gay and lively *sharkis*, which are still sung. His masterly handling of the language has made him the most popular of divan poets.

His *Divan* was edited by Halil Nihad in 1922.

See E. J. W. Gibb, *A History of Ottoman Poetry*, iv (1904). (F. I.)

NEDIM PASHA, MAHMUD: *see* MAHMUD NEDIM PASHA.

NEEDLE: *see* CLOTHING MANUFACTURE; KNITTING; NET; SEWING MACHINE.

NEEDLEWORK, or work done with a needle and thread, generally implies a handcraft. Art needlework includes the decorating of fabrics by embroidery stitches or patchwork; and the various methods of forming a single thread into fabric or lace, the best known of which are knitting, crocheting and tatting.

Embroidery.—Embroidery is an art, or craft, known to all countries and periods of history; and modern embroidery, it may be pointed out, is regaining the status of an art expression. The old techniques are used with new fluidity and freedom, often with stunning effect.

The design is usually marked on the fabric first, except in canvas embroidery or cross-stitch work, in which the commonest practice is to copy the design by counting stitches and background threads. Embroidery stitches, beginning with the basic ones (*see* fig. 1), have an infinite number of variations, combinations, uses and methods of execution. For instance, tent stitch is also the petit point of canvas embroidery, and cross-stitch (*gros point* in canvas embroidery) looks like tent stitch crossed; the two, however, are executed differently and have distinctive needle directions. Chain stitch is commonly seen in single lines, but many oriental hangings and rugs are made of chain stitch worked in close-laid rounds or back and forth.

Satin stitch and long-and-short stitch, almost invariable additions to "white work" and eyelet embroidery, are also responsible for the most opulent silk- and metal-thread effects in church vestments, hangings, etc., as well as for the colourful crewel work and for most of the older "pictures in stitches" not done in petit point. Couching stitch allows heavy yarns, even cords, to be attached without being passed through the fabric. Buttonhole stitch is used to edge cut-out designs and form bars in cut work, done on linen.

FIG. 2.—STEPS IN KNITTING: (A) MAKING THE FIRST STITCH, (B) CASTING ON FIRST ROW OF STITCHES, (C) SECOND NEEDLE INSERTED INTO FIRST STITCH, (D) YARN BROUGHT AROUND NEEDLE TO START SECOND ROW, (E) PURLING AND (F) STOCKINETTE STITCH

Other forms of decoration through stitches are (1) drawnwork, in which threads are pulled out of the fabric in a design (this includes hemstitching); (2) smocking, in which gathers are drawn up and assembled, with the help of decorative stitches, into groups to form a design; and (3) appliqué, in which pieces of fabric, usually in contrasting colours, are cut into designs and attached to the background with either a sewing or an embroidery stitch. (*See* also EMBROIDERY.)

Knitting and Crocheting.—Both these forms of needlework require forming loops out of thread or yarn and drawing them through each other. The slender rods (needles, hooks; *see* below) by means of which this work is done range from wire thin (metal), used with fine thread, to finger thick (wood or plastic), for heavy yarns. Medium-sized plastic or metal needles and hooks and medium-weight yarns are most commonly used. Knitted fabrics have much more elasticity and pliability than crocheted ones, hence, knitting commonly is used for close-fitting garments, such as stockings and sweaters, and draped ones, such as dresses. Crochet work, on the other hand, offers greater variety in stitch design.

The information that follows should enable a person to work from printed instructions for making a simple knitted or crocheted article. The "gauge" (number of stitches and rows per inch) given in such instructions results from the combination of size of yarn, size of needle and the tightness or looseness with which an individual worker forms her stitches. Ideally a stitch is just loose enough to allow the needle or hook to slip through easily.

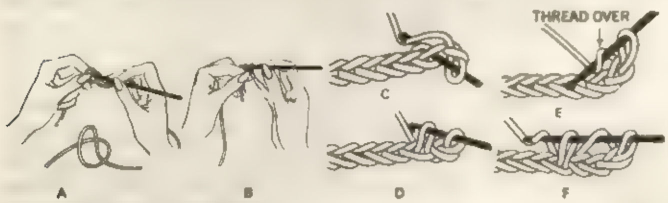
Knitting.—Knitting is done with knitting needles, which come either in pairs, used for flat, back-and-forth work; or in sets of four or more, used for work in rounds, such as socks and mittens. Large circular work, such as a skirt, is done on a circular needle. Flat work is easiest, and the beginning knitter should practise flat knitting first.

The work begins with casting on, or placing the first row of stitches on the needle. After making the first stitch (fig. 2A) and drawing it up, proceed as in fig. 2B for as many stitches as needed. The needle with the stitches on it is then changed to the left hand, the empty needle inserted into the first stitch (fig. 2C) and the yarn brought around (fig. 2D); the empty needle then forms a loop with the yarn and slips the old stitch off the left needle. This motion is repeated until all the stitches have been worked off the left needle and a second row is formed. The needles again change

hands for the next row, and so on. This plain back-and-forth knitting is called garter stitch. Purling is knitting in reverse, the yarn being held in front and the needle going through from back to front, as shown in fig. 2E. Alternately knitting one row and purling one row is stockinette stitch (fig. 2F).

To increase in knitting, the knitter knits two stitches in one stitch of the preceding row. To decrease, the needle is put through two stitches in the preceding row to form one new stitch. To slip a stitch means to lift it from the needle without knitting it. To pass slipped stitch over (another way of decreasing), the knitter knits one more stitch and with the left needle brings the slipped stitch over the knitted stitch and over the tip of the needle. To cast off or bind off the knitter knits or purls two stitches and passes the first stitch over the second; knits or purls another stitch; and repeats until only one stitch remains. The yarn is then broken off or cut and the end drawn through the loop. (*See* also KNITTING.)

Crocheting.—Crochet is the French word for "hook," the implement with which crochet work is done. The work starts with a crocheted chain (figs. 3A and B), except in cases where it is done



BY COURTESY OF COATS & CLARK, INC

FIG. 3.—STEPS IN CROCHETING: (A) MAKING THE FIRST LOOP ON THE HOOK; (B) STARTING THE CHAIN; FOR SINGLE CROCHET, (C) PUTTING THE HOOK THROUGH A STITCH IN THE PRECEDING ROW TO CATCH THE THREAD AND DRAW IT THROUGH; (D) CATCHING THE THREAD AGAIN AND DRAWING IT THROUGH BOTH LOOPS ON THE HOOK; FOR DOUBLE CROCHET, (E) WINDING THE THREAD AROUND THE HOOK AND (F) CATCHING THE THREAD

on an existing article (a handkerchief, a garment, a covered ring, etc.). When the chain is made to the length indicated, the work proper begins. (Note: in counting stitches, the loop on the hook is omitted).

For single crochet, the hook is put through a stitch in the chain or the preceding row, the thread or yarn is caught (fig. 3C) and drawn through, then caught again (fig. 3D) and drawn through both loops on the hook. For double crochet, the thread is wound once around the hook ("thread over," fig. 3E) before the hook is put through the stitch; the thread is then caught (fig. 3F) and drawn through two loops at a time until one loop remains on the hook. In treble crochet the thread is wound twice around the hook before it is put through. Half-double crochet starts the same way as double crochet, but after the first three loops are placed on the hook the thread is caught and drawn through all three at once.

Tatting.—Tatting, although classed as needlework, is done with a shuttle, with which knots and loops are formed into designs. Braids for upholstery and clothing formerly were done in tatting, but nowadays this work is mostly limited to fine white edgings

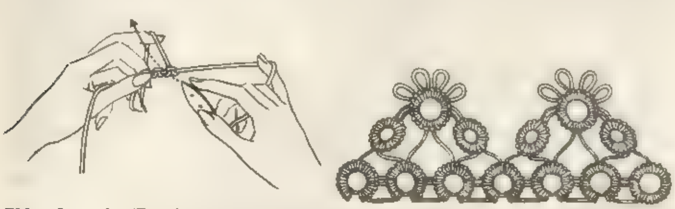


FIG. 4.—(LEFT) A CHARACTERISTIC HAND POSITION IN TATTING AND (RIGHT) A SAMPLE OF FINISHED WORK

for handkerchiefs, blouses and fine linens. Instructions cannot be given within the limits of this article; fig. 4, however, shows a characteristic hand position and finished work. *See* also LACE.

ÑEEMBUCÚ, the southwestern department of Paraguay, is bounded by the Paraná and Paraguay rivers which provide a 250-mi.-long river frontage and separate it from Argentina to the south and the west. Its area (5,355 sq.mi.) of flood plain provides the terrain for a cattle-raising economy, but subsistence agriculture also supports many of the people ([1962] 58,621); one-tenth of whom live in or near Pilar, the departmental capital. This town is linked to the Asunción-Encarnación road, but otherwise Ñeembucú lacks the transport routes which would enable its fertility to be utilized more fully. (G. J. B.)

NEENAH: *see* MENASHA.

NEER, the family name of several Dutch artists of whom the following are the two most important.

AERT (AERNOUT) VAN DER NEER (1603/04–1677) was born in Amsterdam but as a youth was in the service of a noble family at Gorinchem. He may have begun to paint before leaving Gorinchem but does not seem to have devoted himself to it seriously until he moved to Amsterdam, probably soon after 1630. At about this time he married Elisabeth Goverts, who bore him six children. He continued to live in Amsterdam until the time of his death (Nov. 9, 1677), but was unable to make a reasonable living from his art. From 1658 to 1662 he kept a wineshop, but this venture ended in disaster, and he went bankrupt in Dec. 1662, being discharged the following year. Subsequently he appears to have reverted to painting, for he is described as a painter in the inventory that was made of his few belongings at the time of his death. The artists who most influenced his early period were the Gorinchem painters Govaert and Raphael Camphuysen, while another noticeable influence is that of Esaias van de Velde.

Apart from a number of accomplished winter scenes with skaters, he specialized in canal and river landscapes seen by the light of late evening or early dawn, or (most characteristic of all) by moonlight. Within this limited range he has no rival among his contemporaries, his best pictures being distinguished by his sensitive grasp of composition as well as his delicacy and tenderness in handling the problems of subdued light, with its reflections on water and in the windows of riverside houses.

EGLON HENDRICK VAN DER NEER (1634–1703), eldest son of Aert van der Neer, was born in Amsterdam. He studied first under his father and then under the genre and portrait painter Jakob van Loo, but he does not betray the influence of either of them to any extent in his own paintings. He found his inspiration mainly in the works of artists of an older generation, producing genre pieces in a manner reminiscent of, though inferior to, Gabriel Metsu and Gerard Terborch and landscapes, sometimes with biblical or classical themes, in a style which seems with little doubt to have been based on that of Adam Elsheimer. He married three times and traveled extensively, working at different periods in Amsterdam, The Hague, Rotterdam and Brussels.

In 1687 he was accorded the title of court painter to Charles II of Spain. He died on May 3, 1703, in Düsseldorf, where he had been appointed court painter in 1690. (R. E. W. J.)

NEERWINDEN, a village of Belgium, famous for two battles, is situated 2 mi. N.W. of Landen, between Liège and Louvain. Pop. (1961) 1,009. It was in the duchy of Brabant during the period of Habsburg (Spanish and Austrian) rule in the Netherlands but is now in the Belgian province of Liège.

At the first battle of Neerwinden, in the War of the Grand Alliance, the allies under William III of England were defeated by the French under the duc de Luxembourg on July 29 (new style; 19, old style), 1693. At the second battle of Neerwinden, in the French Revolutionary Wars, the French under Dumouriez were defeated by the Austrians under Prince Josias of Coburg and Graf von Clerfayt on March 18, 1793.

NEES VON ESENBECK, CHRISTIAN GOTTFRIED (1776–1858), German botanist and entomologist best known as a mycologist, was born at Erbach on Feb. 14, 1776, and was educated at Darmstadt and at Jena, where he took the degree of M.D. After practising medicine he was appointed professor of botany in Erlangen in 1816, in which year appeared his *System der Pilze und Schwämme*. In 1819 he became professor of natural history in Bonn. Nees von Esenbeck was one of the early workers on the functions of spores in fungi. In 1820 he sowed *Rhizopus nigricans* on bread and obtained ripe sporangia in three days. He discovered

the spermatozoids of *Sphagnum* in 1822. In 1831 he was made professor of botany in the University of Breslau. He became one of the chief representatives of nature philosophy. His best-known works are those dealing with the fungi, the Hepaticae and the Glumiferae. He was the first to use the term "ascus" (or sac-containing spores) to characterize one of the three main divisions of fungi. For his political activities in 1848, a year of revolution and riots, Nees von Esenbeck was deprived of his professorship in 1851. He died in Breslau on March 16, 1858.

NEFERTITI (NOFRETETE), wife of the Egyptian king Ikhnaton (*q.v.*), is renowned for the beauty of her portrait busts, the best known of which, of painted limestone, is in the Dahlem museum, Berlin. The heads were found in a sculptor's workroom at Akhetaton (Tell el-Amarna). Of unknown parentage, she shared her husband's reforming zeal and in Akhetaton and elsewhere is represented by his side, worshiping the Aton (the sun's disk) in domestic scenes with their infant daughters. There is some evidence that *c.* 1367 B.C. she fell from favour and thereafter lived in retirement. (M. S. DR.)

HIRMER VERLAG, MUNICH

BROWN QUARTZITE HEAD OF QUEEN NEFERTITI FOUND AT TELL EL-AMARNA (ANCIENT AKHETATON) IN 1933. IN THE CAIRO MUSEUM

NEF'I (pseudonym of ÖMER; also known as NEFI OF ERZURUM) (d. 1635) is considered to be one of the leading Turkish classical poets. He was born at Hasankale, near Erzurum. Very little is known about his early life. He was in Istanbul during the first years of the reign of Ahmed I and, after serving as a minor government official, succeeded in gaining the favour of Sultan Murad IV, himself a poet of some distinction. But he made many enemies and, in 1635, one of these, Bayram Pasha, then deputy grand vizier, secured his execution. In his satires, the *Siham-i Kaza* ("Arrows of Fate"), he attacked even the highest public figures, without mercy; sometimes with wit, but often with obscene vulgarity. These works are now interesting mainly as character sketches of the period. Nef'i's *Kasides* (odes), of which editions appeared in 1836 and 1853, are distinguished by considerable dignity of style. They show him to have been a man of vigorous personality and imagination.

See E. J. W. Gibb, *A History of Ottoman Poetry*, iii (1904). (F. I.)

NEGEV (NEGEB), the triangular-shaped southern part of Israel reaching to the Gulf of Aqaba at Elath, is bordered on the west by the United Arab republic (Egypt) and on the east by Jordan. It is traditionally the frontier or desert land south of Beersheba. Its northern limit is undefined but it coincides approximately with that of the Beersheba administrative subdistrict. Its area is about 4,633 sq.mi., *i.e.*, about 60% of Israel; and its population in 1962 was about 100,000 or 5% of the population of the country. There are about 20,000 nomadic Bedouin Arabs.

The northwestern Negev is a low plain covered with desert scrub, sand dunes and gravel. Southeastward the country rises to the central Negev limestone ridges (maximum height exceeding 3,000 ft.). The centre is mainly above 1,000 ft.; eastern Negev slopes to the Ha'arava ('Arabah) rift valley and the Dead sea. The south, centre and east are desolate and rugged and much dissected by wadies which carry torrential streams after the occasional winter storms.

The area has been greatly developed since 1949, and there are numerous experimental agricultural settlements in the north and west. Without irrigation only extensive grazing of camels, goats and sheep is possible. There is considerable mineral wealth. At Sodom (Sedom, Sdom) potash and bromine are produced by evaporation of Dead sea water, and phosphates are mined at Oron. Small quantities of iron ore, copper, manganese, gypsum and kaolin are mined. Beersheba (*q.v.*) is the main town and has industries based on local minerals. Elath is Israel's port on the Red sea and from there a pipeline transports crude oil to the north; both Elath and Dimona are expanding towns. There are good roads from Beersheba to Elath and Sodom, and the railway is being extended south from Beersheba.

The Negev had numerous small frontier and trading posts in Roman and Byzantine times, supported by ingenious systems of water conservation and irrigation. In the Old Testament period it was at times under the control of the kings of Judah (*see* JUDAEA; JUDAH). *See* also ISRAEL; JORDAN.

BIBLIOGRAPHY.—N. Glueck, *Rivers in the Desert: a History of the Negev* (1959); Y. Kedar, "Water and Soil From the Desert, Some Ancient Agricultural Achievements in the Central Negev," *Geogr. J.*, vol. cxxiii, pp. 179–187 (1957); N. Bentwich, "Development in the Negev," *J. Cent. Asian Soc.*, vol. xlv, pp. 176–183 (1958) (C. G. SM.)

NEGLIGENCE is a concept found in all law. As a basis of liability in Anglo-U.S. law, it is set off against intent on the one hand and mischance or accident on the other. It is broadly defined as a failure to take care in view of foreseeable danger. It is determined by the standard of conduct of the ordinarily prudent man under similar circumstances—a question for jury determination unless the conduct in litigation can give rise to only one reasonable inference. In the latter case it is for the judge to draw the inference.

The negligence concept came into great importance early in the 1800s when it became the basis of the negligence action, superseding the earlier actions of trespass *vi et armis* ("with force and arms") and trespass on the case for physical injuries to person and property resulting from unintended hurts. The action arose out of highway horse and buggy collisions but was quickly extended to inland waterway traffic collisions, railway casualties, industrial master and servant cases, and by the end of the century had been extended to landowners with respect to injuries to highway travelers as well as to persons who came upon landowners' premises, to contractors, manufacturers, users of firearms, municipal corporations (especially for defective streets), to physicians, in some instances to charitable hospitals, and practically to all cases of unintended physical injuries to person and property. By statute it had also been extended to injuries resulting in death.

The action is not infrequently employed to recover damages for injuries resulting from defective performance of professional services, as for example those undertaken by lawyers, brokers, accountants, abstracters and the like. But the action in these cases stems from a different source and bears little resemblance to the negligence action for physical injuries.

The displacement of the action of trespass for physical injuries by the negligence action was the most radical revolution in common-law history. It was the courts' response to the Industrial Revolution. Financially weak industry and enterprise, with their dangerous and imperfect machines and processes and numerous untrained and inexperienced employees, could not do business under the strict liability of medieval tort law. The severity of the early law was completely reversed by the negligence action, under which at every point of an extended and complicated formula the burden was placed upon the victim to sustain his case. The defenses available to defendants became so numerous and exacting that they cannot be catalogued in any brief summary. Suffice it to say that the action of negligence became a great favourite of defendants and the more skilled advocates of the profession. Doctrines were spun infinitely in the fashion of religious doctrines, architectural designs, dress, manners, oratory, writing and ornamentation of every sort of that century. Even though a victim might win a jury verdict the chances were that his verdict could not run the gauntlet of appellate review. In brief, through the doctrines of negligence law there was a practical moratorium on legal liability for unintended personal physical injuries for almost three quarters of the 19th century.

Shortly after the middle of the century a reaction set in which has continued to increase in strength. In every area of activity brought under negligence law its doctrines have undergone numer-

ous modifications by court or by statute. Practically the whole area of injuries suffered by industrial employees was brought under workmen's compensation acts in England in 1897 and in the U.S. states in the early 1900s. Numerous immunities once enjoyed by landowners, railroads, charitable institutions, municipal corporations and other governmental divisions, manufacturers, suppliers, contractors, public service companies, physicians and surgeons have fallen by the way. Broad comparative negligence statutes in all the Commonwealth of Nations and in some of the U.S. states and limited statutes in numerous specific instances in most of the states have made inoperative many of the sweeping defenses once available to defendants. Jury trial, especially in England, has either been foregone in negligence cases or greatly modified, thus reducing trial errors once relied on for reversals of trial court judgments. Appellate courts by various doctrinal devices exercise an increasingly stronger hand in the disposition of negligence cases. Modern scientific techniques for making proof of nervous and psychic injuries and for evaluating all injuries to the person have removed much of the guesswork in measuring damages in personal injury cases. Of importance also is the rise of a claimants' bar equal in education and training to offset the advantages so long enjoyed by the superior advocates of corporate clients.

Only in the area of motor vehicle traffic injuries has the negligence action failed to respond to the demands of modern conditions. Here is found the overwhelming mass of negligence litigation. Liability insurance is a factor in nearly every litigation following traffic casualty. In many cases there is no basis of liability; in many others the defenses are so clear that litigation would be futile; many others are settled for a pittance; some are settled equitably; the serious cases as a rule are hard fought with the results utterly unpredictable. Negligence doctrines in these cases, however modified, are too refined for juries and in many instances too complicated for trial and appellate processes. The courthouses of all the larger centres of population are choked with cases and the trial dockets are years in arrears. Much of the time and energies of appellate judges are absorbed in the examination of extended records and briefs and in writing extended doctrinal dissertations or in minute regimentation of factual detail. The negligence law that so largely had its source in the horse and buggy traffic of the 19th century has run its course as a means of litigating the motor vehicle casualties of the 20th, and some better remedy is as urgent here as it was in the industrial injuries of the early part of the century. *See* also TORT; CASUALTY INSURANCE.

NEGOMBO, a coastal town of Western province, Ceylon, 23 mi. N. of Colombo, to which it is connected by rail and road. Pop. (1953) 38,628. Two-thirds of the people are Christians, mainly Roman Catholics. It lies at the entrance to a large, palm-fringed lagoon, and has always been important for its fisheries (crabs and prawns). In Dutch times it was a principal centre for cinnamon, but this, having declined, has been largely replaced by coconuts. Negombo has a fine rest house and some 17th-century Dutch buildings including a gateway (1672). Four miles away is Katunayaka airport, formerly a Royal Air Force base, which was developed commercially in the 1960s. (B. H. F.)

NEGOTIABLE INSTRUMENT, in law, a term employed to describe a number of different instruments or documents, each having most, if not all, attributes of negotiability; *i.e.*, transferability, protection of bona fide purchasers and so on. These include bills of exchange, checks, promissory notes, bonds, debentures, share certificates, bills of lading and warehouse receipts. *See* COMMERCIAL PAPER; INVESTMENT PAPER. (R. T. S.)

NEGRÍN, JUAN (1889–1956), the last republican prime minister of Spain, was born in the Canary Islands. He became a physiologist of repute and held a chair at Madrid university (1923–31). Turning to politics (1929) as a moderate socialist, he was elected to the *Cortes* in 1931, 1933 and 1936. In the civil war, as minister of finance under Largo Caballero from Sept. 1936 to May 1937, he was held to be responsible for sending most of the Bank of Spain's gold reserves to the U.S.S.R. He succeeded Largo Caballero as prime minister in May 1937. In Sept. 1938 he gave orders for the withdrawal of the International brigade, but, with Communist support, he urged resistance even after the collapse of the Catalan front. In March 1939 the setting up of a council of defense in Madrid brought about Negrín's departure and the capital surrendered. He was in exile in Paris until the German occupation, then in Great Britain and the United States. He resigned as head of the government in exile in 1945 after attacks led by Indalecio Prieto. He died in Paris on Nov. 12, 1956. Negrín was accused of subservience to the Soviet Union, but it has been contended that, in the face of the nonintervention policy and the republic's need for arms, he had no alternative. His political pronouncements were liberal and sophisticated in tone.

NEGRI SEMBILAN, a state of Malaya in the Federation of Malaysia (*q.v.*), bounded north by Pahang, south by Malacca, east by Johore and west by Selangor and the Strait of Malacca. Area 2,565 sq.mi.; pop. (1957) 364,524. A loose confederation in the late 18th century, it accepted British protection after 1874 and joined the original Malayan federation in 1895. The state is ruled by a constitutional sultan (Yang di-Pertuan) selected from the territorial chiefs, a system unique among Malay states reflecting its origins as a league of immigrants from areas including central Sumatra and Celebes. It has a short coastline and its indigenous people are spread through the steep-sided valleys around the southern end of Malaya's central range which breaks down into discontinuous mountains, creating a landscape like the Italian lakes except that the valley bottoms are under paddy.

Malays form 42% of the population, Chinese 41% and Indians 15%. In all the townships Chinese and Indians predominate. Seremban (pop. [1957] 52,091), the state capital, controls the road network, and completely overshadows Kuala Pilah (12,024), an old political centre east of the hills and now little more than a local market town. Negri Sembilan has had prolonged external associations because it borders Malacca, the source of its first modern economic impulses, with which it had rail connections until 1942. Port Dickson, midway along the coastline, was an experiment in port development which failed. With a population of 16,609 it is now used as a holiday resort and only on a small scale as a port. Nineteen new villages were created between 1948 and 1952 in an attempt to isolate Chinese farmers from guerillas in the jungle war, which was more bitter in the east of this state than in most other parts of Malaya; these farmers total nearly 20,000 (92% Chinese).

Negri Sembilan has a complex economy. Along some western valleys and toward the coast are a few declining alluvial tin mines, yielding barely 1,000 tons of tin concentrates annually. It has more than 200,000 ac. of rubber, equally divided among estates and smallholdings and producing 40,000 tons annually, and about 30,000 ac. under paddy. There is a higher proportion of roads and railways than in any other Malay state, and the state contains part of the road network of the west coast "tin and rubber belt," one of Malaya's two east-west roads and the junction of the railway lines on either side of the mountains, at Gemas (7,000). Non-Malays have largely caused the displacement of the indigenous rice-growing economy. (E. H. G. D.)

NEGRITO (Span. for "little Negro"), the name originally given by Spaniards to some aboriginal groups of the Philippine Islands but now applied also to a hypothetical element of the population of southeast Asia, Indonesia, New Guinea and other parts of Melanesia, Australia and Africa. This element is said to be represented in purest form by the Andamanese (*see* ANDAMAN ISLANDS) and in various degrees of admixture by the Aeta (*q.v.*) of the northernmost part of Luzon in the Philippines, the Semang (*q.v.*) of the Malay peninsula, the Tapiro, Aiome, Ekari and other tribes of the central New Guinea mountains and by the African pygmies (*see* PYGMY). On the basis of geographical distribution and certain physical differences these pygmy groups

have been referred to as Negrillo (Africa) and Negrito (Asia and Oceania).

Negritos are characterized by short stature, dark-brown to black woolly hair, yellowish-brown to black skin; nose shape varies from broad and flat to straight and moderately broad with the tip directed upwards. Lips generally are thick, the upper lip tending to be deep and convex; eyes are often large and prominent and the face is short; body and facial hair is scanty. Skulls may be brachycephalic or mesocephalic but dolichocephalic types occur in Africa and New Guinea. Height ranges from about 1.36 m. (54 in.) among pygmies of the equatorial forests of Africa to about 1.52 m. (60 in.) among the Semang and the Ekari. Some groups practise horticulture, while others live by hunting and food-gathering, using the bow as a main weapon. They also make effective use of simple stone axes.

Differences of opinion exist as to the origin of the Negritos and their relationship to other peoples. One view is that the Negritos were early inhabitants of Asia who were driven by later-evolved hordes to Africa, southeast Asia, and to the Pacific area, where they represent one of the major genetic components among Australian aborigines and other Oceanic peoples. But it has also been held that there are no close links among pygmy groups from different parts of the world, and much evidence supports the view that pygmies in some areas at least are modified representatives of the local general populace.

Studies of blood group gene frequencies and data for the sickle-cell trait in various Negrito groups have shed new light on these theories. The sickle-cell trait, a gene marker common among African peoples and associated with sickle-cell anemia (*see* ANEMIA), has not been found in the Pacific peoples; this is regarded as evidence that African pygmies do not share Negrito elements with Asian and Oceanic Negritos. The extensive data now available on blood-group gene frequencies make it appear unlikely that African, Asian and Oceanic pygmy groups are related. Blood studies indicate that Papuan pygmies or Negritos differ widely from pygmy groups in other parts of the world, but that they are closely akin to neighbouring Papuans. Similar relationships have been found for other Negrito populations and their taller neighbours.

NEGRO, a member of a group of human populations either derived from or autochthonous to Africa south of the Sahara (excluding groups recently migrated from Europe or Asia). The derivation of the word is from the Latin *niger* ("black") but its use as denoting a particular subgroup of mankind comes from the Spanish-Portuguese term *negro* ("dark") dating from the time of the African slave trade.

In the United States the substantial Negro population represents a migration from Africa during historical times. Biologically it differs from its African ancestral groups by an important hybridization with the local white population. The white genetic component among U.S. Negroes has been evaluated as approximately one third (*see* NEGRO, AMERICAN).

Characteristics and Distribution.—The general characteristics of Negro populations are: a dark skin, woolly hair, thick lips and a very high frequency of the cDe (Ro) blood group (*see* BLOOD GROUPS). Most of these populations are characterized by a short and broad nose, a protruding lower part of the jaw (prognathism) and legs that are long compared with the trunk. The dark skin is not confined to Negroes; it also exists in quite different human stocks in Australia and India, and seems to result from an evolution of the gene pool in a warm and sunny climate.

Adaptive selection seems to be one of the most important differentiating factors within the group of Negro populations. Those living in the prairie and savanna zone extending between the Sahara and the equatorial forest (the so-called Sudanese zone) are tall and slender, of very dark skin with little body hair. Such are, for example, the Wolof and Hausa (*q.v.*) of west Africa. These characteristics are, however, most marked in the Nilotic populations living in the marshes and grasslands around the junction of the Nile and Bahr-el-Ghazal rivers (*see* NILOTES). The inhabitants of the equatorial forest, on the other hand, are short, of lighter skin, with more body hair. These features are extreme in the pygmies who, from strong evidence, seem to have lived much longer in the forest than the other forest Negroes. The pygmies are very short (averaging 1.444 m. or 56.9 in. for the Bambuti [*q.v.*] of the Ituri forest), with stocky bodies, large heads and relatively short legs; the face is low with a large mouth under a very broad nose (*see* PYGMY).

Apart from the pygmies, there are two distinct groups of African populations. The first one, comprising the Bushmen and the Hottentots, is called Khoisan (*q.v.*). The difference between Bushmen and Hottentots is mainly that Bushmen are shorter (averaging 1.52 m. or 59.8 in.). They are confined to the Kalahari desert in south Africa. Their yellowish-brown skin tends to be much lighter than in other Africans. The hair is so tightly curled that it forms little individual spirals (peppercorn hair), leaving much scalp exposed (*see* HAIR). The skull is five-cornered and the face is flat and small with wide and prominent cheekbones. The eyelid gap is narrow; the nose is broad and the lips full. Several of these characteristics give the Khoisan a mongoloid appearance, but this correspondence seems to be merely fortuitous. Women among the Hottentots (and to some extent the Bushmen) display steatopygia, an accumulation of fat in the buttocks which gives a pronounced protrusion (*see* BUSHMAN; HOTTENTOT).

The second group, often called the Hamitic group, comprises different populations of east Africa (for example, the Tutsi of the Rwanda area, the Hima of Uganda, the Masai of Kenya, the Somali); linguistically it includes some Hamites, Nilotes, Nilo-Hamites and even Bantu. They are tall and slender, with all vertical dimensions emphasized—long narrow faces, noses and skulls, long arms and legs. The skin is very dark, the hair is woolly or curly. The orthognathous (square-jawed) face with its narrow nose contrasts with that of the classical Negro type. (*See* HAMITE; NILO-HAMITES; BANTU LANGUAGES.)

Natural History.—The differences between the Khoisan and other Africans are so great that some authors do not consider the Khoisan as Negroes but as another major differentiation within modern mankind. But if, as many anthropologists believe, the Khoisan derive from the Negro trunk, they must have parted from it a long time ago when it was still generalized, before the differentiation of the other types. There is strong evidence that several fossil men of normal stature found in south Africa are ancestral to the Bushmen; *e.g.*, the Boskop skull (*q.v.*), which supposedly dates from the middle Stone Age.

The area occupied by the Khoisan was much larger in the past than today; it covered at least the whole of southern Africa and a part of east Africa. They were forced southward by the waves of migration of Bantu-speaking tribes; such a move was still going on at the time of the arrival of Europeans in south Africa; the final confinement of the Bushmen to the Kalahari desert occurred during historical times.

Some objections have also been raised against the inclusion of the Hamitic group in the Negro subdivision of mankind. The association of a black skin and long legs on one hand, and orthognathous face and narrow nose on the other, has led several authors to consider the Hamitic peoples as having resulted from an ancient Negro-white mixture. They are, however, very different from mulattoes and it appears more reasonable to attribute their fea-

tures merely to a long independent evolution from some generalized stock. Archaeological data show them as established in Kenya long before the arrival of the typical Negroes. Their morphology suggests a hot, sunny and dry country of origin.

The homeland of the typical Negroes (the sub-Saharan Africans with the exception of the Khoisan and the Hamitic group) probably lies in a strip of country south of the Sahara, between the Atlantic coast and the Nile. Excepting the pygmies, the expansion of the typical Negroes toward southern and eastern Africa is relatively recent. The most spectacular known phase of this expansion is that of the Bantu-speaking tribes who, starting approximately 4,000 years ago from a restricted area in west Africa, invaded most of central, east and south Africa and probably would have reached the Cape of Good Hope if they had not been stopped by the Europeans already settled in south Africa.

If independent evolution of an isolated group is one of the main factors of differentiation of the Negro populations, hybridization between different groups coming into contact is another; it has occurred in many places and at several times. The influence of white elements from Arabia is clear in the Horn of Africa. An Indonesian migration reached Madagascar and mingled in various proportions with the local Negroes, the Negro component being discrete or absent in the most aristocratic class. The Hamitic peoples were great travelers; the Fulani (*q.v.*) of west Africa display an important Hamitic component; the Hamitic influence is clear also in the physical appearance of many Bantu-speaking tribes with whom they are in contact (in the Lake Victoria area, for example) or with whom they have been in contact in the past (several tribes of south Africa, for example); such contact has possibly influenced the physique of the Nilotic populations. Conversely, the Hamitic peoples are hybridized to a certain extent by their neighbours. Hybridization also occurs in the equatorial forest between pygmies and normal-statured Negroes.

Another factor of differentiation lies in mutations (changes in genes to induce new hereditary features). A typical example is the sickle-cell trait, a hereditary abnormality of the hemoglobin, giving to the red blood cells a sicklelike shape when deprived of oxygen. The feature seems to have arisen by mutation in the Negro stock; its frequency varies much from one African population to the other and seems to depend on the severity of malaria in earlier generations, since those who carry one sickle-cell gene have a relative immunity to malaria. This advantage for the population is counterbalanced by the fact that the (homozygous) presence of two such genes kills the affected child. The sickle-cell gene has somewhat diffused outside Africa; frequent in the American Negroes, it is also found in some malarial districts of Greece and Italy, where its introduction needed only a very minute Negro admixture. It is also present in southern Arabia and in a few tribes of India (where its significance is more hypothetical) and was even interpreted by some authors as an indication of an Indian component in the Africans (*see* ANEMIA).

Negritos and Melanesians.—Several small groups of people (*see* NEGRITO) apparently similar to the African pygmies live in different places in Asia. New Guinea and other Melanesian islands are inhabited by populations with a negroid appearance (Melanesians). Whether these Melanesian and Negrito populations are related to the African Negroes is not established with certainty; in particular, they lack the typical high Ro frequency of the Africans. If such a relation were proved, the problem of the origin and diffusion of the Negroes would be much more complicated than indicated by the scheme given above.

See RACES OF MANKIND; AFRICA: *Ethnography* (*Anthropology*); *see* also references under "Negro" in the Index.

BIBLIOGRAPHY.—Works on physical traits of Negroes are in general restricted to articles in scholarly journals; a summary will be found in G. Lefrou, *Le Noir d'Afrique* (1943). An excellent general book on the story of human evolution is W. W. Howells, *Mankind in the Making* (1959). For Hottentot and Bushman physical traits *see* I. Schapera, *The Khoisan Peoples of South Africa: Bushmen and Hottentots* (1952). On the physical characteristics of Negroes in the United States, *see* M. J. Herskovits, *The American Negro* (1928). *See* also R. Biasutti, *Le razze e i popoli della terra* (1959); W. S. Pollitzer, "Hemoglobins, Haptoglobins, and Transferrins in Man," *American Anthropologist*, vol. 65 (1963).

(J. R. HI.)

NEGRO, AMERICAN. In the United States a person is popularly regarded as a Negro if he possesses any Negro ancestry, regardless of the number of white or Indian ancestors he may also possess. In states concerned with the problem of race, identification of a Negro by physical appearance or by reputation has been insufficient, and the law has defined a Negro with considerable precision. For example, the Virginia law of 1930 defined a Negro as any person in whom there is ascertainable any quantum whatever of Negro blood. That the concept of who constituted a Negro was not by any means unchanging is attested by the fact that in 1910 Virginia changed its definition of a Negro from a person with one-fourth Negro blood to one with one-sixteenth Negro blood and then to its definition of 1930. The problem of the definition of a Negro began early in the American colonial period. The social and legal status of the children resulting from the union of whites and Negroes, usually illegal and outside the marriage bonds, was frequently open to question. They were usually defined as Negroes regardless of the amount of white blood; and they were defined as slaves if their mothers were slaves. Efforts to control miscegenation by law were notably unsuccessful during the slave period, and although many states had laws against intermarriage in the second half of the 20th century, miscegenation persisted. The loosely defined mulatto element, the product of unions of Negroes and mulattoes as well as of whites and Negroes, continued to provide the legally defined Negro element with a range of physical types that defied any precise, scientific classification.

After a survey of the growth of the Negro population in the United States this article is organized according to the following outline:

Population.—At the time of the first decennial census in 1790 the 757,208 Negroes in the United States constituted approximately one-fifth of the total population. More than 90% of them were concentrated in the south, but within that region there were great variations in the proportions of Negroes to the white population, because of the concentration of the Negro population in the areas of the plantation economy. By 1860 the Negro population had increased to 4,441,830 and was about one-seventh of the total population. With the spread of the plantation, there was a significant shift of the Negro population to the states of the southwest, notably Alabama, Mississippi and Louisiana. The increase continued in the years following emancipation, the figure having reached 8,833,994 by 1900 and 11,891,143 by 1930. When the Negro population reached 18,871,831 in the census of 1960, it constituted 10.5% of the total population.

One of the most remarkable facts about the Negro population in the 20th century was the movement of large numbers to urban communities in the south and out of the southern states altogether. Although the movement was rather steady, it was greatly accelerated during World Wars I and II, and during the 1950s and early

1960s. The 1940s saw the Negro population increase by 44.2% in the northeast, 50.2% in the north central states and 237.4% in the west. During the next decade the increase was 50.6% in the northeast, 54.7% in the north central states and 89.3% in the west. As late as 1920 the proportion of Negroes living in the south was 85%, but by 1950 it was approximately 68% and in 1960, 60%. In 1910 no city in the nation had as many as 100,000 Negroes, but in 1950 there were 14 such cities, and in 1960 there were 24: Atlanta, Baltimore, Birmingham, Chicago, Cincinnati, Cleveland, Dallas, Detroit, Houston, Kansas City, Los Angeles, Memphis, Miami, Mobile, Newark, New Orleans, New York, Norfolk-Portsmouth, Philadelphia, Pittsburgh, Richmond, St. Louis, San Francisco-Oakland and Washington.

These shifts in the Negro population materially affected the relationships between the southern white population and the Negroes. The steady urbanization of the Negro population also had considerable economic, political and social consequences for the group as a whole. The migration of Negroes to the cities of the south, north and west widened the range of economic opportunities for Negroes, but it also created new racial tensions in numerous social and economic areas. The greater opportunities for Negroes to vote in northern communities noticeably increased their political power by giving more of them an opportunity not only to hold public office but also to affect the outcome of close elections.

At the beginning of the 20th century there was some thought that the Negro problem would solve itself by the gradual disappearance of the Negro as a racial group. The growth of the Negro population in the first half of the century, however, and the vigour of its participation in American life while retaining its separate identity seemed to indicate that this was not likely to occur. The Negro must be accepted as a permanent part of the body politic, and his status must be considered within the framework of the American social order.

I. THE SLAVE PERIOD

As explorers and servants with the Spanish and Portuguese, Negroes were in the new world by the early 16th century. In the beginning the European settlers gave no serious consideration to the use of Negroes to solve the problem of the acute labour shortage, but the idea eventually took hold. Their easy identification because of colour, combined with the apparently inexhaustible supply of Negroes and their non-Christian background, convinced the enterprising settlers that Negroes would be the ideal permanent workers in the task of developing the new world. Although the precedent for Negro slavery in America had been established by the Spanish and Portuguese, the English were slow to adopt the practice.

The first Negroes that landed at Jamestown in 1619 were actually indentured servants; and even after slavery was legally established in the English colonies the Negro population grew slowly. At the end of the first century there were fewer than 25,000 Negroes in Virginia, while Maryland had approximately 40,000 a century after the settlement of that colony. In the New England and middle colonies the Negro population was much smaller, with 5,000 in Massachusetts and 19,800 in New York at the time of the American Revolution.

Proposals for the abolition of slavery began in the late 17th century and increased in number before and during the American Revolution in both north and south. The Northwest Ordinance of 1787 forbade slavery in the territory northwest of the Ohio river. On the other hand the federal constitution recognized the existence of slavery by providing that three-fifths of the slaves would be counted when determining the apportionment of representatives and direct taxes among the states. The constitution also provided that the importation of slaves should not be forbidden before the year 1808.

The significant increase in the number of Negroes began with the demand for cheap raw materials, primarily cotton, created by the Industrial Revolution. The discovery of the short staple variety of cotton made possible the cultivation of the crop in a much larger area of the southern United States than had hitherto been possible, and the invention of the cotton gin (1793) made practicable the extensive cultivation and processing of the raw material for the factories of England and other countries. Within a generation, the vast area that came to be known as the cotton kingdom was settled and developed; and the Negro population began to shift from the upper south to the southwest and to increase enormously, thanks to smuggling of Negroes from the Caribbean and Africa and to the encouragement given to slaves to increase their own population. This was achieved, in part, by deliberate slave breeding.

Opposition to proposals for the abolition of slavery increased in the south; justification of the region's "peculiar institution" prevailed. Southern apologists turned to the Bible and to the history of ancient Greece to find authority for slavery. As antislavery criticisms by northerners grew in intensity, southern spokesmen heatedly defended the plantation system and contended that slavery was indispensable to it. They buttressed their arguments with assertions that the Negro was innately inferior to the white man and incapable of rising above a servile status.

Slaveholding in the United States was always confined to a small segment of the population. Only 384,000 southerners, out of a population of more than 8,000,000, held the 3,900,000 Negroes who were in slavery in 1860. Most owners, moreover, had small numbers of slaves. Approximately 330,000 held fewer than 20 slaves, while more than 200,000 had 5 slaves or less. At the same time only 1,700 owners held as many as 100 slaves. By 1860 the price of slaves was prohibitive for all but the most affluent; the cost of a prime field hand—a healthy male between 16 and 25 years of age—had risen to $1,800 on the New Orleans market.

Because the owner had to be protected in his property and because the community had to be protected from the possibility of violence at the hands of slaves, a great body of laws commonly known as the slave codes grew up in each of the slave states. There were considerable variations, to be sure, but certain provisions were to be found in all of them. Slaves could not be away from the premises of their owner without written permission; they were incompetent to make contracts and their testimony was inadmissible in any litigation involving a white person; they could not own property; they could not be taught to read or write; and they could not assemble together unless a white person was present. These laws were not always strictly enforced, but whenever there was fear that the slaves might become ungovernable, the enforcement machinery of the state was alerted and, for a while, the laws were carefully observed.

Whether they were on a cotton, rice or sugar plantation or in urban communities (where approximately 500,000 were living by 1860), the slaves' principal duty was to provide income and comfort for the owners. Field hands, working in gangs or on task assignments, laboured for long hours in the cultivation and harvesting of the crops. House servants, tending to be more numerous than the owner actually needed, performed a variety of chores. Town slaves were engaged in many tasks which required considerable skills, as indeed were some of the plantation slaves. Geared as it was to the making of profits the slave economy was constantly in search of ways to cut production costs. Thus, only the barest essentials for the subsistence of the slaves were provided. Food was simple, though adequate in quantity; clothing was made of the cheapest materials or, as was frequently the case for house servants, was discarded attire of the owner and his family; and housing consisted of crude huts that barely protected the slaves from the weather.

The majority of the slaves accepted their degraded lot with no outward manifestation of dissatisfaction. Some, however, such as Gabriel Prosser in 1800, Denmark Vesey in 1822 and Nat Turner in 1831, planned or executed revolts that terrorized the white population for miles around. Others registered their resentment by destroying farm implements or animals or, occasionally, by murdering their owners. Many more ran away, either by means of the Underground Railroad (*q.v.*) with the help of abolitionists or by means ingeniously devised by themselves. Those who remained in bondage secured some satisfaction through improvising the spirituals that became a significant contribution to American culture, or embracing the religion of their owners, or through recrea-

tional activities provided by social intercourse with other slaves or with free Negroes.

In 1860 approximately half of the 488,000 free Negroes lived in the slave states, where they were subjected to proscriptive laws hardly less severe than those in the slave codes. Their contact with slaves was especially frowned upon lest they contaminate them with ideas of freedom, while in the economic sphere they were carefully circumscribed, lest their activities work a serious hardship on their white competitors. In the north they were concentrated in such cities as Cincinnati, Philadelphia, New York and Boston, where hostility to them often resulted in riots such as those in Philadelphia in 1834 and in New York city in 1839. From the early colonial period, however, they enjoyed some educational opportunities in the north and some freedom to organize social and religious institutions of their own.

Before the Civil War many individual Negroes had made significant impressions upon American life because of their personal accomplishments. Phillis Wheatley and George Moses Horton wrote poetry that was widely read and praised. Benjamin Banneker, an able mathematician, published a series of almanacs and assisted in laying out the city of Washington, D.C. John B. Russwurm graduated from Bowdoin college, Brunswick, Me., in 1826 and in the following year founded, with Samuel Cornish, *Freedom's Journal*, the first Negro newspaper. David Walker became the first militant Negro abolitionist with the publication of his *Appeal* in 1829. He was followed by a large number of Negroes who vigorously fought slavery, including Frederick Douglass, who edited his own newspaper and traveled extensively in the United States and abroad; William Wells Brown, the author of several books and a lecturer for the Western New York Anti-slavery society; and Harriet Tubman, who is credited with having guided more than 300 slaves to freedom.

FREDERICK DOUGLASS

Among the Negro organizations that sprang up before the Civil War the Negro church was, perhaps, the most important. Some local Baptist groups were organized during the American Revolution in Savannah, Ga., and Petersburg and Richmond, Va. In Philadelphia, Pa., Richard Allen and others founded the African Methodist Episcopal Church in 1794, while in New York city, two years later, James Varick and his associates founded the African Methodist Episcopal Zion Church. Fraternal organizations made their appeal to Negroes through the Masons, organized by Prince Hall in 1784, and through numerous local groups such as the Boston African society, organized in 1796. Beginning in 1830 Negroes held national conventions almost annually in which they sought to make known their grievances and to plan for the future. By the time of the Civil War this typically American institution had become a most effective means of articulating the aspirations as well as the accomplishments of Negroes in American life.

II. ECONOMIC LIFE

1. Agriculture.—The vast majority of the almost 4,000,000 slaves were field hands and domestic servants. The failure of the federal government to provide "forty acres and a mule" for most of the freedmen and prohibitions of some southern states against land-owning by freedmen kept most of them agricultural workers. In 1900, 192,993 Negroes owned farms, of which 54,017 were encumbered. Three-fourths of the Negroes living on farms were tenants who paid rent or sharecroppers who received a portion of the sale of the crop. Most of them, but particularly the sharecroppers, were compelled to obtain advances from the country merchants for food, clothing, tools, farm implements, etc., at an increase in price from 40% to 100%. Since the value of the crops was sometimes less than the advances and since the books were kept by the merchants, many tenant farmers and croppers started the new year in debt. At the beginning of the 20th century, in some parts of the south, nine-tenths of all farmers fell into debt.

In 1920, the last census year before the depression set in, there were 700,439 Negro tenant farmers. Of these, 333,026 or 47.5% were sharecroppers. Negro farmers operated 40,884,199 ac., or 12% of all the farm land in the south. The various measures of the New Deal to provide relief for farmers did not benefit Negroes as much as they did whites. In 1940 the number and percentage of Negro farm owners were about the same as in 1900. On the other hand, the percentage of tenants among farm operators remained about the same and the proportion of croppers among tenants increased.

In the period from 1940 to the early 1960s the number of Negroes engaged in agriculture in the South declined. The revolution in agriculture required technical skills which few Negro tenants and sharecroppers possessed. Moreover, like other farm workers, many Negroes were attracted to the newly industrialized southern cities. They sought better opportunities for employment and education, improved living conditions and fuller protection of the law. These better conditions, together with larger enjoyment of civil rights, impelled many Negroes to continue migrating to the north.

2. Domestic and Personal Service.—Of the total number of employed Negroes, the proportion of those in domestic and personal service increased from 21.6% in 1910 to a little over 30% in 1940 while the proportion of white workers in these fields remained fairly constant. Between 1940 and 1960 the proportion of private household servants decreased by 26.6% among whites and 6.3% among nonwhites (mainly Negroes). On the other hand, during the same period the proportion of workers in other personal service fields—beauticians, barbers, cooks, counter clerks and waitresses—increased by 61.4% among whites and 101.2% among nonwhites. These statistics suggest that new opportunities in personal service, clerical, sales and kindred occupations enabled workers of both races to leave domestic service and that the change was greater among Negroes than among whites.

3. Industrial Workers.—After slavery was abolished many of the Negroes who had held skilled jobs lost them to white workers. Moreover, barbering, waiting, etc., formerly known as "Negro jobs," increasingly attracted large numbers of white workers. This displacement and the reluctance to accept Negroes in the new mechanical industries in the south spurred some migration to the north and the west but there whites also began to take "Negro jobs." The rapidly expanding industries in the north preferred European immigrants to Negroes, both as skilled and as unskilled workers. The American Federation of Labor (A.F. of L.) denied membership to most of the few skilled Negro workers or it organized them in separate unions, thus pitting Negro and white workers against each other. The fact that Negroes were first brought into some industries as strikebreakers increased racial antipathy in the ranks of labour. The Knights of Labor in the latter part of the 19th century and the Industrial Workers of the World in the early part of the 20th century, both of which included a considerable number of Negro workers, disappeared, largely because these organizations were considered revolutionary. (*See* also LABOUR [TRADE] UNION.)

The first opportunity for Negroes to enter northern industry in force came during World War I. The acute need for labour, resulting from the departure of many white workers for military service and the virtual cessation of immigration, brought new jobs in iron and steel mills, coal mines and automobile factories to substantial numbers of Negroes, many of them from the south. Proving to be, on the whole, efficient workers, they fortified their position during the 1920s. During the depression of the 1930s, however, they were "the last to be hired and the first to be fired."

Their plight was ameliorated by the emergence in 1935 of the Congress of Industrial Organizations (C.I.O.) which, unlike the A.F. of L., organized skilled, semiskilled and unskilled workers in an entire industry. The growing increase in the membership of the C.I.O. led the A.F. of L. perforce to liberalize its membership policies; the number of Negro union members soon reached more than

EBONY MAGAZINE

A. PHILIP RANDOLPH

2,000,000. In 1955 these two major trade union federations merged; one of their chief objectives was to double their membership of 15,000,000. The attainment of this objective would necessitate the inclusion of more Negro workers. The merged unions, unlike the two components, for the first time elected two Negroes to the executive council. A notable Negro union official was A. Philip Randolph, president of the Brotherhood of Sleeping Car Porters. He became a vice-president of the A.F.L.-C.I.O. and was an influential leader in other Negro organizations. Opposition to unionization of Negroes continued in the south as part of the reaction against the supreme court decisions of 1954 and 1955 that invalidated segregation in the public schools. An additional problem that came to the forefront in the 1960s was the prediction that the displacement of manpower by automation would bear most heavily on Negro workers.

In June 1941 a group of Negroes proposed to march on Washington, D.C., for the purpose of obtaining governmental action to reduce the widespread discrimination against Negroes in the rapidly expanding war industries. On June 25 Pres. Franklin D. Roosevelt issued an executive order declaring that there should be no discrimination in the employment of workers in defense industries or government because of race, creed, colour or national origin. All contracting agencies of the federal government were to include in defense contracts a provision obligating the contractor not to discriminate against workers for those reasons. The order established a Committee on Fair Employment Practice (F.E.P.C.) to receive and investigate complaints in violation of the order. Although the order met widespread opposition in the south, it resulted in considerable gains in the north. The work of the committee ended in June 1946 when congress failed to appropriate the necessary funds for the ensuing year. Pres. Dwight D. Eisenhower by an executive order dated Aug. 13, 1953, appointed a committee to make recommendations to the government contracting agencies for improving and making more effective the nondiscrimination provisions of government contracts. The order also required the head of each contracting agency to take appropriate procedures to carry out the responsibility of obtaining compliance with the nondiscrimination agreement entered into by government contracting agencies. One of the members of the committee was a Negro. President Eisenhower also called in 1955 a conference of representatives of about 50 of the largest firms in the United States to discuss means of extending nondiscrimination in employment. In some instances contractors encountered difficulties because many trade unions refused to refer Negroes for skilled jobs. Negroes contended that the lack of skilled Negroes was due largely to the fact that many trade unions refused to permit Negroes to become apprentices.

President Eisenhower by an executive order dated Jan. 18, 1955, created the President's Committee on Government Employment Policy to assist the federal agencies in developing a policy to prevent discrimination on the basis of race, colour, religion or national origin in the hiring, promotion, and discharge of federal civilian employees. It served as a review board on complaints of discrimination and rendered advisory opinions to the agencies for corrective action. About 85% of the complainants were Negroes. Despite local community attitudes, especially in the south, the committee reported in 1959 that it had made progress. In 1958 a Negro became chairman of the committee. Pres. John F. Kennedy on March 6, 1961, issued an executive order establishing the President's Committee on Equal Employment Opportunity. This abolished President Eisenhower's two committees and centralized in one committee the responsibility for effectuating a policy to eliminate discrimination in employment by the federal government, by government contractors and by labour organizations.

While congress during the 1950s failed to pass an F.E.P.C. law to prevent racial discrimination in industries, about 18 states and 30 cities enacted "little" F.E.P.C. laws and ordinances. In New York state, which adopted the first of these laws on March 12, 1945, violation of the law was punishable by imprisonment for not more than a year or a fine of not more than $500, or both. In those states which carried similar punitive provisions, Negroes obtained more and better jobs. But most of the laws and ordinances provided only for consultation and recommendation.

The National Urban league, founded in 1910, sought to organize effective community interest toward the solution of community problems resulting from inequality in employment, education and training for jobs, and family welfare. Its commerce and industry council included officers of some of the largest business corporations; and its trade union committee included representatives of many of the most powerful trade unions. It received support also from such organizations as the National Conference of Christians and Jews. Working in co-operation with the various presidential committees formed to combat discrimination in employment, it helped a growing number of Negroes to obtain better jobs.

4. Professional and Business Men.—The number of Negroes engaged in professional, technical and kindred services increased from approximately 192,000 in 1950 to approximately 352,000 in 1960. In the latter year teachers constituted about 47% of the total; clergymen about 5%; doctors and dentists together less than 4% and social workers about 4%. They depended almost entirely on a Negro clientele. Especially after World War II large white firms employed a few Negro architects, engineers, scientists, buyers, sales and public relations representatives and a smaller number in middle-management and executive positions. Negro insurance companies and banks, which had firmly established themselves in the first half of the 20th century, accelerated their growth. In spite of the unfavourable position of the Negro worker in industry and agriculture, and the comparatively small number of Negroes in the professions and in business, the total annual income of all Negroes in the 1960s was approximately $20,000,000,000.

5. Housing.—Housing had always constituted a problem for urban Negroes. The flood of migration away from the south in the first half of the 20th century brought to northern cities over 2,000,000 Negroes, in addition to many white migrants from the south. The newcomers crowded into slums where low-income white and Negro families were already living. Upper-class and middle-class whites fled from the cities to the suburbs and to farms. Blighted urban areas were razed and modern apartments, both private and public, with high rentals, were constructed. The former occupants of these areas swarmed into new ghettos where juvenile delinquency, illegitimacy, dropping out of school, and other social ills were aggravated. Unemployment was rife; a disproportionately large number of Negroes were on the relief rolls. Frustration and rejection by the community bred apathy, bitterness and even criminality. In New York city especially, the influx of Puerto Ricans complicated the problems, as did the large number of Mexicans in Houston, Dallas and Los Angeles.

The first federal conference that studied housing as a national problem was called by Pres. Herbert Hoover in Dec. 1931. Of the eleven volumes of its findings and recommendations, one was devoted to the problems of housing for Negroes. Federal housing policy had been focused on facilitating credit and relieving economic conditions until the Public Works administration and later the U.S. Housing authority provided housing for the underprivileged at rents they could afford. In 1942, the National Housing agency announced a basic policy of "no discrimination . . . on account of race, creed, color, or national origin." This was not an antisegregation policy but a policy aimed at assuring equitable shares for Negroes in housing as it became available. A semblance of an equitable share of low-rent housing was secured for Negroes, although principally on a segregated basis. In governmental-built wartime housing developments, Negroes received almost six times as many units as were provided for Negro occupancy under the larger Federal Housing authority (FHA) program of privately built wartime housing—84,000 as compared with 15,000 units.

Even so, the federal housing policy really sanctioned segregation by leaving its determination to the jurisdiction of local public housing authorities. The first real change came as a result of a 1948 decision of the U.S. supreme court which stated that restrictive covenants (agreements by property owners not to sell to Negroes) could not be enforced in state courts. In Dec. 1949 the FHA ruled that it would not provide mortgage insurance for property on which restrictive covenants were recorded. In 1954 the FHA took steps to encourage the development of demonstration open-occupancy projects, but little progress was made during the rest of the decade. Sen. John F. Kennedy in his 1960 campaign speeches announced his opposition to the use of federal funds for segregated housing and expressed his conviction that such use could be abolished "by a stroke of the pen." After taking office he appointed a Negro, Robert C. Weaver, an authority on housing and a staunch supporter of open occupancy, as administrator of the Housing and Home Finance agency. On Nov. 20, 1962, President Kennedy issued an executive order forbidding discrimination in housing built under loans or mortgages insured by the FHA and the Veterans Administration. The order also included low-rent public housing, housing in urban renewal projects subsidized by the federal government, and housing built with federal loans (such as homes for the elderly, community facilities and college dormitories). Since the order was not applicable to conventional home financing through banks and savings and loan associations whose deposits are federally insured, it did not cover most of the new housing in the nation. Thus, while the federal government's housing policy had progressed somewhat toward the goal of "a decent home and a suitable living environment for every American family," segregation in housing still remained the rule rather than the exception.

III. POLITICAL HISTORY

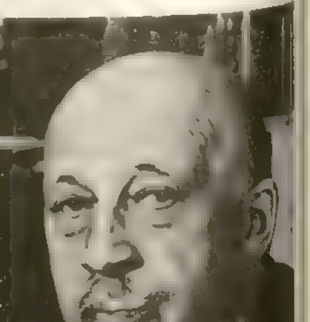
1. From the Civil War to 1900.—The political and civil rights of Negroes have been determined primarily by conflicts between the federal government and state governments. Since about nine-tenths of Negroes lived in southern states until 1900 and about two-thirds in the 1960s, most of the issues involved the federal government and these states. The conflict began immediately after the Civil War. The 13th amendment, effective as of Dec. 18, 1865, abolished slavery and involuntary servitude. But the southern states in 1866 adopted new "black codes" that sought to keep the freedmen close to their former servile status. Congress was dominated by radical Republicans who had inherited the abolitionist tradition and by other Republicans who wanted to maintain political control of the south and the north's economic superiority established during the Civil War. In 1866 congress adopted a Civil Rights act which declared that Negroes were citizens of the United States and were entitled to equal treatment before the law. The "Great Reconstruction acts" in 1867 provided for the establishment of state constitutional conventions in the former confederate states, with the requirements that Negroes should be eligible to vote for members and to be elected as members. A further requirement was that the new constitutions drafted by these conventions should grant to Negroes the right to vote. Plebiscites, in which one requirement was that Negroes should vote, approved the proposed constitutions, thus giving state sanction to the federal grant of franchise.

The 14th amendment was adopted by congress, ratified by three-fourths of the states and declared in effect as of July 28, 1868. Its first section strengthened the Civil Rights act by making Negroes citizens of the states in which they resided and also citizens of the United States. No state was to take any action that would violate the rights that this section sought to protect. The second section gave each state the choice between granting suffrage to adult male citizens and suffering a reduction in its representation in the house of representatives and in the electoral college proportionate to the number denied the right to vote. Congress was given the right to enforce this amendment. The state legislatures, elected after the approval of the new constitutions, were required to ratify the 14th amendment before the states could be restored to the Union. The 15th amendment, declared in effect on March 30, 1870, stated that the right of citizens of the United States to vote should not be denied or abridged by the United States or by any state on account of race, colour, or previous condition of servitude and that congress was given the power to enforce this amendment. The enforcement acts of 1870 and 1871 sought to protect Negroes from armed attacks. Finally, the Civil Rights act of 1875 prohibited individuals from discriminating against Negroes in public places and on public carriers.

During the period of Reconstruction, 1866–77, southern Negroes were elected as members of the U.S. house of representatives, the U.S. senate and some state legislatures. In Feb. 1870 Hiram R. Revels of Mississippi took the senate seat formerly occupied by Jefferson Davis. Four years later another Negro, Blanche K. Bruce, was elected to the U.S. senate from Mississippi. A few Negroes also served as high-ranking state officials. After the organization of the Ku Klux Klan in 1866, however, southern whites used force, intimidation and fraud to prevent Negroes from exercising many of the rights granted them. By 1876 whites had largely "redeemed" their state governments from Negro participation except in Florida, South Carolina and Louisiana. A compromise agreed to by Pres. Rutherford B. Hayes in 1877 between northern and southern industrialists and other northerners and southerners who had grown weary of federal intervention in the south completed the redemption and inaugurated a hands-off policy by the national government.

A bill passed by the house of representatives in 1890 on the recommendation of Pres. Benjamin Harrison, but defeated in the senate, 1891, for the federal supervision of federal elections led Mississippi to adopt in 1890 the first state constitutional amendment for the disfranchisement of most Negroes. Several decisions of the United States supreme court, especially from 1873 to 1910, also gave the south virtually a free hand in fixing the status of the Negro. These decisions nullified the reconstruction laws and the clauses in the 14th and 15th amendments for the protection of the civil and political rights of Negroes. In the famous case of *Plessy v. Ferguson*, 1896, the court for the first time sanctioned a state segregation law on the ground that it was a reasonable use of the police powers of the state, provided that the separate accommodations were "equal." The court also refused to intervene against state constitutional amendments that disfranchised most Negroes. But the court did hold that state action excluding Negroes from juries was unconstitutional.

This hands-off policy of presidents, congress and the supreme court encouraged the southern states to pursue their own policies. Early in the 20th century the southern states extended legislation, conforming to growing custom, that segregated Negroes in public places. One of the most extreme of the laws prohibited the storage together of textbooks used in white and Negro schools. By 1910 all the southern states had adopted constitutional amendments or laws that disfranchised most Negroes while permitting many equally unqualified whites to vote. Booker T. Washington, the



EBONY MAGAZINE

(LEFT) BOOKER T. WASHINGTON; (RIGHT) W. E. B. DU BOIS

Negro principal of Tuskegee institute, Alabama, had deemed it necessary in 1896 to seek a compromise based upon friendship with southern whites in place of federal action to provide job opportunities, schools and a limited participation in the suffrage. While the various amendments and laws were aimed at disfranchising some whites as well as Negroes, they affected the latter more than the former. In Louisiana, for example, the number of white registrants was reduced by only about 24% from 1897 to 1900 while the number of Negroes was reduced by more than 90%. An even larger percentage of Negroes was disfranchised by an Alabama amendment. While these were extreme cases and while there had been a general trend toward nonparticipation in elections, the amendments and laws, despite Washington's plea, disfranchised the vast majority of Negroes throughout the south.

Even before the adoption of these amendments and laws, force and intimidation had so reduced the number of Negro voters that the number of Negroes in congress and in the state legislatures had steadily declined. There had been seven in the house of representatives and one in the senate, 1875–77. The largest number thereafter had been three representatives and one senator, 1877–79. After 1891–93 there had been only one representative, and in 1901 George H. White of North Carolina was the last until Oscar DePriest was elected from Illinois in 1928. Whereas in 1877–78 there had been 39 Negroes in the South Carolina senate and house, at the end of the century there was only one. In the 20th century there were no Negro members of a southern state legislature until 1962 when LeRoy R. Johnson was elected to the Georgia senate.

Since there were fewer Negroes in the north, race relations created less friction there. Negroes voted more freely but they were so few in number that they did not have the power, as did some racial and religious blocs, to elect members of their race to congress, to state legislatures or to municipal councils. Negroes in the north suffered less segregation, discrimination and nonrecognition of their dignity as human beings. Following the supreme court decision of 1883 that declared unconstitutional the Civil Rights law of 1875, 15 northern states adopted new civil rights laws against discrimination by individuals in public places and three strengthened the provisions of existing laws.

2. The 20th Century.—World War I altered the status of the Negro in both the north and the south, and the process of change was accelerated during the New Deal era, during World War II and during the cold war with the Soviet Union. The migration of approximately 2,000,000 Negroes from the south to the north reduced the proportion of Negroes in the south and thereby facilitated the acceptance by southerners of the changes created by the improved economic status of Negroes and by the decisions of the U.S. supreme court. The migration provoked a few race riots in northern cities. The growing number of Negro voters gave them the balance of power in some elections; together with greater recognition of the capacities of Negroes, it increased their number in elective and appointive offices. For example, a Negro was elected as president of Manhattan borough, New York city, another as judge of the New York supreme court, and a third as deputy mayor of Cincinnati, O. By the early 1960s there were no Negroes in the U.S. senate and only five Negro members of the house of representatives, but there were about 50 Negro members of state legislatures and many Negro members of municipal councils. Negroes were appointed as state attorneys, circuit court judges and ambassadors; others held such posts as assistant secretary of labour, governor of the Virgin Islands, commissioner of the District of Columbia and director of the U.S. Information agency. In 1966 Robert C. Weaver was appointed secretary of the newly created department of housing and urban development.

3. Civil Rights.—Even before World War I the U.S. supreme court had handed down decisions that strengthened the civil and political rights of Negroes. In 1915, in its first decision in opposition to disfranchisement, the court had outlawed the "grandfather clause." This clause had made voting more difficult for persons who had not themselves voted on Jan. 1, 1866, or had a grandfather who had voted on that date. Another disfranchising device was the exclusion of Negroes from Democratic primaries in southern states. In a series of decisions beginning in 1927 and culminating in *Smith* v. *Allwright* (1944), the supreme court declared such exclusion unconstitutional. As a result of these decisions, Negro voting increased in almost all of the southern states.

In line with the supreme court's decisions of 1954 and 1955 outlawing segregation in public schools, and the Interstate Commerce commission's (ICC) ruling (1955) forbidding the segregation of interstate travelers on trains, buses and in waiting rooms, a few congressmen proposed bills to protect the civil and political rights of Negroes. President Eisenhower, on Jan. 5, 1956, called for the establishment of a bipartisan commission to investigate allegations of the denial of civil rights to Negroes in some localities.

On Aug. 29, 1957, the senate approved a house bill which for the first time in 82 years sought to protect the civil rights of Negroes. It established in the executive branch a six-member bipartisan Commission on Civil Rights, with subpoena powers, to investigate alleged deprivation of voting rights because of colour, race, religion or national origin; to study legal developments constituting a denial of equal protection of the laws; and to appraise federal laws and policies regarding equal protection of the laws. The law made interference with the right to vote in federal elections actionable at the discretion of the U.S. attorney general under injunctive proceedings in the U.S. district courts. The law also permitted federal judges to issue injunctions or other orders to protect the right to vote; and it maintained the courts' powers through civil contempt proceedings, without a jury, to secure compliance with, as distinguished from punishment for, violation of such orders. The commissioners, one of whom was a Negro, were directed to make a final report to congress within two years.

In several southern states in the early 1960s many Negroes were voting without special impediments, but in others such was not the case. Five states, for example, required the poll tax as a prerequisite for voting until adoption of the 24th amendment to the U.S. constitution in 1964 outlawed the poll tax as a requirement for voting for federal offices. On Nov. 2, 1954, Mississippi had adopted a new "grandfather clause" with Jan. 1, 1954, as the privileged qualifying date. On that date only 22,000 Negroes out of 500,000 of voting age had been registered. Alabama in 1957 gerrymandered the town of Tuskegee so as to exclude almost all of the Negro voters from the township. On Feb. 17, 1961, a lower federal court, acting on an order of the U.S. supreme court in *Gomillion* v. *Lightfoot*, ruled that this gerrymander was discriminatory and hence violated the 15th amendment. Alabama then adopted devices similar to those in other southern states, such as denial of registration for "bad writing," "bad character" or reasons unspecified, and the changing of the place of registration without proper notice. In some areas of Alabama with large Negro populations no Negroes at all were permitted to vote.

In order to forestall all such subterfuges and otherwise strengthen provisions dealing with discrimination, congress passed a second civil rights law in 1960. It provided: (1) that if a registration official resigned or was replaced prior to the institution of a suit to permit Negroes to vote, the proceeding might be instituted against the state; (2) that voting records be preserved for a period of 22 months following any general or special elections and that the attorney general of the U.S. be given access to records before a suit was filed; (3) that, where discrimination against Negro voters had been a practice, a federal judge might himself determine or might appoint referees to determine the eligibility of Negroes to vote.

Increased registration by Negroes produced tensions. In Fayette and Haywood counties, Tenn., in 1960, Negroes who registered to vote were evicted from the farms on which they worked and were subjected to economic reprisals. Action by the U.S. department of justice stopped some of the evictions and eased the economic reprisals. In Terrell county, Ga., Negro college graduates were not permitted to register, because they failed to pass reading tests. A U.S. district court in 1960 found that 30 Negroes had been denied the right to register because of their race, ordered four to be registered, and issued an injunction against further discrimination. In 1962, when Negroes again attempted to register, county officials used violence against them. At about the same time, a federal judge ordered that Negroes in a Louisiana parish

be registered in accordance with the terms of the 1960 civil rights law.

In Nov. 1963, when he became president, Lyndon B. Johnson made a strong appeal to congress for enactment of the civil rights bill that had been proposed by President Kennedy. After the bill passed the house in Feb. 1964, southern senators, organized by platoons, conducted a filibuster against it for 75 days; then on June 10, 1964, for the first time in history, cloture was invoked to end a filibuster on a civil rights bill. As in the house, bipartisan agreement, strongly supported by President Johnson, prevented any significant weakening of the bill in the senate. President Johnson signed it into law on July 2. The new law provided for strengthening federal authority to guarantee the voting rights of Negroes, to forbid racial discrimination in places of public accommodation and to encourage further desegregation of schools.

Voter registration drives were launched in southern states during the summer of 1964 but little progress was made in the face of determined opposition by white election officials. In Mississippi three civil rights workers (one Negro and two white men) were murdered and their bodies buried in an earthen dam near the town of Philadelphia. In March 1965, while Negro demonstrations against denial of the vote were being held in Selma, Ala., peaceful demonstrators attempting to march to Montgomery, the state capital, were clubbed and beaten by law enforcement officers. Later the Rev. James J. Reeb, a northern clergyman who had come to Selma to join the demonstrators, was attacked on the street by white men and fatally beaten. As tension mounted throughout the nation President Johnson addressed a special joint session of congress and made a fervent appeal for prompt enactment of a new and stronger right-to-vote law. After lengthy debate the new bill was passed during the summer of 1965.

Disproportionate representation of rural counties in state legislatures reduced the power of the more liberal urban voters and made doubly difficult the enactment of state legislation in support of civil rights laws. The U.S. supreme court's decision *Baker* v. *Carr* (1962) in effect ordered legislative reapportionment in Tennessee to eliminate rural dominance. Following this decision, suits were filed in several other states and on June 15, 1964, the supreme court ruled that representation in both houses of state legislatures must be based on population. But the big question still remained: if reapportionment did occur, would it greatly affect the rights of Negroes? One of the first fruits of reapportionment was the election of a moderate, Carl Sanders, as governor of Georgia over Marvin Griffin, a die-hard segregationist. Another fruit was evidence that, in Georgia, reapportionment also influenced elections to congress as well as to state legislatures. Reapportionment of the U.S. house of representatives after every census as prescribed by the constitution had been consistently effected. Reapportionment to reduce the number of southern representatives in accordance with the second section of the 14th amendment, however, had never taken place. The failure to enact this latter type of reapportionment, the use of the filibuster in the senate, the seniority of southern congressmen on important committees, and the inadequacy of support by the administration prevented the enactment in 1962 of any new civil rights legislation. On the other hand, a constitutional amendment prohibiting the requirement of a poll tax (*q.v.*) for voting in federal elections was ratified in 1964.

The virtual disappearance after 1950 of lynching (which had taken a toll of almost 900 persons, most of them southern Negroes, in the first decade of the 20th century) made an antilynching law less urgent. Negroes received added protection from supreme court decisions: over a span of years the court ruled that a Negro did not receive a fair trial in a court dominated by mob violence, in a court where Negroes were excluded from the jury, and in a court where Negro defendants were not adequately represented by counsel. (*See* LYNCHING AND LYNCH LAW.)

Several southern states sought to require the state branches of the National Association for the Advancement of Colored People (N.A.A.C.P.) to disclose the names and addresses of their members but on June 30, 1958, in *N.A.A.C.P.* v. *Alabama*, the U.S. supreme court struck down a $100,000 contempt fine imposed by Alabama because of refusal to disclose this information. In 196[illegible] the supreme court held unconstitutional Virginia laws which tried to restrict the activities of the N.A.A.C.P. on the grounds that they engaged in illegal barratry and unlawful solicitation of cases.

4. Nonviolent Protest.—Nonviolent protest against segregation by white and Negro individuals and groups in the United States has a long history. In the early 1940s protests that had largely been individual and sporadic became systematized and continual. About 1943 the Fellowship of Reconciliation organized small numbers of Negroes and whites to sit together in restaurants and other places of public accommodations to obtain service in Chicago, Cleveland and Washington. Members of this fellowship also flouted segregation on interstate buses and trains; at Chapel Hill, N.C., in 1947, participants in a "Journey of Reconciliation" were almost lynched. The Quakers and other church groups encouraged young people's activities against segregation. In 1953 the U.S. supreme court declared that the "lost laws" of the District of Columbia of 1872 and 1873 were valid. These stated that "a respectable, well-behaved person" had to be served without regard to race, colour or previous condition of servitude by keepers of hotels, restaurants and certain other public places.

Student "sit-ins" were organized in 1958 by N.A.A.C.P. youth councils in Wichita, Kan., and Oklahoma City, Okla. A sit-in of four Negro students from North Carolina Agricultural and Technical college at a Greensboro, N.C., lunch counter on Feb. 1, 1960 set off a succession of similar demonstrations. Within six months large numbers of Negroes, mostly students, accompanied by whites, peacefully protested against segregation. During the early 1960s several thousand students were arrested, a large number were jailed and hundreds were expelled from school.

Before the appearance of the sit-in movement, impatience at the slow rate of desegregation had spurred an assault upon the practice of requiring the use of separate facilities in interstate and intrastate travel. In 1955–56 the Rev. Martin Luther King, Jr. led a dramatic boycott against segregation on buses in Montgomery, Ala. When the bus company attempted to enforce state statutes and local ordinances requiring segregation, the U.S. district court in 1956 declared such statutes and ordinances unconstitutional. This decision, which was affirmed in the same year by the U.S. supreme court, formulated a ruling that was extended to the use of other public facilities such as swimming pools.

At the end of 1955 the Interstate Commerce commission ruled that the segregation of interstate travelers on trains or buses, and in waiting rooms, was forbidden as of Jan. 10, 1956. The "Freedom Rides," which began in May 1961, tested the compliance with this ruling by bus and railroad companies and law-enforcement officers in the south. Outside of Anniston, Ala., mobs attacked and burned a Freedom Riders' bus; in Birmingham, Ala., the police either stayed away from the place where the mob had gathered or did not protect the riders from vicious beatings; in Jackson, Miss., the police arrested the Freedom Riders on charges of disturbing the peace as soon as they arrived at the bus station. Violence, wholesale arrests and imprisonment led Atty. Gen. Robert F. Kennedy to request the ICC to issue a strongly worded set of regulations amplifying the ban on segregation in interstate travel. The ruling was issued in Sept. 1961. The attorney general also sent U.S. marshals and agents of the Federal Bureau of Investigation to guarantee protection to the Freedom Riders where inadequate protection was provided by local authorities; in Montgomery, Ala., the U.S. marshals used tear gas to protect a Negro church meeting from a mob. On May 24, 1961, the attorney general publicly requested a "cooling off period" in which the demonstrations and the violent responses to them should be discontinued. Although the events in Alabama and Mississippi became less sensational, the Negro's impatience with segregation did not appreciably cool, but was manifested in other areas.

The "Albany movement" grew out of rising indignation at the long-established and almost total segregation in this quiet city in southern Georgia. In early 1961 the city commissioners ignored a request by Negro leaders to desegregate certain city facilities and the mayor refused to appoint a biracial committee. The Atlanta-based Student Nonviolent Coordinating committee and the

Youth Council of the local N.A.A.C.P., restive at the slowness of change in the patterns of segregation and discrimination, served as a catalyst for the Albany movement, which was formally organized on Nov. 17, 1961. Headed by W. G. Anderson, the movement attacked discrimination on buses, in bus and train stations, libraries, parks, hospitals, public and private employment, and on juries, and denounced police brutality. A series of nonviolent, direct-action protests to test the validity of the ICC prohibition of segregation resulted in arrests, imprisonment and fines and was climaxed by the arrest at the railway terminal of nine Freedom Riders (Negro and white) on Dec. 10, 1961. Two days later about 300 demonstrators were arrested on charges of parading without a permit, unlawful congregating on the sidewalk and unlawful assembly. As the demonstrations continued and the jails filled up, Gov. Ernest Vandiver called 150 national guardsmen to duty in Albany and assured Attorney General Kennedy that he and the mayor could handle the situation. Negotiations between the leaders of the movement and city officials resulted in an oral agreement on Dec. 18 that: (1) the city would desegregate train and bus facilities; (2) all of the imprisoned, with the exception of the nine Freedom Riders, would be released from jail on the signing of simple property bonds; (3) the bonds of the Freedom Riders would be reduced; (4) further demonstrations would be called off; and (5) the city would hear the Negro community's case at the first business meeting of the new city commission. In little more than a month, however, Negroes contended that the officials had not lived up to their agreement and instituted a boycott of the city buses and a "selective buying" campaign. National attention was stirred by further demonstrations and arrests. The department of justice sent FBI agents to the scene and directed its lawyers to file a brief in U.S. district court opposing a request by Albany officials to bar demonstrations. The ministers of the nation were especially concerned, organizing a picket line at the White House and pilgrimages to Albany. One interracial group from the New York and Chicago areas, comprising Jewish, Protestant and Catholic clergymen and laymen, visited Albany in protest against the jailings. All 75 were arrested and jailed. The burning of churches and the intimidation of Negro registrants in neighbouring counties provoked Pres. John F. Kennedy on Sept. 13, 1962, to denounce the "outrageous" actions, and caused investigations by the justice department.

During April 1963 civil rights demonstrations began in Birmingham, Ala., led by the Rev. Martin Luther King, Jr., among others. Hundreds of demonstrators were arrested by policemen whose use of fire hoses and police dogs aroused public revulsion. The situation became so serious in May that President Kennedy stationed 3,000 federal troops near Birmingham to be on hand if needed to maintain law and order. During the following months there were protest demonstrations in many other towns and cities, often accompanied by violence. In June the Mississippi state field secretary for the N.A.A.C.P., Medgar Evers, was shot and killed as he entered his home in Jackson, Miss. A white Mississippian was later arrested and charged with the killing.

The high point of the year's demonstrations came in August when more than 200,000 Negro and white citizens staged a "march on Washington," the largest demonstration of its kind ever held in the nation's capital. The marchers gathered at the steps of the Lincoln memorial to hear speakers voice the Negroes' demand for equal rights. Leaders of the movement conferred with President Kennedy and with members of congress.

In 1964 several civil rights groups attempted to break down the barriers to Negro voting in the deep south. They organized volunteers to go to Mississippi to take part in a statewide effort during the summer to educate Negroes in "freedom schools" and have them registered as voters. They met with resistance at every turn and, as noted above, three of them were murdered. More than a score of Negro churches in Mississippi were totally or partially destroyed by fire during the summer. Unable to register Negroes to take part in Democratic party primary elections, the civil rights workers registered thousands of Negroes on the rolls of the Mississippi Freedom Democratic party and sent delegates to the Democratic national convention where they unsuccessfully challenged the seating of the all-white Mississippi delegates.

The campaign to gain voting rights for Negroes was renewed in 1965 and soon reached a climax in March at Selma, Ala., where police officers were charged with using undue force to stop a proposed protest march to the state capital. A federal district judge upheld the right of the Negroes and their white sympathizers to carry out the march. When the governor of the state pleaded inability to provide protection all along the 50-mile route from Selma to Montgomery, President Johnson called the Alabama national guard into federal service to cooperate with U.S. marshals, FBI agents, some U.S. army troops and local police officials to protect the marchers. Led by two Nobel prize winners—the Rev. Martin Luther King, Jr., and Ralph J. Bunche—and supported by thousands of white and coloured citizens from all over the nation, the march reached the Alabama capital on March 25. That evening, as the marchers were dispersing to their homes, Mrs. Viola Liuzzo of Detroit, Mich., was shot and killed in her car after having taken demonstrators back to Selma. Within a matter of hours President Johnson announced on radio and television that FBI agents had taken into custody four members of the Ku Klux Klan who were thought to be responsible for the slaying. He further stated that legislation to bring the activities of the Klan under "effective control of the law" would soon be submitted to congress and he called upon all members of the Klan to withdraw from it "and return to a decent society before it is too late."

5. Extremist Movements.—Black chauvinism had reached its height in the United States during the 1920s when Marcus Garvey, a Jamaica-born Negro, won a large number of adherents to his "back-to-Africa" and separatist movements. After his deportation in 1927, Garveyism declined. During the 1930s the Communist party of the United States advocated the creation of a separate nation in the southern black belt; most Negroes repudiated this type of solution.

At the beginning of World War II a few Negroes proclaimed themselves "Muslims" in a vain attempt to evade the draft. The leader of this group, who called himself Elijah Muhammad, exploited the legitimate grievances of Negroes, and with oratorical and organizational skill developed a cult which in the early 1960s numbered about 70,000. Although the Islamic Church repudiated them as not being true followers of its faith, the "Black Muslims" practised discipline and asceticism, and professed certain Islamic beliefs. Their leaders preached black supremacy and complete separation of the races, including a black nation within the United States. This preachment provided ammunition for segregationists and white supremacists but alienated most Negroes and their supporters. The greater appeal of the cult lay in fervid exposure of the white man's inhumanities. *See* also BLACK MUSLIMS.

IV. EDUCATIONAL DEVELOPMENTS

1. Post-Emancipation Years.—When the 13th amendment emancipated all slaves in the United States in 1865, the vast majority of Negroes were illiterate. Some free Negroes had learned to read and write, and even some privileged slaves had illegally secured the rudiments of an education. The education of the freedmen was, therefore, one of the urgent tasks before the nation at the end of the Civil War. As early as 1862 religious and philanthropic organizations began the task of establishing schools for Negroes. Freedmen's relief associations in northern cities and Quakers, Congregationalists and other church groups founded schools in the wake of the Union armies in the south. In the last year of the war at least a thousand northern men and women were teaching and caring for former slaves. In 1865 the major responsibility for educating the emancipated Negroes was assumed by the Freedmen's bureau although denominational and philanthropic agencies continued to maintain schools. By 1870, when the educational work of the bureau stopped, there were 247,333 Negro pupils in 4,329 schools; and more than a dozen of the major institutions for the higher education of Negroes had been founded, including Fisk university, Howard university and Atlanta university, all of which provided a liberal arts curriculum, and Hampton institute, which emphasized vocational training.

Meanwhile, as the Republican party established "radical" gov-

ernments in the southern states and disfranchised those who had supported the Confederacy, new constitutions were written in all the former Confederate states. One of the most important features of these new frames of government, to which Negro delegates to conventions contributed, was the provision for free public education. In a few states, such as South Carolina and Louisiana, there were some experiments with mixed schools, but whites were generally opposed to them. When Reconstruction ended in 1877 and "home rule" was restored, the southern whites in control of their state governments continued to support programs of public education, but they soon developed practices of discriminating against Negro schools in buildings, equipment, teachers' salaries and the like. By 1877, for example, Alabama was spending 50% more on the education of each white child than on the education of each Negro child, and the figure rose to 514% by 1909. It became necessary, therefore, for Negroes themselves to supplement public support of their schools through private assistance of various kinds. They were aided by numerous philanthropic agencies such as the Slater fund, the Peabody fund and the Jeanes fund (*see* FOUNDATIONS, PHILANTHROPIC). During this period new schools and colleges for Negroes were established, including Tuskegee institute and several land-grant colleges.

By 1900 there were 1,500,000 Negro children enrolled in school, and there were 28,560 Negro teachers. At the same time more than 2,000 Negroes had graduated from college, while 700 were enrolled in institutions of higher learning. Despite large contributions from philanthropists and other donors, both Negro and white, schools and colleges for Negroes were unable to attain equality with those provided for whites.

2. The 20th Century.—In 1900, for every $2 spent by the southern states for the education of Negroes, $3 was spent for whites. This disparity worsened with time; in 1930 for every $2 spent by the southern states for the education of Negroes, $7 was spent for whites. Outraged at the travesty of the doctrine of separate but equal as seen in inequitable allocation of state funds, inferior schools, shorter terms, lower salaries, and the lack of provision for graduate and professional education, Negroes instituted anti-discrimination suits.

In 1935 the Maryland court of appeals ruled that a Negro should be admitted to the state university's law school and that out-of-state tuition grants made to obviate such admission were a denial of equal protection of the laws. In 1938 the U.S. supreme court confirmed this ruling in a case involving the University of Missouri law school and held that substantially equal facilities must be provided within the state. Two years later the U.S. circuit court of appeals ruled that a double salary standard in Norfolk, Va., based on race was unconstitutional. Southern states feverishly set up graduate and professional schools for Negroes and strengthened the public schools and colleges for Negroes in the hope that the court would approve their efforts to fend off, by "equalizing" within the state, the loss of separateness. Their efforts were futile. In 1950 the supreme court ruled that Negroes had the right to attend the same professional schools that whites attended, under the same conditions. On May 17, 1954, the supreme court unanimously ruled (*Brown* v. *Board of Education*) that, even though Negro and white public schools had been or were being equalized with respect to buildings, qualifications, salaries of teachers and other "tangible" factors, segregation in public schools solely on the basis of race was unconstitutional. The court thus reversed the "separate but equal" doctrine of *Plessy* v. *Ferguson*. Racial segregation in states violated the equal protection clause of the 14th amendment; in the District of Columbia it violated the due process clause of the 5th amendment. On May 31, 1955, the court ordered the states which had separate public schools to desegregate "with all deliberate speed." This decision was resisted by most governors and legislators of southern states, by southern members of the U.S. congress, and by newly formed White Citizens Councils and vigilante groups.

Every southern state attempted to circumvent the decision, some by devious legislation and policies, and others by outright defiance. In Little Rock, Ark., in Sept. 1957, Gov. Orval Faubus ordered the national guard to prevent Negro children from attending Central high school. In December President Eisenhower sent federal troops to the scene; they dispersed mobs and guarded the Negro children on their way to and from school, and within the school. Governor Faubus ordered Central high school closed during the school year 1958–59. On Sept. 29, 1958, the supreme court ruled that the desegregation of public schools could not be nullified openly and directly by state legislators or state executive or judicial officers, nor indirectly by them through evasive schemes. It was not until 1959 that school desegregation was uninterrupted in Little Rock. Prince Edward county, Va., which closed its public schools rather than desegregate, was a striking illustration of resistance tactics. After years of litigation the U.S. supreme court on May 25, 1964, ruled that one county in a state cannot abandon public education to avoid desegregation while public schools are supported elsewhere in the same state.

Disregarding the lesson of Little Rock, Gov. Ross Barnett of Mississippi defied federal court orders to admit a Negro, James H. Meredith, to the state university at Oxford. The registration was thrice denied by the governor or by the lieutenant governor acting as college registrar. On Sunday, Sept. 30, 1962, Meredith was escorted to a dormitory on the campus of the university by U.S. marshals, FBI agents and department of justice lawyers. That evening President Kennedy, in a nationwide telecast, stated the primacy of federal law and the government's determination that Meredith would be enrolled in the university, and appealed for calmness and restraint. While he was speaking, an unruly mob of both students and outsiders attacked the federal marshals, who were forced to use tear gas to protect themselves. After the state police withdrew, the federalized national guard and regular army troops were called in to disperse the mob. They restored order in Oxford and the surrounding countryside and provided close protection to Meredith during his first weeks on the campus. Governor Barnett's refusal to comply with the orders of the circuit court of appeals not to obstruct Meredith's attendance at the university caused him to be charged with contempt of court.

By the summer of 1964—ten years after the supreme court's decision—Mississippi was the only state that had not desegregated its public schools below the college level, though desegregation had barely started in South Carolina and Alabama. Elsewhere the decree of the supreme court met with greater compliance, but desegregation was only on a token basis. Of the 2,265 school districts in the states of the old Confederacy that had been segregated before 1954, only about 250 had started desegregation and many of these had only a scattering of Negro pupils. Of the 2,800,000 Negro children in the south, fewer than 10,000 were estimated to be in classes with white children. The rate of desegregation was higher in the border states and in the District of Columbia.

In northern cities, segregated schools, though without legal sanction, increased because of the concentration of Negroes in restricted residential areas. Such methods as establishing attendance zones, controlling transfers and assignments, selecting new sites for schools, and gerrymandering of school districts created or helped to preserve segregation in public schools in the north. In some cities strong forces opposing this *de facto* segregation succeeded in having Negro children and, in fewer numbers, white children transferred to schools outside their residential school districts.

By the early 1960s more than 300,000 Negroes had graduated from college; the majority were graduates of Negro colleges, but a sizable number were graduates of predominantly white colleges of the unsegregated states. Over 1,000 Negroes attended "white" tax-supported institutions in the south and another 1,000 attended southern private institutions of higher learning. The instructional staffs of most Negro colleges were interracial, and Negro professors in increasing numbers were appointed to the faculties of leading northern, midwestern and western universities; a few served as heads of their departments.

V. MILITARY HISTORY

Negroes fought in all the wars waged by the colonies and the United States. Crispus Attucks, a runaway slave, was the first to fall in the Boston massacre, 1770. About 5,000 Negro soldiers, free and slave, served in the Revolutionary army and others in

the navy, especially as coastal pilots. A few served as sailors during the hostilities with France, 1798–1800. Negro soldiers and sailors participated in the War of 1812, notably with Capt. Oliver H. Perry on Lake Erie and with Gen. Andrew Jackson at New Orleans. A very small number saw service in the Mexican War. Pres. Abraham Lincoln doubted whether the Union would have won the Civil War had it not been for the effective conduct of more than 178,000 Negro troops. After the war the federal government organized six regiments which were consolidated into the 9th and 10th cavalry, the 24th and 25th infantry. These troops helped conquer the Indians during the 1870s and the 1880s. With six volunteer state regiments and four raised by the war department, they gained distinction during the Spanish-American War.

About 342,000 Negro soldiers served during World War I, approximately 100,000 overseas. Two infantry divisions, the 92nd and 93rd, fought in several important battles, especially in the Champagne and the Argonne sectors. Most, however, were in labour battalions that unloaded ships and sent supplies to the front. After World War I most of the combat troops were reduced to service units, and the navy assigned most Negroes to be mess attendants. On the other hand, largely as a result of pressure by Negro veterans and the Negro press, the United States Military academy at West Point, N.Y., and the United States Naval academy at Annapolis, Md., admitted and graduated qualified Negroes. In 1940 President Roosevelt promoted Col. Benjamin O. Davis to the rank of brigadier general of the army, the first Negro to attain general officer rank.

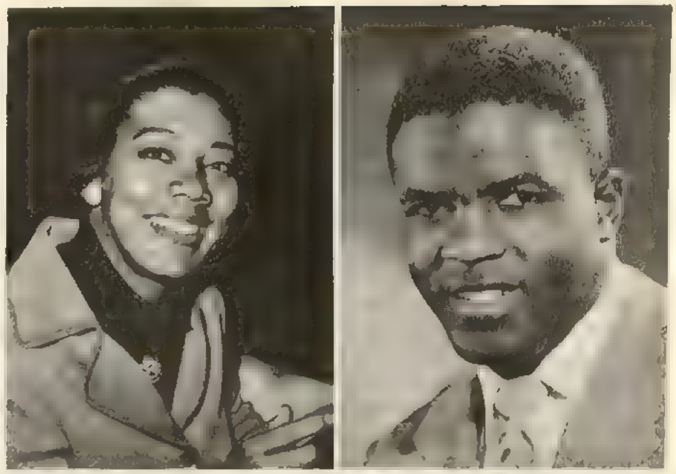
During World War II, 1,174,000 Negroes were inducted and enlisted in the army, navy, the marine corps (for the first time in 167 years) and the coast guard. Approximately 700,000 fought in most of the theatres of war from Pearl Harbor to the surrender of Germany and Japan. Negro and white officers, except in the air force, were trained together. The number of Negro officers rose to a peak of 7,768. Toward the end of the war a beginning was made toward integration of Negro and white troops. Integration was continued in all branches of the service after the war, was increased during the Korean War and accelerated after it. The integration included almost all the public schools on military installations, even in the south. Despite significant gains, however, Negro army officers were only about 2% of the total in the early 1960s. The proportion of enlisted men was considerably higher. In 1959 President Eisenhower promoted Brig. Gen. Benjamin O. Davis, Jr., son of the first Negro general in the army, to the temporary rank of major general of the air force. General Davis served in 1959 as deputy chief of staff of the U.S. air force in Europe and in 1962 was director of manpower and organization in the office of the deputy chief of staff of the air force. Each year a few Negroes were admitted to the U.S. Military academy, Naval academy, Air Force academy and Coast Guard academy.

VI. SPORTS

In sports, where the United States achieved one of its best publicized manifestations of democracy, Negroes won much recognition. In boxing, Negro fighters were remarkably successful. In 1908, Jack Johnson became the first Negro to win the world heavyweight title. Joe Louis (*q.v.*) won this title in 1937 and held it until he retired undefeated in 1949, a longer tenure than that of any other heavyweight champion. Other Negro boxers—Ezzard Charles, "Jersey Joe" Walcott, Floyd Patterson, Charles "Sonny" Liston and Cassius Clay—held the heavyweight title at various times after Louis' retirement. Among the Negro champions in other boxing classes were Henry Armstrong, "Sugar" Ray Robinson and Archie Moore. (*See* also BOXING.)

WIDE WORLD

JOE LOUIS



(LEFT) WIDE WORLD; (RIGHT) MILTON MELTZER

(LEFT) ALTHEA GIBSON; (RIGHT) JACKIE ROBINSON

In track and field events the record of the Negro was not as extensive as in boxing but it was equally impressive. The outstanding star was Jesse Owens, who won four events—breaking three records and tying a fourth—before the startled eyes of Adolf Hitler in the Berlin Olympics of 1936. Other Negroes, both men and women, have been stars in track and field events in national and international meets, and since before World War II have been mainstays of the U.S. Olympic teams. Wilma Rudolph dominated the women's sprints in the Olympics of 1960. Another Negro woman athlete to achieve eminence was Althea Gibson; in 1957 and 1958 she won the British women's single tennis championship at Wimbledon and the United States women's singles championship at Forest Hills.

Baseball, the national sport, broke a long tradition in 1947 when Jack Roosevelt ("Jackie") Robinson was signed up by the Brooklyn Dodgers as the first recognized Negro to play on a major league team. Negro players were soon generally accepted in both major and minor leagues and were prominent in the all-star games. Among the best known were Roy Campanella, Don Newcombe, Larry Doby, Willie Mays, Hank Aaron, Ernie Banks, Maury Wills, Elston Howard, Vic Power and Orlando Cepeda.

Football was long the favourite sport in Negro colleges but the Negro players who became nationally known were those on the teams of leading northern, midwestern and western colleges and universities. Among the many Negro professional football players the following became outstanding stars: Marion Motley, Jim Brown, Buddy Young, Len Ford, Lenny Moore, Bobby Mitchell, Ollie Matson, John Henry Johnson, Eugene ("Big Daddy") Lipscomb, Roosevelt Grier and Roosevelt Brown. In basketball, both amateur and professional, Negroes were also prominent. One all-star collegiate team included four Negroes; in professional basketball Bill Russell, Elgin Baylor, Oscar Robertson and Wilt "the Stilt" Chamberlain were among the most-feared competitors, and the Harlem Globetrotters gave amazing exhibitions in the United States and around the world. The ability of the Negro in sports, especially as communicated to the nation by way of radio and television, was a force that increased respect for the Negro race.

VII. CULTURAL AND INTELLECTUAL DEVELOPMENTS

1. Religious and Social Organizations.—From the end of the 18th century the Negro church has been an important agency in the social and cultural development of Negroes. During the post-Reconstruction years, Negro Baptists and Methodists were most numerous, but newer Protestant denominations and the Roman Catholic church attracted increasing numbers. In the 20th century the Roman Catholic church's intensified proselytizing of Negroes enlarged the proportion of Negro Catholics to Negro Protestants. Organized cults and random "store-front" churches appealed to many Negroes who did not feel at home in the more conventional denominations and were attracted by flamboyant,

prophetic personalities. Although Christian churches for a long time had perpetuated segregation, some church leaders after World War II recognized and supported steps toward integration. The Roman Catholic church went further than the Protestant churches in desegregating churches, but the Unitarian, the Christian Congregationalist and the Presbyterian churches were also active in opposing segregation. Occasionally interracial congregations and pastorates were found; one notable instance was the Church for Fellowship of All Peoples, in San Francisco. Negro churches had long rendered social services by maintaining nurseries, employment bureaus and evening schools; in the 20th century their activities extended to economic and political programs. Fraternal orders, such as the Masons, Knights of Pythias, the Elks and secret benevolent societies, emerged to meet the social needs of Negroes.

2. Literature.—The intellectual growth of the Negro and his progress toward greater assimilation in American life were notably reflected in the literary activity of the post-Reconstruction years. Frederick Douglass, who had first published a sketch of his life in 1845, issued the final version of his autobiography, *The Life and Times of Frederick Douglass*, in 1892. In 1901 Booker T. Washington brought out his *Up From Slavery*, which rapidly became one of the classics of American biography. The first outstanding Negro historian was George Washington Williams, whose groundbreaking volumes, *History of the Negro Race in America* and *History of the Negro Troops in the Rebellion*, were published in 1883 and 1887 respectively.

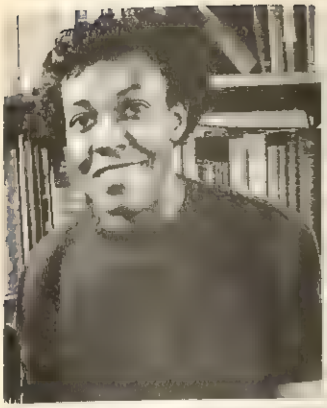
At the end of the century the most popular Negro writer yet to appear was Paul Laurence Dunbar, often called the poet laureate of his people. Such volumes as *Oak and Ivy* and *Lyrics of Lowly Life* interpreted the Negro folk in their own dialect with humour and pathos. Dunbar also wrote poems in standard English on traditional themes; in many of these poems he protested against injustice. Dunbar also attempted prose fiction but was less successful than Charles W. Chesnutt, who dealt engagingly with folk beliefs in *The Conjure Woman* and trenchantly with problems of the new freedmen in *The Marrow of Tradition* and *The Colonel's Dream*. Chesnutt's social concern was shared and deepened by W. E. B. Du Bois (*q.v.*), whose "The Suppression of the African Slave-Trade to America" (1896) was the first monograph in the *Harvard Historical Studies*. In 1903 he published *Souls of Black Folk*, a book unmatched in its impact upon Negro intellectuals. Publications such as *The Philadelphia Negro* (1899) and the *Atlanta University Studies* (1897–1911) were models of sociological investigation. As editor of the *Crisis*, the organ of the N.A.A.C.P., for over a score of years he castigated the conscience of America and strengthened the protest of younger generations. His *Black Reconstruction in America*, by stressing economic factors and the constructive, though thitherto underestimated, participation of Negroes in American history, gave new impetus to historiography. *Black Folk Then and Now*, tracing the history of the Negro in the old world and the new, revealed not only Du Bois' scholarship but also his polemical power in its exposure of colonialism and racism. His other works—poetry, autobiography, biography and fiction—revealed his versatility. But the wide range, the diverse styles and the combination of passion, irony and learning in his works did not conceal the unity of his purpose: a new and truer emancipation from discrimination and misunderstanding. A pioneer at the end of the 19th century, he continued as an influence on the cultural life of America throughout the first half of the 20th century.

Negro editors of newspapers and magazines were preoccupied with fighting for justice and fuller opportunities for Negroes in American life. Magazines like the *Southern Workman*, published at Hampton, Va., after 1872, and the *A.M.E. Church Review*, begun in 1884 in Philadelphia, Pa., were concerned primarily with educational, literary and religious matters. In Boston in 1901 George Forbes and W. Monroe Trotter began publication of the *Boston Guardian* which, in contrast to the prevailing conciliatory program of Booker T. Washington, demanded immediate equality for the Negro. Such crusading, combined with growing race consciousness and a coverage of racially relevant activities that were neglected in white newspapers, brought about a flourishing, vigorous Negro press. The *Age-Defender* and *Amsterdam News* (New York city), the *Afro-American* (Baltimore, Md.), the *Journal and Guide* (Norfolk, Va.), the *Pittsburgh Courier* (Pa.) and the *Chicago Defender* (Ill.) enjoyed large national circulations, while hundreds of small weekly papers served other communities. In the 20th century there have been many Negro magazines; two of the most influential of these have been *Opportunity*, published for many years by the National Urban League and *Crisis*, the official organ of the N.A.A.C.P. The John H. Johnson publications, *The Negro Digest*, *Ebony* and *Jet*, were the most popular among Negro magazines. Scholarly journals published by Negroes included the *Journal of Negro History*, created in 1916 and first edited by Carter G. Woodson for the Association for the Study of Negro Life and History; the *Journal of Negro Education*, published since 1932 at Howard university, and *Phylon*, published since 1940 at Atlanta university. The influence of these Negro publications, both the widely popular newspapers and the learned journals, has been significant.

In the years following World War I the number of recognized Negro poets, essayists and novelists was so large that together they constituted what was known as the "Harlem Renaissance." Many of them published their first works in *Crisis* and *Opportunity*, which were edited by W. E. B. Du Bois and Charles S. Johnson respectively. In 1925 Alain Locke edited *The New Negro*, a representation and interpretation of the new literary and social movements. As influential as these three editors was James Weldon Johnson, who served as model and mentor to the newer generation of writers. Johnson's *Fifty Years and Other Poems* (1917) combined Dunbar's genre portraiture and more militant interpretations and credos; his *Autobiography of an Ex-Coloured Man* (1927), presented with a quiet but effective irony, was a pioneering novel that anticipated the themes of much later fiction. Of special value was Johnson's informed and sympathetic presentation of ragtime, of Negro folk music and religion, and in general of the Negro's creative genius. Johnson's position—that the Negro had made real contributions to American culture—was supported by his editing of *The Book of American Negro Poetry* (1922, revised and enlarged 1931) and two books of Negro spirituals. Johnson's own creative career was climaxed by *God's Trombones* (1927). His *Black Manhattan*, an informal history of the Negro in New York, and *Along This Way*, an autobiography, were important revelations of the Negro's role in America. A portion of the latter work, dealing with the revolution in Nicaragua (1909), together with his protests against the U.S. occupation of Haiti, and such domestic injustices as disfranchisement and lynching showed that Johnson, like his colleague Du Bois, was a master of both creative and polemical styles.

Poets of the "Harlem Renaissance" included Claude McKay, alternately bitter at America's injustice and nostalgic for his native Jamaica, who urged racial solidarity; Georgia Douglas Johnson, who published lyrical poetry in *The Heart of a Woman* and *Bronze;* Countee Cullen, who expressed the emotions and ideas of the "New Negro" in technically finished traditional verse in *Color*, *Copper Sun* and *The Black Christ*. Writing in a freer form, Langston Hughes with his *Weary Blues* (1926) started a poetic career of interpreting Negro life, especially the urban masses, that extended through *Montage of a Dream Deferred* (1951) and *Ask Your Mamma* (1961). The poetry of the "Harlem Renaissance" was race conscious; its best achievement was the communication of sincere and thitherto unexpressed feelings and attitudes. Later Negro poets were influenced by the regionalism and social awareness of the 1930s and afterwards. They included Sterling Brown's *Southern Road* (1932), Margaret Walker's *For My People* (1942), Owen Dodson's *Powerful Long Ladder* (1946), and M. Beaunorus Tolson's *Rendezvous With America* (1944) and *Libretto for the Republic of Liberia* (1953), and Gwendolyn Brooks's *Street in Bronzeville* (1945) and *Annie Allen* (1949), for which she was awarded the Pulitzer prize for poetry.

The union of literary and propagandistic interests seen in Du Bois and James Weldon Johnson was continued by Walter White in his protest novel, *Fire in the Flint* (1924), and his *Rope and Faggot: a Biography of Judge Lynch* (1929). Jessie Fauset, in such novels as *The Chinaberry Tree* (1931), and Nella Larsen



MILTON MELTZER

(LEFT) GWENDOLYN BROOKS; (RIGHT) RICHARD WRIGHT

with her *Quicksand* (1928) wrote of the Negro middle class and its problems. Harlem life was delineated in such fiction as Claude McKay's *Home to Harlem* (1926), Rudolph Fisher's *Walls of Jericho* (1928), George Schuyler's *Black No More* (1931) and Wallace Thurman's *Infants of the Spring* (1932). Jean Toomer's *Cane* (1923) was a poetic rendition and interpretation of Negro life in both rural Georgia and border cities.

Much of the literature about Harlem was marked by hedonism and lightheartedness; the fiction written by Negroes in the 1930s and after was more sober and grounded in social reality and history. Arna Bontemps' *Black Thunder* (1936) dealt with a slave revolt in 1800; Richard Wright in all of his fiction from *Uncle Tom's Children* (1931) through *Native Son* (1940) to *The Outsider* (1953) dealt with the Negroes' revolt and alienation. Zora Neale Huston recorded Negro folk material in *Mules and Men* (1935) and used folk backgrounds for her best fiction. The plight of the urban masses and frustrated Negro intellectuals was grimly handled by Chester Himes and Ann Petry. Willard Motley's naturalistic novels such as *Knock on Any Door* (1947) and *We Fished All Night* (1951), and Frank Yerby's long series of historical novels, beginning with *Foxes of Harrow* (1946), were instances of books by Negroes that do not deal mainly with Negro characters; both novelists were popular in their respective fields. Concern for the meaning of Negro life in America is central in the *Invisible Man* (1952) by Ralph Ellison, an avant-garde novelist. This concern and complexity of interpretation were found in the essays, *e.g., Nobody Knows My Name* and *The Fire Next Time* (1963), and the fiction, *e.g., Go Tell It on the Mountain* (1953) and *Another Country* (1962), by James Baldwin.

Two novelists who might be considered representatives of the angry young men school were Julian Mayfield, author of *The Hit* and *The Grand Parade*, and John O. Killens, author of *Youngblood* and *And Then We Heard the Thunder* (1963). Langston Hughes made use of a cutting folk irony and humour in his anecdotes of a Harlem character misnamed Simple.

3. The Dramatic Arts.—In the dramatic arts, as subject, playwright and actor, the American Negro played a significant role. *Uncle Tom's Cabin*, adapted from Harriet Beecher Stowe's novel, was one of America's most popular plays; black-face minstrelsy loosely based on Negro song and dance was long America's favourite theatrical fare. After World War I interest in Negro life was shown by Eugene O'Neill in *The Emperor Jones* (1920), by Paul Green in folk plays of Negro life in the south, and by DuBose Heyward and Dorothy Heyward in *Porgy*. The collaboration of George and Ira Gershwin with the Heywards transformed this play into the folk opera *Porgy and Bess*, which won national and international acclaim. Of the few plays by Negro authors that were seen on Broadway, the most notable were *Mulatto* by Langston Hughes, *Native Son*, a collaboration between Paul Green and Richard Wright, *A Raisin in the Sun* by Lorraine Hansberry and *Purlie Victorious* by Ossie Davis. All of these plays brought greater perception of Negro life to the stage.

Drama flourished in Negro colleges; the dramatic troupes of Howard university and of Florida Agricultural and Mechanical State university were governmentally sponsored for visits abroad, the former going to Denmark and Norway and the latter to west African countries. Outstanding Negro actors on the professional stage included Charles Gilpin, famous for the title role in *The Emperor Jones;* Paul Robeson, for his role in O'Neill's *All God's Chillun Got Wings* and the leading role in *Othello;* and Richard B. Harrison for his role as "De Lawd" in Marc Connelly's *The Green Pastures.* Actresses included Rose McClendon, Abbie Mitchell, and, after long years as a jazz singer and entertainer, Ethel Waters; actors included Frank Wilson, Canada Lee and Sidney Poitier. In 1964 Poitier became the first Negro to win the best-actor award of the Academy of Motion Picture Arts and Sciences. He won the award for his performance in *Lilies of the Field.*

The song-and-dance tradition among Negro performers extended as far back as the all-Negro shows at the end of the 19th century, when such stars as Bert Williams and George Walker entertained America. The mimicry of Bert Williams became so famous that Ziegfeld broke historic precedent by featuring him in his *Follies*, and phonograph records of his clowning were best sellers. Musical revues such as *Shuffle Along, Blackbirds* and *Carmen Jones* were highly successful. Many Negroes became well known on the stage, in motion pictures and on television; these included Bill Robinson, "Pegleg" Bates, Fredi Washington, Hattie McDaniel, Louise Beavers, Lena Horne, Dorothy Dandridge, Juano Hernandez and Frank Silvera. Hattie McDaniel won the 1939 Academy award as best supporting actress for her performance in *Gone With the Wind.* Diahann Carroll, who played a leading role in *No Strings*, a musical comedy by Samuel Taylor and Richard Rodgers, became a star on Broadway. The new respect and knowledge about authentic Negro folk music stimulated by the discoveries of Leadbelly (Huddie Ledbetter) and Josh White and the Library of Congress folk archives, led to the wide acceptance of such performers as Harry Belafonte and Odetta. (*See* FOLK SONG, U.S.) The influence of the Negro on American popular, ballroom and stage dancing had started with blackface minstrel shows; in the 20th century two able students and performers of the dance, Katherine Dunham and Pearl Primus, illustrated the relationship between the dances of Africa, the Caribbean countries, South America and the United States.

4. Music.—In the early decades of the 20th century a vogue was established on the concert stage by such singers as Harry Burleigh, Roland Hayes, Paul Robeson, Marian Anderson and Dorothy Maynor. Negro singers continued to achieve distinction. Mattiwilda Dobbs, Robert McFerrin and Leontyne Price performed with the Metropolitan Opera company. The choral singing of Negroes had been well received ever since the years shortly after the Civil War when the Fisk Jubilee singers successfully toured in the United States and abroad. The Howard university choirs, under the direction of Warner Lawson, frequently sang in joint concerts with the Washington National Symphony orchestra. The 60-voice Howard University choir, under

(LEFT) GEORGE WASHINGTON CARVER; (RIGHT) RALPH J. BUNCHE

the auspices of the president's special international program for cultural presentations, gave concerts in 15 countries of Central and South America and in three Caribbean countries. Other distinguished choral groups were the Hall Johnson choir, the Eva Jessye choir, and the De Paur Infantry chorus. Many fine voices, such as those of Todd Duncan, Anne Brown, Laurence Winters and Camilla Williams, were revealed to America at large in *Porgy and Bess* and the choral singing in that opera was highly praised.

Negro folk music and jazz (*q.v.*) were accorded careful study, documentation and critical appreciation in the United States, Europe and Asia. The spirituals had been accepted and praised since the Civil War, but it was not until the 20th century that Negro work-songs, reels, ballads and blues won esteem and understanding. Evolving from Negro folk songs (sacred and secular), Spanish, French and Anglo-Saxon popular music, and marching band music, jazz became America's most distinctive musical form. King Oliver, Louis Armstrong, Ferdinand "Jelly Roll" Morton and W. C. Handy played key roles in its origin; Fletcher Henderson, Duke Ellington, Jimmy Lunceford, Cab Calloway and Count Basie brought about its evolution into swing; Lester Young, Charles Parker, Dizzy Gillespie and Miles Davis represented advance-guard styles variously known as "bop" and "progressive." Noted among the arts as one of the most democratic, jazz was no longer chiefly the American Negroes' but was the national music, and because of its international popularity was one of the U.S. department of state's most valuable art forms for overseas presentations.

5. Art.—In painting, several Negroes were outstanding. Henry O. Tanner's pictures were winning medals as early as 1900, and by mid-century many of them were in the leading galleries of the United States and Europe. After World War I, Aaron Douglas received recognition for his black-and-white drawings and illustrations. Laura Wheeler Waring painted scenes from life among upper-class Negroes while Edward A. Harleston confined himself to genre painting. Later, Hale Woodruff, Romare Bearden and Charles Alston of New York city and James Porter and Lois Jones of Washington, D.C., proved to be careful observers as well as skilled and versatile artists. One of the most widely acclaimed artists was Jacob Lawrence, whose rigorously modernistic paintings concentrated on Negro history and experience. E. Simms Campbell and Ollie Harrington were illustrators and socially penetrating caricaturists. In the field of sculpture, Meta Warrick Fuller won recognition before World War I and continued to do significant work thereafter. Elizabeth Prophet and Augusta Savage executed pieces that reflected the successful use of Negro subjects in this difficult medium. Sargent Johnson also enjoyed success as a sculptor. Richmond Barthé became the foremost Negro sculptor in the United States and was commissioned to do the bust of Booker T. Washington for the Hall of Fame at New York university.

6. Science, Law and the Social Sciences.—In the sciences the best-known Negroes were George Washington Carver, chem urgist; Percy Julian, chemist; E. E. Just, biologist; Elmer Imes physicist; and Daniel Williams, William A. Hinton and Charle Drew in the medical sciences. Many Negro college teachers o science were dedicated to both teaching and research. Many phy sicians and surgeons by passing their specialty boards earned th title of diplomate; some were at long last admitted to local medi cal societies. Negro lawyers, especially Charles Houston, Thur good Marshall, James M. Nabrit, Jr., and Constance Motley, wer prominent in winning key civil rights cases; William Hastie an Thurgood Marshall were circuit court judges and other Negroe were on district, state and municipal benches. Significant contri butions to legal literature have been written by Charles Quick William Robert Ming and Dorsey Lane. In spite of the prove competence and services of Negro lawyers, the American Bar as sociation and some local associations were even slower than th medical societies in admitting Negroes. In the social science Charles S. Johnson, E. Franklin Frazier and W. Allison Davi gained national and international reputations with their sociologi cal studies; Abram L. Harris, William Dean, Clinton Knox an Robert C. Weaver were noted as economists; Carter G. Woodson John Hope Franklin, Rayford W. Logan and Benjamin Quarle were well-known historians. The outstanding Negro politica scientist at mid-20th century was Ralph J. Bunche, whose work a a United Nations mediator won for him the Nobel peace prize fo 1950. As undersecretary for political affairs to Secretary Genera U Thant, he was the chief United Nations authority in the nego tiations concerning the Katangan secession in 1963.

In education and public service the outstanding Negro woman of her generation was Mary McLeod Bethune (1875–1955), president for many years of Bethune-Cookman college at Daytona Beach, Fla.

MARY MCLEOD BETHUNE

7. International Relations.—Interest in Africa had been shown by American Negroes since the colonization ventures of the 19th century and Pan Africanism had engaged the attention of Negroes since the beginning of the 20th century. Several African leaders, notably Kwame Nkrumah of Ghana, Nnamdi Azikiwe of Nigeria and Hastings Banda of Nyasaland, were educated in the United States. After Ghana won its independence in 1957, American Negroes becam more and more involved in the struggles and achievements Africa; several Negro scholars were counted among the rapid growing number of American Africanists. The American Societ of African Culture, organized by Negro scholars and writers, he conferences and symposia, and published reports. The visits the United States of the presidents, prime ministers and oth leaders of the new African nations, and the dignified respect a corded to them by U.S. officers of state, gave many Negro Ame icans a sense of pride they had not previously known. Mo African students appeared on the campuses of American college

Many American Negroes were employed in various capaciti by African, Asian and South American nations; others were e ployed by private concerns, and still others held U.S. governme posts. Among the latter were three Negro ambassadors: Clift Wharton, ambassador to Norway; Carl T. Rowan, ambassador Finland for a time; and Mercer Cook, who was appointed amb sador to Senegal after having served as ambassador to Nig There were also a few Negro consuls and other foreign serv officers. Although such employment indicated that the policy the department of state was becoming less discriminatory in t recruitment and employment of American Negroes, the first Am ican Negro leadership conference held in 1962 at Arden Hou Harriman, N.Y., called upon the department of state to liberal

this policy further. Carl T. Rowan was head of the U.S. Information agency from Feb. 1964 to July 1965.

VIII. CONCLUSION

On Jan. 1, 1863, Abraham Lincoln signed the Emancipation Proclamation. Even this incomplete liberation was viewed with misgivings and forebodings by some, and hosannas and dreams by others. A century later neither the direst prophecies nor the rosiest dreams had come true. The struggle for first-class citizenship had been arduous. The Negro was aided in the struggle by white men of good will and democratic belief; to it he brought his own courage, stoicism, ambition, intelligence and foresight. His attainment of liberty and equality was not yet complete, his citizenship not yet first-class, but his progress had been strong and sure, and his saga one of the high points of American history.

(J. H. FN.; R. W. LN.; S. A. BR.)

NEGRO RIVER (Río NEGRO), one of the principal tributaries of the Amazon (*q.v.*), 1,056 mi. long. Its principal headwater affluents, the Vaupés (Uaupés) and the Guainía, rise in the rain forest of eastern Colombia. After turning southward the latter forms the Venezuela-Colombia border for more than 100 mi., becoming the Negro where it joins the Casiaquiare canal at San Carlos. Manaus, regional capital of the Amazon valley and a port for ocean-going vessels, is located on the high left bank of the Negro 12 mi. above its junction with the Solimões or Amazon. Near Manaus the Negro is an island-free estuary 4 mi. wide and at least 100 ft. deep, but farther upstream it is up to 20 mi. wide and filled with a labyrinth of lenticular islands formed by deposits of materials derived from its silt-laden, left-bank tributaries.

The clear, jet-black water of the Negro, from which it derives its name, contrasts dramatically with the yellowish, silt-laden water of its major tributary, the Río Branco, and with that of the Amazon. As it carries no sediment in its lower course the Negro has no flood plain. The low marginal areas (*igapós*), which its waters cover during much of the year, are forest covered. Dissolving humic acid, from the decomposition of organic matter in the soils of these swamps, gives the Negro its black colour.

Most of the drainage area of the Negro is of subdued relief, interrupted by occasional monadnocks reaching from 300 to 1,200 ft. above the forested plain. Through that strange natural waterway, the Casiaquiare canal, the Negro appears to be capturing the headwaters of the Orinoco system. (Js. J. P.)

NEGROS OCCIDENTAL, a province on the western and northern sides of Negros Island, Republic of the Philippines, facing the Island of Panay across Guimaras strait. Area 3,058 sq.mi.; pop. (1960) 1,332,323. The province has a large coastal plain built from sediments eroded from the igneous mountain mass in the interior.

The northern and northeastern portions of the province are less level, with rolling hills; the southern end is part of a grassy plateau that is shared with Negros Oriental. Mt. Canlaon (8,035 ft.) is an impressive volcanic peak near the centre of the island and Mt. Maldalgan (6,165 ft.) is the principal mountain in the north. Negros Occidental is the wealthiest province in the republic and probably the province with the greatest political influence in the national government.

Negros Occidental produces between 55% and 60% of the Philippine commercial sugar. There are ten modern *centrals* (mills for making raw sugar out of cane): Binalbagan, Victorias, La Carlota, Hawaiian-Philippine (near Saravia), Talisay-Silay, Ma-ao, Bacolod-Murcia, San Carlos, Lopez (at Sagay) and Danao (near Escalante). There is a large modern lumber mill at Fabrica, but the workable forests in that area have been largely exhausted. Other crops include coconuts, rice and corn (maize). There is a minor coal deposit near Escalante.

Bacolod, the capital and principal urban settlement, is a regional commercial centre and in the 1960s it was beginning to rival Cebu and Iloilo as a centre of political influence in the Visayans. Pop. (1960) 119,315. *See* BACOLOD, CITY OF. (AN. C.)

NEGROS ORIENTAL, a province on the eastern and southern sides of Negros Island, Republic of the Philippines. Area 2,217 sq.mi.; pop. (1960) 597,761. Peopled principally by Cebuanos and separated from the nearby island of Cebu by narrow Tañon strait, it is more closely related to Cebu both culturally and commercially than to the other side of Negros, from which it is separated by a rugged mountainous core of volcanic origin. The southern part of the province is principally a grassy plateau and is sparsely populated. The eastern portion grades from a discontinuous coastal plain into rolling limestone hills and then into forested mountain slopes. The principal crops are corn (maize), rice, sugar cane and coconuts.

Dumaguete city (pop. [1960] 10,528), the capital, is a minor regional centre with regular air service. It is a port of call for both interisland ships and ocean freighters. The community is probably best known as the site of Silliman university, a mission school with an excellent liberal arts college.

Siquijor Island (130 sq.mi.), a subprovince of Negros Oriental, lies directly opposite Dumaguete. Bais, 25 mi. N. of Dumaguete, is the site of a large sugar *central* (mill), the only one in the province, with a distillery for converting the by-product molasses into

industrial alcohol and a paper mill using bagasse (sugar-cane fibres) as its raw material. Other municipalities are Tanjay, Guihulñgan, Calamba, Zamboanguita and Siaton. (AN. C.)

NEHEMIAH (in the Douai version of the Bible, NEHEMIAS), governor of Judaea under Artaxerxes (*q.v.*), who was generally thought to be Artaxerxes I (465–424), although he could possibly have been Artaxerxes II (404–359 B.C.). The book of Nehemiah (II Esdras in the Douai version) forms the concluding portion of the great compilation Chronicles–Ezra–Nehemiah. Nehemiah's own account, written after 432 in the first person and confined to ch. i–iv, is the only authentic information which remains in regard to his life and work.

NEHRU, JAWAHARLAL (1889–1964), the first prime minister of independent India, was born in Allahabad on Nov. 14, 1889, of a prosperous Brahman family from Kashmir which had migrated to India early in the 18th century. His father, Motilal, was a highly successful and cultivated lawyer, with a house which contained a numerous family of cousins and a procession of guests, many of them English. Jawaharlal grew up with English governesses and tutors, one of whom, an Irish theosophist, Frederick T. Brooks, had considerable influence on his developing taste for poetry and science. When he was 16, he was sent to school at Harrow, Middlesex, Eng., and remained in England for more than seven years. These were divided between Harrow and Cambridge (where he took a degree in natural science), with two subsequent years at the Inner Temple in London. When he obtained his law degree in the summer of 1912, he was widely though not deeply acquainted with the culture of the time and had been influenced by Fabian socialism, the Irish Home Rule movement and the arguments for women's suffrage. He also had made some acquaintance with the European continent. His interest in Indian affairs had been only sporadically aroused at Cambridge by the news from home as debated by other Indian students there.

NEHRU

The Indian National Congress, which he attended on his return to India in 1912, was still an annual assembly of moderate, upper-class Indians speaking the English of the law courts. Their striped trousers and frock coats startled him. Jawaharlal found no appeal to his sensitive but fiery temperament in their measured discussions, nor could he feel at ease in the atmosphere of the law courts. His intellectual development owed more to his rapidly growing companionship with his own father, Motilal, although the elder Nehru was at this time by no means ready for the bold courses Jawaharlal's instinct already had suggested.

They both became aware at this period (1912–14) of M. K. Gandhi (*q.v.*) because of the success his method of voluntary sacrifice (*satyagraha*) was obtaining in South Africa. Gandhi returned to India in 1915, just before the outbreak of World War I, but took little part in public affairs. Jawaharlal met him in Dec. 1916, at the Lucknow session of the National Congress, but found him "very remote." Successive *satyagraha* campaigns by Gandhi for specific purposes, such as the relief of the workers on indigo plantations in north Bihar, made his distinctive principles of collective action more familiar to the whole country thereafter. By the end of the war it was becoming apparent that the main political question in India would be, as it was for 30 years, what Gandhi was going to do next.

In 1919 the Rowlatt act, dealing with sedition, and Gandhi's reply in the form of a call to all Indians to stop work and fast in protest were followed by serious disturbances in the Punjab, particularly in Amritsar, where heavy casualties were caused when troops opened fire on a crowd at Jallianwalla Bagh. From then on the Nehrus, father and son, were firmly committed to the national movement and to Gandhi's leadership in it. The next Indian Congress met at Amritsar under Motilal Nehru's presidency (1920) but already the centre of moral authority had settled in Gandhi.

From then until the transfer of power from British to Indian hands (Aug. 15, 1947), the struggle for independence was nearly incessant, although subject to strange suspensions and interruptions, Nehru often thought, by the will of Gandhi. The relationship of these two strongly diverse yet mutually sympathetic men is one of the fascinating human dramas of the time. Nehru's mind could not accept the religious basis for many of Gandhi's decisions and the apparent lack of reasoning that led to them. Slowly he came to see that the Mahatma had a knack of being right in the end and, furthermore, that the Indian masses understood him and would have no other leader. Their frequent disagreements in the 1920s and 1930s seem to have made no difference to their loyalty and affection. Gandhi repeatedly said, "Jawahar is my political heir." On one occasion Nehru sent him a telegram of dissent from a decision taken, ending, "But who am I to argue with a magician?"

Nehru's father died in 1931, having been swept along by his son and Gandhi into a position far more extreme than he had been willing even to consider a few years before. Jawaharlal counted them both (his "two fathers") as supreme influences in his life, but he added also the influence of his lovely wife, Kamala, whom he married in 1916; she died in Switzerland of tuberculosis in 1936. Their only child, Indira, married to the late Feroze Gandhi, was to become president of the Indian National Congress in 1959, like her father and grandfather before her.

Nehru went to jail for the first time in 1921 in obedience to the Gandhian precepts, and was released for the last time in 1945, not long before he became prime minister. In all he spent almost 10 years in jail out of 27 years in the national movement.

The negotiations between British and Indian leaders that led to the transfer of power were conducted with Nehru as chief negotiator for the National Congress. When partition seemed inevitable, at least in preference to civil war, he accepted that, also. He became interim prime minister in 1946. At midnight on Aug. 14–15, 1947, the transfer was accomplished, and two new countries came into being, India and Pakistan. Thenceforward Nehru's biography merged with the history of contemporary India, of which it might be regarded as a decisive if not sovereign element.

Partition had dire results. Much public disorder and bloodshed brought on a mass exodus of Hindus from Pakistan and of Muslims from India. The refugee problem thus created was a primary claim on the energies of the new government and drained its resources for more than a decade. The princely states, once regarded as an insuperable obstacle to Indian unity, were unexpectedly amenable, and most of their rulers adhered to one or the other of the new nations without debate. Exceptions were Kashmir and Hyderabad, the first with a Hindu ruler over a predominantly Muslim state and the second with a Muslim ruler over a predominantly Hindu state. Faced with an invasion of Pathan tribesmen from the North-West Frontier Province, the maharaja of Kashmir acceded to the Indian union in Oct. 1947 and appealed to Nehru for help. Pakistan supported the tribesmen, and a vexatious conflict ensued, ending with virtual partition in the cease-fire of Jan. 1, 1950, with India occupying two-thirds of the state and Pakistan the rest. Hyderabad, after prolonged disorder, was occupied by military force in Sept. 1948 and acceded to the Indian union by treaty in the following year. All the states were subsequently reorganized with revised frontiers, the second time in accordance with predominant local languages, but by 1960 their divisive tendencies seemed curbed and their constitutional relation to the central government stabilized.

Nehru's part in the consolidation of the country was great, but after the crises of the early years were surmounted, his attention and energy were spent mainly upon two great concerns: domestically, on the successive Five Year plans, and, internationally, upon the evolution of a distinctive foreign policy aiming at friendship with all countries regardless of their systems and the preser-

vation of peace when possible. The assassination of Gandhi (Jan. 30, 1948) had by no means removed his influence, and Nehru was often quoted as saying the Mahatma was more powerful in death than in life. This was to be felt at every twist and turn of international affairs, where India consistently took positions governed by the nonviolent principle. Nehru's personal diplomacy involved state visits to the United States, the U.S.S.R. and Communist China, as well as his regular visits to England for commonwealth conferences; with all of these he managed to keep on good terms for the first decade. The ideal of coexistence between countries of different or opposing structures was put to the test in India's relations with China from 1953 to 1956 but was strained in that year by the Chinese pretensions in Tibet. In 1959, when China absorbed Tibet completely and the 14th dalai lama fled to India, the two Asian giants came to sharp disagreement and, at various points around the Tibetan border, into local hostilities. China's ethnic claims, arising from the theory that Tibet was an integral part of China, took in a part of northern India and the predominantly Buddhist border states of the Himalayas. There seemed little likelihood of a permanent settlement in the absence of any principle common to both sides, but in the teeth of much popular agitation Nehru characteristically continued to try. At the same time he repeatedly declared that India's frontiers would be defended against all comers.

His foreign policy was often criticized in Europe and the United States, and the word "neutralist" was applied to it. Nehru said that his policy was not neutralist but independent, claiming the prerogative of decision and judgment on each question as it arose. He voted for the U.S. resolution on Korea (1950) at the UN, and after the ensuing war he sent Indian troops to supervise the exchange of prisoners that made the armistice possible. He was quick to oppose the Anglo-French action at Suez (1956) but slow to condemn the subsequent Soviet action in Hungary, owing, he said, to lack of full information. His visits to all countries evoked popular demonstrations, and within a few years of independence Delhi had become a favourite resort of peace delegations and conferences of all sorts. The moral influence India acquired through Nehru's policy was displeasing at times to one side or the other in the "cold war," but its reality at the UN and throughout the world, particularly in Asia and Africa, was a recognized element in the international situation.

Nehru visited the UN in New York in 1960 (15th general assembly) and in Feb. 1961 supported its efforts in the Congo against a Soviet demand that they cease. He was even willing to send Indian combat troops there in the UN service, a remarkable departure from previous policy. Some observers saw indications of a pro-western evolution in this and other respects, perhaps related to India's difficulties with China. Nehru's precepts and definitions remained unchanged: India would participate in no military pacts and no other alignments or groupings except the British Commonwealth, with which, chiefly by his own efforts, the sovereign republic of India was freely associated after 1950.

As prime minister, Nehru showed skill and resilience in parliamentary debate, the ability to yield gracefully when necessary, and great respect for the speaker and the house. His vast power in India arose chiefly from his popularity with the masses. Thus he did not control either parliament or his own party by patronage and discipline, to which he was often indifferent, but by the fact that few could consistently oppose him and survive before the electorate. His gifts as a speaker were not for formal eloquence, although he could rise to it on occasion. Rather he seemed to talk as if he were thinking aloud and taking his audience into his confidence. In spite of the dangers of misquotation, he often spoke without a text or notes. This direct and familiar approach to the people, reminiscent of Gandhi's methods, was irresistible to the masses in India and, along with his services through many years, made the merest hint of his resignation or retirement a shock to the public and a signal for nationwide protest. He never believed it the part of a leader in democracy to dictate his own successor and died (May 27, 1964) without having done so.

Nehru received valuable support from his sister Vijaya Lakshmi Pandit, who had also been very active in the nationalist movement. She was leader of the Indian delegation to the UN general assembly, 1946–48; Indian ambassador to Moscow, 1947–49, and to Washington, 1949–51; president of the UN general assembly, 1953–54; and Indian high commissioner in London, 1954–61.

His writings include *An Autobiography*, third revised edition (1948); *Nehru on Gandhi* (1948); *The Discovery of India*, fourth edition (1956).

NEKRASOV, NIKOLAI ALEKSEEVICH (1821–1878), Russian poet and journalist, whose main theme was compassion for the sufferings of the peasantry, though he could also express the racy charm and vitality of peasant life in his adaptations of folk songs and poems for children. Born at Yuzvin, near Vinnitsa in the Ukraine, on Dec. 10 (new style; Nov. 28, old style), 1821, he was brought up in the government of Yaroslavl, where his father was a landowner. He studied at St. Petersburg university, but his father's refusal to help him forced him into literary and theatrical hack work at an early age. An able businessman, he published and edited literary miscellanies and in 1846 bought from Pëtr Pletnev the magazine *Sovremennik* ("The Contemporary"), which had declined after the death of its founder, Aleksandr Pushkin. Nekrasov managed to transform it into a major literary journal and a paying concern. Both Turgenev and Tolstoi published their early works in it, but after 1856, influenced by its subeditor, Nikolai Chernyshevski (*q.v.*), it began to develop into an organ of militant radicalism. It was suppressed in 1866, after the first attempt to assassinate Alexander II. But in 1868 Nekrasov, with Mikhail Saltykov (Shchedrin), took over *Otechestvenniye zapiski* ("Fatherland Annals"), remaining its editor and publisher until his death in St. Petersburg on Jan. 8, 1878 (N.S.; Dec. 27, 1877, O.S.).

Nekrasov's work is uneven through its lack of craftsmanship and polish and a tendency to sentimentalize his subjects, but his major poems have lasting power and originality of expression. *Moroz krasny-nos* (1863; Eng. trans., "Red-nosed Frost," in *Poems*, 1929) gives a vivid picture of a brave and sympathetic peasant woman, and his large-scale narrative poem, *Komu na Rusi zhit khorosho?* (1879; Eng. trans., *Who Can Be Happy and Free in Russia?*, 1917), shows to the full his gift for vigorous realistic satire. (R. HA.)

NEKTON, a Greek word meaning "swimming" and used in biology as the collective term for large free-swimming (rarely floating) aquatic animals. Nekton is distinguished from the drifting plankton (*q.v.*) and the bottom-dwelling benthos (*q.v.*). *See* MARINE BIOLOGY.

NELLORE, a town and district in Andhra Pradesh, India. The town, headquarters of the district, lies on the right bank of the Penner river, 95 mi. N. of Madras on the Southern railway. Pop. (1961) 106,776. It was made a municipality in 1866. The arts and science college, founded by the raja of Venkatagiri in 1876, and a Sanskrit college are both affiliated to Sri Venkateswara university at Tirupati. There are also seven high schools and three training schools. The American Baptist mission and the Roman Catholic mission started educational work in Nellore in the 19th century. The town is noted for the manufacture of ceramics. The national highway passing through the town is the main traffic route from Madras to Vijayavada.

NELLORE DISTRICT has an area of 7,974 sq.mi. Pop. (1961) 2,033,679. It comprises a tract of low-lying land extending from the Eastern Ghats to the sea. Its general aspect is forbidding: the coastline is a fringe of blown sand through which the waves occasionally break. Farther inland the land rises, but the soil is not naturally fertile. The chief rivers are the Penner, Kandaleru, Swarnamukhi, Musi, Paleru and Monneru. About 50% of the total area is cultivated, of which about half is irrigated. The dis-

trict is noted for mica mining and ceramic manufacturing. The chief crops are millets, rice and pulses. The local breed of cattle is well known. Nellore, with the rest of the Carnatic, passed under direct British administration in 1801. (B. S. R.)

NELSON, HORATIO NELSON, VISCOUNT (1758–1805), duke of Brontë in Sicily, British naval hero, was born at Burnham Thorpe, in Norfolk, on Sept. 29, 1758. His father, Edmund Nelson, was rector of the parish and his mother, Catherine Suckling, was related to Sir Robert Walpole (1st earl of Orford). His uncle, Capt. Maurice Suckling, later became comptroller of the navy.

Early Life.—Horatio Nelson, who was educated at Norwich, Downham and North Walsham, was entered in the "Raisonnable" when Captain Suckling was appointed to her in 1770 on an alarm of war with Spain. The dispute was settled and Captain Suckling was transferred to the "Triumph," the guardship at Chatham, taking his nephew with him. In order that the lad might have more practice than could be obtained in a harbour ship, his uncle sent him to the West Indies in a merchant vessel, and on his return gave him constant employment in boat work.

In 1773 Nelson served with Captain Lutwidge in the "Carcass," in an expedition to the arctic under the command of Captain Phipps (later Baron Mulgrave). On his return from the north he was sent to the East Indies in the "Seahorse," in which vessel he met his lifelong friend Thomas Troubridge. At the end of two years he was invalided home. In later times he spoke of the depression under which he laboured during the return voyage, until "after a long and gloomy reverie, in which I almost wished myself overboard, a sudden glow of patriotism was kindled within me, and presented my king and my country as my patron. My mind exulted in the idea. 'Well then,' I exclaimed, 'I will be a hero, and, confiding in Providence, I will brave every danger.'" He spoke to friends of the "radiant orb" which from that hour hung ever before him and "urged him onward to renown."

On his return he served during a short cruise in the "Worcester" frigate, passed his examination as lieutenant on April 9, 1777, and was confirmed in the rank next day. He went to the West Indies with Captain Locker in the "Lowestoff" frigate, was transferred to the flagship of Sir Peter Parker and was then promoted in rapid succession to the command of the "Badger" brig and the "Hinchinbrook" frigate. By the last appointment, which he received in 1779, he was placed at the age of 20 in the rank of post captain (from which promotion to flag rank was by seniority).

Active Service.—In 1780 Nelson saw arduous active service in an expedition to San Juan in Nicaragua; he became very ill with fever, and once more was invalided home. In 1781 he was appointed to the "Albemarle" frigate, and after some convoy service in the North sea and the Baltic, was sent to Newfoundland and then to the North American station. From there he sailed for the West Indies, where he made the acquaintance of Admiral Lord Hood. The admiral presented him to the duke of Clarence (afterward William IV), as an officer well qualified to instruct him in "naval tactics"—a marked compliment to a young officer from one of the greatest exponents of the art. He appeared, said the prince, "to be the merest boy of a captain I ever beheld; and his dress was worthy of attention. He had on a full-laced uniform; his lank unpowdered hair was tied in a stiff Hessian tail of an extraordinary length; the old-fashioned flaps of his waistcoat added to the general quaintness of his figure, and produced an appearance which particularly attracted my notice; for I had never seen anything like it before, nor could I imagine who he was or what he came about. My doubts were, however, removed when Lord Hood introduced me to him. There was something irresistibly pleasing in his address and conversation; and an enthusiasm, when speaking on professional subjects, that showed he was no common being." The slight oddity of appearance, the power to arouse affection, and the glow indicating the fire within, are noted by all who ever looked Nelson in the face.

PORTRAIT OF NELSON AS A CAPTAIN BY J. F. RIGAUD

The peace of Versailles (1783) gave Nelson leisure to visit France, and in 1784, when most naval officers were condemned to idleness on shore, he had the good fortune to be appointed to the command of the "Boreas" frigate, for service in the West Indies. While on that station he insisted on enforcing the navigation laws against the Americans, who by becoming independent had become foreigners. He called the attention of the government to the corruption prevailing in the dockyard of Antigua. His line impressed the admiralty as somewhat assuming, and his strong measures against the interloping trade brought on him lawsuits, which caused him much trouble.

In the West Indies on March 11, 1787, Nelson married Frances Nisbet, the widow of a doctor in Nevis. The union was one of affection and prudence.

Outbreak of War.—When war broke out with revolutionary France, Nelson was appointed captain of the 64-gun "Agamemnon," and joined his ship on Feb. 7, 1793. From this date until June 1800 he was engaged on almost continual active service. This period is the most varied, the busiest, the most glorious and the most debated of a very full career.

It subdivides naturally into three: (1) From the date of his appointment as captain of the "Agamemnon" until he was disabled by the loss of his arm in the unsuccessful attack on Santa Cruz de Tenerife on July 24, 1797, he served as captain or commodore, under successive commanders in chief in the Mediterranean. (2) After an interval of nine months spent at home in recovering from his wound, he returned to the Mediterranean and was at once sent in pursuit of the great French force which sailed from Toulon under the command of Napoleon for the conquest of Egypt. His victory of the Nile, on Aug. 1, 1798, placed him in the foremost rank among the warriors of a warlike time and made him a national hero. (3) From his return to Naples after the battle of the Nile until his return to England in the summer of 1800, he was immersed in Mediterranean affairs which tended to centre around the shores of Naples and Sicily.

The Mediterranean.—The first of these three passages in his life is full of events, which must, however, be told briefly. In June 1793 he sailed for the Mediterranean with Admiral Hood and was engaged under Hood's orders in the occupation of Toulon by the allied British and Spanish forces. In September he was dispatched to Naples to arrange for troops to contribute toward the garrison of Toulon. It was on this occasion that he made the acquaintance of Emma Hamilton (*q.v.*), the wife of Sir William Hamilton, minister at the court of Naples. References to Lady Hamilton begin to appear in his letters to his wife, but, as might be expected, they indicate little beyond respectful admiration, and he makes a good deal of her kindness to his stepson, Josiah Nisbet, whom he had taken to sea.

After the allies had been driven from Toulon, Nelson was mainly employed in the operations connected with the occupation of Corsica. In April and May 1794 he was engaged in the capture of Bastia; in June, July and part of August in the taking of Calvi. During the operations at Calvi, Nelson received a wound in his right eye which healed without leaving disfigurement, though the sight faded. From the date of the occupation of Corsica until the island was evacuated (1794–96) he was incessantly active. He served under William (later Baron) Hotham, who succeeded Hood in the command, and was engaged in the indecisive actions fought by Hotham in March and July 1795. The complacency of the new admiral fretted the eager spirit of Nelson, who declared that, for his part, he would never think that the British fleet had done well if a single ship of the enemy escaped while there was a possibility of taking her. Happily he was detached to the Riviera of Genoa, where, first as captain and then as commodore, he had scope and opportunity to prove his qualities for independent command by

harassing the communications of the French and co-operating with the Austrians.

In Sir John Jervis, who superseded Hotham, he found a leader after his own heart. When Spain, after first making peace with France, declared war on England, and the fleet under Jervis withdrew from the Mediterranean, Nelson was dispatched to Elba on a hazardous mission to bring off the small garrison and the naval stores. He sailed in the "Minerve" frigate, having another with him. After a smart action with two Spanish frigates and a narrow escape from a squadron of Spanish line-of-battle ships, he fulfilled his task and rejoined the flag of Jervis on the eve of the great battle (Feb. 14, 1797) off Cape St. Vincent. (*See* SAINT VINCENT, BATTLE OF.) The judgment, independence and promptitude he showed in this famous engagement revealed him as one of the heroes of the navy.

NELSON RECEIVING THE SURRENDER OF THE "SAN JOSEF," FEB. 14, 1797. OIL PAINTING BY RICHARD WESTALL

Blockade of Cádiz.—A few days after the victory Nelson became rear admiral by seniority, but continued with Jervis, who was made a peer under the title of earl of St. Vincent. Nelson's own services were recognized by his being made a knight of the Bath. During the trying months in which discontent in the fleet was developing toward the mutinies at Spithead and the Nore, he remained with the flag and in the blockade of Cádiz.

In July 1797 he was sent to Santa Cruz de Tenerife and made a desperate attempt to capture it. The enterprise was, in fact, rash in the last degree, for no troops were available for the service, and a fortified town was to be taken by man-of-war boats alone. The Spaniards were on the alert and the attack, made with the utmost daring on the night of July 24, was repulsed with heavy loss. Some of the boats missed the mole in the dark and were stove in by the surf, others being shattered by the fire of the Spaniards. Nelson's right elbow was shot through and he fell back into the boat from which he was directing the attack. The amputation of his arm was performed in haste and in semi-darkness. He was invalided home and spent months of pain in London and at Bath. In April 1798 he returned to the fleet off Cádiz as rear admiral, with his flag in the 74-gun "Vanguard."

Nelson was then one of the most distinguished officers in the navy. Within the next six months he was to raise himself far above the heads of his contemporaries. A great armament was preparing at Toulon for some unknown destination. To discover its purpose, and to defeat it, the British government resolved to send a naval force into the Mediterranean, and Nelson was chosen for the command.

Command in the Mediterranean.—Having joined the flag of Lord St. Vincent outside the straits of Gibraltar on April 30, Nelson was detached on May 2, with three line-of-battle ships and five frigates, to discover the aim of the Toulon armament. Napoleon had, however, enforced rigid secrecy, and beyond the fact that a powerful combined force was collected in the French port, Nelson could learn nothing. On May 20 the "Vanguard" was dismasted in a gale. "I ought not," wrote Nelson, "to call what has happened by the cold name of accident; but I believe firmly that it was the Almighty's goodness to check my consummate vanity." The "Vanguard" was saved from going on shore by the skill of Captain Ball of the "Alexander," for whom Nelson had henceforth a peculiar regard.

The frigates attached to his command had returned to Gibraltar, in the erroneous belief that the big ships would be taken there to make good the damage suffered in the gale. In June Nelson was off Toulon again, only to find that the French were gone. Deprived of his best means of obtaining information by the disappearance of his frigates, he remained cruising until he was joined by Captain Troubridge with ten sail of the line. He then started on his fierce pursuit of the enemy, seeking him in the dark, for there were no scouts at hand; exasperated at being left without the eyes of his fleet; knowing that St. Vincent would be blamed for choosing so young an admiral; but resolved to follow the enemy to the antipodes if necessary. From Sardinia to Naples, from Naples to Messina, from Messina to Alexandria, from Alexandria, where he found the roadstead empty, back to Sicily and then, when at last a ray of light came to him, back to Alexandria—he swept the central and eastern Mediterranean.

Unlike most admirals of his time, he freely discussed his plans with his captains. He had his reward in their devotion and perfect comprehension of what he wished them to do. At the same time he acquired an absolute confidence in the efficiency of his squadron, the magnificent force which had been formed by years of successful war and by the careful training of his predecessors. The captains were the band of brothers he himself had made them.

The great victory of Aug. 1, 1798 (*see* NILE, BATTLE OF THE), brought Nelson yet another wound. He was struck on the forehead by a shot and had for a time to go below. For this victory he was made a baron.

Blockade of Naples.—After providing for the blockade of what remained of the French in Alexandria, Nelson set sail for Naples and arrived there on Sept. 22. Pitt's second coalition against France was then on the point of completion, and Naples, naturally enough in view of the French behaviour on its borders, was preparing to side with Austria and Russia in the defense of monarchy; indeed Naples was already organizing an army, but no decision as to how the troops should be used had as yet been arrived at. Nelson immediately tried to enliven the proceedings and suggested what should have been a perfectly feasible plan, by which the Neapolitan army was to advance northward against the French front, while the fleet was to capture Leghorn, thus cutting the French communications.

Leghorn was duly taken, but the army showed little aptitude for fighting, soon becoming a disorderly rout, pursued by the French. This had the effect of rousing all the Jacobins in the country, which was soon in such an uproar that the royal family found it necessary to retreat to Palermo—an evacuation carried out by Nelson and his ships. From Palermo, Nelson kept up a double blockade—one squadron under Captain Ball was detached to Malta and another, under Captain Troubridge, was sent to the bay of Naples to operate against the Neapolitan Jacobins.

The king and queen, however, found this method of pressure

too slow, and determined to appeal to the conservative instincts of many of their subjects through the agency of an ecclesiastic, Fabrizio Cardinal Ruffo. Ruffo landed in Italy, and his appeal for an "Army of the Faith" was soon answered by thousands. While these events were taking place, a French fleet of 26 vessels, under Admiral Bruix, set out from Brest and was joined by 17 Spanish warships at Cartagena. Such a force constituted a threat to Nelson, who called up his ships from Malta and Naples and prepared for resistance. He managed, however—and this was important in view of Ruffo's successful beginning—to maintain the blockade of Naples by means of a squadron of small ships placed under Captain Foote.

The Franco-Spanish threat proved an idle one and the allied fleet soon retired, but, in the meanwhile, Ruffo was driving all before him and finally shut up the French in the castle of St. Elmo, in the city of Naples, and the native insurgents in the sea-washed castles of Uovo and Nuovo. From this commanding position he began to parley with the enemy, and the king, hearing of this, and nervous of what the cardinal might do—he had not been empowered to make terms of peace—asked Nelson to proceed to Naples and take matters into his own hands.

Ruffo's Treaty of Peace.—Nelson sailed for Naples, with Sir William and Lady Hamilton on board, on June 21, and arrived on the 24th to find the white flag flying from the castles and from his own flotilla. Supposing this to indicate an armistice, he at once made signal for the resumption of hostilities, only to be informed by Captain Foote that matters had gone further and that a treaty of peace had been signed by which the native insurgents were to be allowed to leave their strongholds with all the honours of war and were to be carried by ship to countries that would be willing to receive them.

In making such a treaty there can be no doubt that Ruffo had exceeded his instructions, though it is probable that he was actuated by motives of humanity, since his control over his bloodthirsty army was incomplete. Nelson refused to listen to Ruffo's arguments or to admit the validity of his undertakings. He agreed to let the armistice run its course, but let it be known that at the end of it he would expect unconditional surrender. This he received, and the rebels were placed in boats. One, Carraciolo, reached the hills, only to be caught at last and brought to Ruffo. He in his turn, because Carraciolo was a naval officer, handed him over to Nelson, who at once convened a court-martial of Neapolitan officers to try the rebel. The court sentenced Carraciolo to death by a majority vote, and this sentence was immediately carried out.

For refusing to carry into effect Ruffo's peace terms and for not interfering to delay the execution of Carraciolo, Nelson has been violently attacked. The whole matter is too involved to be fully discussed here; the conclusions which have been reached by scholars on either side have almost invariably reflected the political prejudice of the writers.

The whole question of Nelson's conduct at Naples is of course bound up with his friendship with Lady Hamilton. No one denies that it was then that Nelson's friendship for this woman ripened into the intimacy that was eventually to separate him from his wife. But that a private attachment seriously warped his judgment in public matters no one has yet shown, nor has anyone explained why it should.

Return to England.—These events were shortly followed by the reduction of the French and by the restoration of the Neapolitan royal family, while in the same month Nelson laid himself open to a sharp rebuke from the admiralty for disobeying the orders of Lord Keith, who had been appointed to succeed Lord St. Vincent in the Mediterranean command. Keith, puzzled as to the objective of a combined Franco-Spanish fleet, decided that Minorca was in danger and ordered Nelson to its defense. Nelson decided that it was not in danger and did not go. His judgment was correct, but his disobedience was inexcusable.

On Jan. 20, 1800, having in the meantime been created duke of Brontë by the king of Naples, Nelson joined Keith at Leghorn, and in February captured "Le Généreux," which had escaped him at the Nile. Shortly afterward he obtained leave to go home and, not being spared a battleship, he traveled overland with Sir William and Lady Hamilton, being fêted on the way. He landed in England in November of the same year.

Battle of Copenhagen.—Nelson's leave, which promoted the final separation between him and his wife, was short. He became vice-admiral on Jan. 1, 1801, and soon after was offered the post of second in command to Sir Hyde Parker in the fleet which was to break up the armed neutrality of the northern powers. It is difficult to see why such a brilliant man was subordinated to one of such ordinary gifts as Parker. Nelson, however, treated Parker with such tact that the admiral's reserve toward him disappeared. Indeed Nelson had his commander in chief to some extent under his thumb by the time they reached Copenhagen, and so was permitted to carry out his famous attack on the city and its defenses that resulted in the battle of Copenhagen (*q.v.*). This battle showed Nelson's ability to hit upon the weak point in a defensive scheme and is famous for his action in putting his telescope to his blind eye when, in the middle of the fight, his attention was directed to Parker's signal ordering his withdrawal. It was an order that could not be obeyed without losing all chance of decision.

In May, Parker was recalled and Nelson given the command, but the armed neutrality was dissolved and this left him little to do. His health, too, was bad and in June he went home, his services having been recognized by the bestowal of the title of viscount. In the months before the peace of Amiens he was in command of a flotilla of small ships that were to combat Napoleon's threat of invasion. More in the hope of satisfying public opinion than for any other reason, an attack was launched on Boulogne with the object of destroying the flat-bottomed boats stationed there. The port, however, was too strongly defended even for a Nelson.

During the short period of the peace of Amiens (1802–03), Nelson, in company with Sir William and Lady Hamilton, lived at the house and estate that he had purchased at Merton in Surrey. This, probably the happiest period of his life, was all too short. War reopened in May 1803, and Nelson was at once appointed to the Mediterranean command.

The Mediterranean Command, 1803.—Nelson arrived off Toulon in July 1803 and instituted a strict blockade of that port. The French under Latouche-Tréville continually tried to lure him into indecisive actions in which, by damaging some of his ships they might force him to withdraw, but Nelson consistently refused such offers and the French admiral, writing to Napoleon, stated that he had offered battle but the English had withdrawn. Nelson declared that if he captured Tréville he would make him eat the letter, but he never had the chance to fulfill his boast, even figuratively, for Tréville died and was succeeded by Villeneuve.

In the spring of 1805 the French eluded the blockade and made for the West Indies. This move was part of a large scheme directed toward the invasion of England. The series of naval movements arising from it are known as the Trafalgar campaign, and the whole matter is dealt with under NAPOLEONIC WARS. Nelson, after searching the Mediterranean, decided that Villeneuve had gone to the West Indies, and thither he followed him. On hearing of his enemy's arrival, Villeneuve returned precipitately to Europe, again pursued by Nelson, and got into El Ferrol and then into Cadíz where he was blockaded by Collingwood.

Nelson meanwhile had gone home on leave to enjoy the delights of Merton. His respite was brief. No sooner had the news reached England that the allied fleet was in Cadíz than, with the approval of Lady Hamilton, he offered his services, "to give M. Villeneuve a drubbing." They were immediately accepted, and he left Merton for the last time on Sept. 13, and on the 28th was off to Cadíz.

Trafalgar.—The victory of Trafalgar (*q.v.*) which followed on Oct. 21 set the seal on Nelson's fame. Tactically it was a masterpiece, and his famous signal "England expects that every man will do his duty," made as the fleet moved into battle, together with his death in the moment of victory, added, and still add, to its lustre.

The "Victory," after passing through the French line, was ex-

gaged with the "Bucentaure" and the "Redoubtable," and Nelson, as he walked up and down his quarterdeck with his flag captain, Thomas Hardy, was struck by a bullet from a sharpshooter firing from the top of the "Redoubtable." His spine was broken and he was carried below to the cockpit, suffering great pain. There, amid the din and racket of battle, he lingered for a few hours. To the last he retained his interest in the battle, and Hardy came to him from time to time to tell him of its progress. As his sight grew dimmer and he felt the end approaching he asked Hardy to kiss him. "Now I am satisfied," he said, "Thank God I have done my duty."

THE "VICTORY," NELSON'S FLAGSHIP, MOORED AT PORTSMOUTH, ENG.

Nelson's body was taken home and buried in St. Paul's.

So died the most famous of English seamen. He was more than merely a tactically brilliant commander; he was a true leader of men—and men of all types, for the common seamen trusted and venerated him as much as did his officers. The seamen were, in their turn, trusted by him and were ever in his confidence. No officer under Nelson could ever complain that he went into action not knowing his commander's plans and intentions—and it is as much to this as to his tactical ability that his successes were due. It has been said that he was vain, liked flattery and was an egotist. In fact, he had faults common in genius.

(D. H.; O. M. W. W.)

NELSON, a municipal borough (1890) in the Nelson and Colne parliamentary division of Lancashire, Eng., 28 mi. N. of Manchester by road. Pop. (1961) 32,292. The area of Marsden was entirely agricultural until the 18th century when a small wool factory was established from which developed the present industrial town specializing in silk and cotton weaving. The coming of the railway caused the change of name from Marsden to Nelson (after the Lord Nelson inn) to avoid confusion with Marsden in Yorkshire.

NELSON, a town on the northern coast of the South Island, New Zealand. It is the administrative and commercial centre of the Nelson land district and Tasman Bay lowland. Pop. (1961) 23,971 (urban area 25,321). Its mild climate is the sunniest in New Zealand and it is the centre of an intensive fruit- and vegetable-growing area. Its industries reflect this, and are largely concerned with canning and preserving. Nelson is linked with Wellington, Christchurch and Westland by air services. The settlement was established by the New Zealand company in 1842.

Nelson Land District had a population of 74,281 at the 1961 census. Area 10,870 sq.mi. It occupies the northwest corner of the South Island west of the St. Arnaud and Spenser mountains as far south as Punakaiki and the upper Grey river. It is a rugged and empty portion of the country. Population is largely confined to: (1) the mild and sunny Tasman bay lowland where an intensive crop-growing economy (tobacco, hops, apples, soft fruit, tomatoes) is serviced by Nelson and Motueka (pop. 3,310); (2) the Buller, New Zealand's only bituminous coalfield (Granity, Stockton, Millerton and Denniston). Westport (pop. 5,464) is the chief town of this section. In the southeast corner of the district Nelson Lakes National park (214 sq.mi.) contains the beautiful lakes Rotoiti and Rotoroa, and rises to Mt. Franklyn (7,636 ft.). (K. B. C.)

NELSON RIVER, in Manitoba, Can., drains the waters of Lake Winnipeg and discharges into Hudson bay near Port Nelson, 400 mi. to the northeast, falling 713 ft. in the process. The catchment area of Lake Winnipeg extends from the Rocky mountains to Minnesota, so that the Nelson has a total drainage basin of 444,000 sq.mi. and includes the North and South Saskatchewan rivers, the Assiniboine and the Red River of the North. The total length of the Nelson from its source at the head of the Bow River in the Rockies is 1,600 mi. Its chief tributary is the Burntwood. The Nelson was discovered in 1612 by Sir Thomas Button and named for another member of the expedition. Norway House, at the source of the Nelson, is a Hudson's Bay company trading post and York Factory, near its mouth, operated as a trading post from 1682 to 1957. The Nelson is navigable for about 56 mi. from its mouth. Power development along the river is under the control of the Manitoba Hydro-Electric board. (An. Kr.)

NEMAN (Lithuanian Nemunas; German Memel; Polish Niemen), a river of the western U.S.S.R., is 582 mi. long and drains a basin of about 38,000 sq.mi. It rises 30 mi. S.W. of Minsk, on the southern flank of the Minsk upland (Minskaya Vozvyshennost) in the Belorussian Soviet Socialist Republic. Cutting through the Belorussian ridge (Belorusskaya Gryada) the Neman flows in a general westerly direction, across a broad basin, often extremely swampy. Near Grodno it swings northward into the Lithuanian S.S.R., cutting through another belt of terminal moraines. The valley there is much narrower and highly sinuous. Just above Kaunas the Neman turns west once more and, flowing across another broad, marshy basin, between Lithuania and Kaliningrad *oblast,* past Sovetsk (formerly Tilsit), it enters the Kurski gulf (Kurisches Haff) of the Baltic. Its main tributaries are the Viliya, on which Vilnius stands, the Shchara, Merkis and Nevezis. Navigation for small craft extends to Belitsa village, about 416 mi. upstream. Considerable quantities of timber are rafted along the river. The Oginski canal, built at the end of the 18th century, formerly linked the Neman, by way of the Shchara, to the Pripyat (Pripet) and Dnieper, but it is now completely disused. The Neman has an annual average discharge of 24,367 cu.ft. per second, with a marked spring maximum. The average period of freeze-up is from late November to mid-March. There is a hydroelectric plant near Kaunas. (R. A. F.)

NEMATODA, class or phylum name for the roundworms (*q.v.*), marine, freshwater and soil forms, many of which are parasites of plants and animals, including man.

NEMATOMORPHA (Gordiacea), a class of elongate, threadlike, unsegmented worms belonging to the phylum Aschelminthes, which phylum includes also the roundworms (class Nematoda), rotifers (class Rotifera) and other mostly small to microscopic animals. Nematomorphs—called gordian worms, after their tendency to tangle together in loose writhing masses or knots, and horsehair worms, after the myth dating to the 14th century that these hairlike forms are transformed horsehairs—vary in length from a few inches to two or three feet, and in diameter from about $\frac{1}{100}$ inch to about $\frac{1}{16}$ inch. The free-living adults are often seen wriggling in quiet, shallow fresh waters throughout the world—ponds, streams, rain puddles and water troughs (occasionally in wet soil)—where they are indeed suggestive of horsehairs come to life. They vary in colour from buff or yellowish through shades of brown to black; the tip of the head end is almost always whitish bordered by a dark ring. The larvae are parasites of arthropods, chiefly insects.

The body wall consists of: (1) a stout cuticle, with an outer layer (smooth, or rough with minute nipples [areolas] sometimes bearing spines or bristles) and an inner layer of obliquely crossed fibres; (2) a single subcuticular layer of cells; and (3) a layer of longitudinal muscle fibres. Most of the space within the body wall is filled with soft, jellylike connective tissue (parenchyma) in which the internal organs are embedded. The alimentary canal is more or less degenerate in all horsehair worms; in most cases there is no mouth, so that active taking in of food at any time seems improbable. Instead, nutriment is absorbed through the skin and only when the immature nematomorph has become established in a host. What there is of an intestine opens along with the genital ducts into a common posterior chamber (cloaca). No circulatory or excretory organs are known. There is a single ventral

nerve cord, with anterior and posterior ganglia.

The sexes are separate, the males being usually smaller than the females and in some genera distinguishable by having a forked tail. The tail of the female is usually undivided, but in *Paragordius* it has three prongs. The gonads are paired in both sexes, and are continuous with their ducts.

Upon emergence from their insect hosts, usually in spring or early summer, they are sexually mature and copulation and egg-laying occur. In the pregnant female the ovaries give off thin-walled lateral pockets, which ultimately break down and discharge the ova into spaces in the parenchyma. The eggs, held together by a cementlike substance, are laid in strings or masses, usually on plants or stones under water. The first larval stage is a minute creature armed with spines and having a boring organ anteriorly, by means of which it enters the flesh of almost any aquatic animal; it must, however, find an appropriate host before it can fully develop. In species that attack insects such as grasshoppers, the second larval stage may apparently be reached without change of host. In others it may develop in a second host, usually a beetle, which preys upon the first. The second larval stage is elongate and wormlike, and develops directly into the adult form. Pigment is developed, and the larval cuticle shed, just before emergence from the host. This usually takes place on contact with water, the worm bursting its way out through a soft place in the host's body wall.

HORSEHAIR WORMS (MAGNIFIED): (A) ABDOMEN OF A BEETLE WITH BACK COVERING REMOVED, SHOWING WORM WITHIN; (B) FEMALE DEPOSITING ITS EGGS ON A WATER PLANT

The Nematomorpha includes two orders, Gordioidea and Nectonematoidea. The main genera of the former are *Gordius*, *Paragordius*, *Chordodes*, *Parachordodes* and *Gordionus*. Nectonematoidea comprises only one genus *Nectonema*, a form provided with rows of bristles and inhabiting the open ocean (pelagic).

NEMEA, BATTLE OF. This battle was fought in 394 B.C. in the valley of the Nemea river in the northern Argolid (near the modern town of Nemea) during the Corinthian War, which was waged against Sparta by a coalition of Thebes, Corinth, Athens and Argos, but instigated by Persia (*see* GREECE: *History: The City States, 404–354*). The coalition forces outnumbered those of the Spartans. As the lines advanced, the drift to the right characteristic of hoplite (*q.v.*) warfare occurred so that each right wing overlapped the opponents' left wing, the Spartans encircling the Athenians while their allies were overwhelmed by the Argives and Corinthians. The Spartans then wheeled round from attacking the Athenians and caught in succession the Argives, Corinthians and the Thebans in the flank as they returned from pursuing the Spartan allies.

Their opponents had heavier losses than the Spartans and the Spartan superiority in hoplite warfare displayed on this occasion broke the force of the coalition.

See Xenophon, *Hellenica*, iv, 2, 9–23.

NEMERTINA (NEMERTEA): *see* RIBBON WORM.

NEMESIANUS, MARCUS AURELIUS OLYMPIUS (fl. *c.* A.D. 280), Roman poet, born in Carthage, who wrote pastoral and didactic poetry. There survive four eclogues and an incomplete poem of 325 hexameters on hunting (*Cynegetica*). Two small fragments on bird catching (*De aucupio*) are generally attributed to him. The four eclogues were usually printed along with the seven eclogues of Calpurnius Siculus (*q.v.*); in 1854 M. Haupt established the difference of authorship and date. They are in the Vergilian tradition, influenced also by Calpurnius, purely imitative and of conventional form and imagery, and yet attractive because of their smooth diction and melodious movement. The *Cynegetica* gives instruction about dogs, horses and hunting equipment; it is a gracefully written piece in the literary genre of the *Georgics* and of the *Cynegetica* of Grattius.

NEMESIS, in classical mythology, the name of two divine conceptions. The first is a goddess, worshiped at Rhamnus in Attica, who is very similar to Artemis, of whom she may have been a local form; she may have had to do with fertility. In post-Homeric story she is pursued by Zeus, who, after they have both assumed various animal guises, turns himself into a swan and catches her in the form of a goose. Nemesis then lays an egg which, in many versions of the tale, is brought to Leda (*q.v.*), who hatches Helen from it. There seems also to have been a legend that at some battle, perhaps that of Marathon, Nemesis appeared in person to encourage her worshipers.

The second divine entity of this name is an abstraction—*i.e.*, indignant disapproval of wrongdoing, particularly the disapproval of the gods, with the consequent punishment of a sinful or over-prosperous man; and the eventual personification of that disapproval (first traceable in Hesiod). Pausanias mentions an old cult of "Nemesis" at Smyrna (mod. Izmir), but whether the object of this cult was Nemesis of Rhamnus or Nemesis the abstraction is not clear. That the abstraction was worshiped, at least in later times, is beyond doubt, however; her first altar was said to have been erected in Boeotia by Adrastus, leader of the Seven Against Thebes. In Rome especially her cult was very popular, particularly among soldiers, by whom she was worshiped as patroness of the drill ground (Nemesis *campestris*). In association with Fortune she seems also to have been adored as presiding over races. She had a cult association, the Nemesiaci. (H. J. R.; X.)

NEMESIUS (fl. *c.* A.D. 390), a Christian philosopher, author of a treatise "On Human Nature" (Eng. trans. by W. Telfer, 1955), was, according to the title of his book, bishop of Emesa (in Syria). His book is an attempt to compile a system of anthropology from a Christian standpoint, using as sources various Greek philosophers and men of science. His interest in medicine is marked, the information being in great part derived from Galen, whom, however, he corrects in some details. He first explains the unique position of man as a creature halfway up the scale of beings, who is endowed with a rational soul and shares the nature of the divine and of the perishable; next describes in detail the human frame, the powers of the soul and the emotions; and finally defends in Aristotelian fashion the belief in human responsibility in opposition to fatalism and astrology. (D. J. A.)

NEMI, LAKE, in the Alban hills about 22½ km. (14 mi.) S.E. of Rome, Italy, in the Lazio (Latium) region, is an extinct subsidiary crater in the outer ring of the ancient Alban crater, east of Lake Albano. It is about 3½ mi. in circumference and about 110 ft. deep; the precipitous slopes of its basin are over 300 ft. high and are mainly cultivated. In ancient times it was included in the territory of Aricia and was called Lacus Nemorensis and sometimes the "Mirror of Diana" from a temple and a grove (*nemus*) sacred to that goddess (*see* also DIANA). The worship of Diana there was originally celebrated with human sacrifices; even in imperial times the priest was a man of low condition, a gladiator or fugitive slave, who won his position by slaying his predecessor in fight, having first plucked a mistletoe bough from the sacred grove. The temple itself was one of the richest in Latium; Octavian borrowed money from it in 31 B.C. The remains of its precinct are situated a little above the level of the lake, on the northeast—a large platform, the back of which is

formed by a wall of concrete, with niches, resting against the cliffs. Excavations (now covered in again) led to the discovery of the temple itself, a comparatively small building, 98 by 52 ft., containing objects, none earlier than the 4th century B.C. A road descended to it from the Via Appia from the southwest. The lake is drained by a tunnel about 2 mi. long.

It had long been known that on the west side of Lake Nemi two Roman galleys rested on the lake bottom but attempts to raise them were unsuccessful; they were raided by divers in 1895 and some of the most valuable objects were removed. Finally, in the late 1920s, the water level was lowered and the ships appeared. They were pleasure ships, of the period of the empire, one measuring 210 by 66 ft., the other 233 by 80 ft. Many of the objects found on the ships are in the museums in Rome. The ships themselves were burned by the German army on May 31, 1944.

(G. KH.)

NEMIROVICH-DANCHENKO, VLADIMIR IVANOVICH (1858–1943), Russian novelist, playwright and producer, and a founder of the Moscow Art theatre, was born at Ozurgety, Georgia, on Dec. 23, 1858. In 1890 he took over the drama classes of the Moscow Philharmonic society, and by the end of the 1890s he was already the author of a number of best-selling novels and successful plays. As a writer of the "psychological" school, he laid particular stress on bringing out the psychological undertones in the acting of his pupils, and his first great success in this line was the production at his school of Ibsen's *A Doll's House* in 1896. A year later he had an 18-hour meeting with Konstantin Stanislavski (*q.v.*), at which they laid the foundations of the Moscow Art theatre. It was Nemirovich-Danchenko, too, who was chiefly responsible for introducing Chekhov's plays into the theatre's repertory. In the 1920s he organized the Moscow Art Theatre Musical studio, and he toured the United States in 1925. His work as producer is chiefly remarkable for the adaptation of *The Brothers Karamazov* and *War and Peace* in 1910, and for an operatic version of M. A. Sholokhov's *And Quiet Flows the Don* during the last years of his life. He died in Moscow on April 25, 1943. His autobiography has been translated as *My Life in the Russian Theatre* (1936). (D. MK.)

NEMOPHILA, a genus of North American herbs of the waterleaf family (Hydrophyllaceae), comprising over 15 species found chiefly in the Pacific coast region. They are more or less delicate annuals, with parted, divided or lobed leaves, and small bluish or white flowers, usually blossoming continuously and profusely from early spring to late summer. Several are grown as border plants, especially the baby blue-eyes (*N. menziesi*) and the five-spot (*N. maculata*), which do well in partly shady locations.

Other interesting species are the climbing or purple nemophila or fiesta flower (*N. aurita*), the small white nemophila (*N. heterophylla*) and the small flowered nemophila (*N. parviflora*), the last named ranging from California to Washington.

NEMOURS, DUCS DE. The lordship of Nemours, in Gâtinais (in the modern *département* of Seine-et-Marne), was acquired by the French crown in the 1270s. In 1404 it was granted as a peerage-duchy to Charles III (*q.v.*) of Navarre. After his death in 1425, succession to the duchy was intermittently contested between his daughters' consorts and their heirs till 1462. In that year Louis XI of France confirmed it to JACQUES D'ARMAGNAC, whose father, Bernard, comte de Pardiac (a younger son of the great Bernard VII; *see* ARMAGNAC), had in 1429 married Éléonore de Bourbon-La Marche, daughter of Charles III's daughter Béatrix. The new duc de Nemours subdued Roussillon for France in 1463 but joined the Ligue du Bien Public against Louis XI in 1465. Detached from this by the grant of the governorship of the Île-de-France, he was pardoned for further treason in 1470, but began conspiring again and was taken prisoner at Carlat in 1476. Brought to Paris, he was beheaded on Aug. 4, 1477. The forfeited peerage was restored by acts of 1484 and 1492 to his son JEAN D'ARMAGNAC (d. *c.* 1500), whose brother and successor, LOUIS (d. 1503), viceroy of Naples, was killed in the battle of Cerignola. Their sisters, married into the house of Rohan-Gié, failed to secure the succession.

The title was granted as a peerage-duchy in 1507 to GASTON DE FOIX (1489–1512), who lost his life in his great victory at Ravenna; and as a simple duchy in 1515 to GIULIANO DE' MEDICI (d. 1516; *see* MEDICI). On the death of Giuliano's widow, Philiberta of Savoy (1524), it was assigned to Louise of Savoy, mother of Francis I of France; but in 1528 it was transferred to her half brother PHILIPPE DE SAVOIE, comte de Genevois (1490–1533).

JACQUES DE SAVOIE (1531–1585), Philippe's son by Charlotte d'Orléans-Longueville, became duc de Nemours in 1533. He won a military reputation in the French royal service on the eastern frontier and in Piedmont in the 1550s and against the Huguenots and their German allies in the 1560s. His amorous exploits at the Valois court were also admired: Brantôme characteristically calls him "the paragon of chivalry." After being considered for marriage to Elizabeth I of England in 1559–60, Nemours became interested in Anne d'Este, wife of François de Lorraine, 2nd duc de Guise; and after Guise's death (1563) he repudiated a solemn promise of marriage to Mlle de La Garnache (Françoise de Rohan, who had borne him a son and whose cause was taken up by her Albret and Bourbon relatives) in order to marry Anne in 1566. He later retired to his Savoyard appanage of Genevois and died at Annecy on June 15, 1585.

CHARLES EMMANUEL DE SAVOIE (1567–1595) succeeded his father as duc de Nemours. A supporter of the Holy League, he was appointed governor of Lyonnais just before he was arrested at Blois in King Henry III's coup against the Guises (1588). Escaping to Paris, he quarreled with the duc de Mayenne, withdrew to Lyonnais, took Vienne for the League but was taken prisoner (1593) by the archbishop of Lyon, Pierre d'Épinac. Escaping in 1594, he died in July 1595. His brother and successor, HENRY I DE SAVOIE (1572–1632), who as marquis de Saint-Sorlin had helped the Savoyards to capture Saluzzo (1588) and had fought for the League in Dauphiné, reconciled himself with Henry IV of France in 1596. When the Spaniards went to war against Savoy in 1615, Nemours raised an army to co-operate with them but had to make peace in 1616. Married in 1618 to Anne de Lorraine-Aumale, he died in Paris on July 10, 1632.

Henry's eldest son, LOUIS DE SAVOIE (d. 1641), generally used the title of duc d'Aumale by right of his mother, but was confirmed as duc de Nemours in 1639. His brother and successor, CHARLES AMÉDÉE DE SAVOIE (1624–1652), was married to Élisabeth de Vendôme in 1643 and fought against the Spaniards in Flanders in 1645–46. During the third war of the Fronde (*q.v.*) he took the side of the rebels but caused dissension among them by flirting with the duchesse de Longueville (*q.v.*) and with Mme de Châtillon (Isabelle Angélique de Montmorency) and by quarreling with his brother-in-law, François, duc de Beaufort, who shot him in a duel in Paris on July 30, 1652. He left two daughters: Marie Jeanne Baptiste (1644–1724), married in 1665 to Charles Emmanuel II of Savoy and regent for her son Victor Amadeus II (*q.v.*) from 1675 to 1684; and Marie Françoise Élisabeth (1646–83), whose marriage of 1666 to Afonso VI of Portugal was annulled so that she could marry his brother and supplanter, Pedro II, in 1668.

HENRY II DE SAVOIE (1625–1659), the chess player who had been nominated archbishop of Reims in 1651, succeeded his brother as duc de Nemours in 1652, took a wife in 1657 and died in Paris on Jan. 1, 1659. His widow, Marie d'Orléans-Longueville (1625–1707), was the daughter of Henry, duc de Longueville, by his first wife, Marie de Bourbon-Soissons. This duchesse de Nemours is renowned for her obstinacy in litigation over the Longueville inheritance. Though she finally lost her case as far as the French property was concerned (1698), she established her right to the sovereign principality of Neuchâtel (1699). She died in Paris on June 16, 1707. In her *Mémoires* (first published 1709), which deal with the Fronde, she writes with sympathy toward her father and with particular hatred for her stepmother and other Condés.

Louis XIV in 1672 gave the duchy to his brother Philippe, duc d'Orléans, with whose descendants it remained (*see* BOURBON: Tables III and IV). King Louis Philippe's son Louis Charles Philippe Raphaël d'Orléans, duc de Nemours, is the subject of a separate article.

NEMOURS, LOUIS CHARLES PHILIPPE RAPHAËL D'ORLEANS, Duc de (1814–1896), French prince who after the fall of the July monarchy tried to unite the exiled royalists. He was born in Paris on Oct. 25, 1814, the second son of Louis Philippe (*q.v.*), duc d'Orléans, who became king of the French in 1830. He was made a colonel of cavalry in 1826. In 1831 he was elected king of the Belgians, but Louis Philippe refused that crown in his son's name; even so, Nemours was present at the siege of Antwerp (1832). Later he accompanied three expeditions to Algeria (1836, 1837 and 1841). His conservatism antagonized the liberal opposition in France, and in 1840 the chamber of deputies refused to grant the dowry proposed for his marriage to Princess Victoria of Saxe-Coburg-Gotha. In 1842, however, the death of his eldest brother, Ferdinand, duc d'Orléans, made Nemours the prospective regent of France in the event of Louis Philippe's dying before Ferdinand's son Louis Philippe Albert, comte de Paris, should have come of age. On the outbreak of revolution in 1848 Nemours organized the defense of the Tuileries to cover the king's escape and then tried to accompany the duchesse d'Orléans (Helena of Mecklenburg-Schwerin) to the chamber of deputies to press her son's claims. In exile in England, he sought to effect a reconciliation between the house of Orléans and the comte de Chambord (*q.v.*), as the indispensable preliminary to a restoration of the Bourbon monarchy in France; and he also, in a letter of 1857, urged the comte de Chambord to undertake to maintain the Tricolour flag and the principles of constitutional government. After the Franco-German War and the removal of the legal disabilities of the French princes (1871), Nemours returned to France and was restored to his army rank of divisional general, but the comte de Chambord's insistence on the white Bourbon standard ruined royalist hopes of a restoration. Nemours died at Versailles on June 26, 1896. For his descendants *see* Bourbon: Table IV.

See R. Bazin, *Le Duc de Nemours* (1906). (Je. V.)

NEMOURS, a town of north central France, *département* of Seine-et-Marne, stands on the Loing 15 km. (9 mi.) S. of Fontainebleau and 75 km. (47 mi.) S.E. of Paris by road. Pop. (1962) 6,313. Historic buildings include the Catholic church of St. Jean-Baptiste (13th-16th century), a Protestant meetinghouse and a 12th-century castle housing a museum. The Parc Gréan contains some picturesque rocks. Nemours is on the railway from Paris to Clermont-Ferrand, and on the national route from Paris to Antibes and Italy. The most thriving industry is sand quarrying, a white sand being produced that is 99.92% pure quartz. Nemours is held to derive its name from the fountains dedicated to the Celtic god of springs, Nemausus, and discoveries of Gallo-Roman remains indicate its early origin. The duchy of Nemours was important in the middle ages. The town is the ancestral home of the du Pont family of Delaware, U.S., world-known chemical manufacturers. (L. É. Pe.)

NENAGH (Aonach Urmhumhan), the chief town of northern Tipperary, Republic of Ireland, lies near the river Nenagh, 98 mi. S.W. of Dublin by road. Pop. (1961) 4,317. It is an agricultural centre with some industry, *e.g.*, aluminum ware and chemical products. Of the old castle, Nenagh Round, dating from King John, there exists the circular donjon or keep. There are no remains of the hospital founded in 1200 for Austin canons, and only slight remains of the Franciscan friary, founded in the reign of Henry III. Nenagh was one of the ancient manors of the Butlers, who received for it the grant of a fair from Henry VIII.

NENE (Nen), a river of the east Midlands, Eng., which, from its source on the Jurassic uplands 15 mi. W. of Northampton to its mouth on the southern coast of the Wash, 10 mi. N. of Wisbech, is 90 mi. long. Its upper parts consist of a fan of tributaries draining a broad shallow basin 15 mi. in diameter focusing on Northampton. From there it runs in a broad valley across Jurassic rocks generally northeastward past Wellingborough, Irthlingborough, Thrapston and Oundle to Peterborough, receiving a number of left-bank tributaries, principally the Ise, Harper's brook and Willow brook, and with a gradient gradually decreasing from 20 ft. per mile above Northampton to 3 ft. per mile. At Orton near Peterborough its average discharge is 290 cu.ft. per second, with extremes of 13,500 and 3 cu.ft per second. The last 30 mi. from Peterborough to the Wash via Wisbech is an artificially embanked course across the Fens with a gradient hardly exceeding 8 in. per mile. This is 17 mi. shorter than the old natural course through March. The river has locks as far up as Northampton, which is also reached from the southwest by a branch of the Grand Union canal. Several of its upper tributaries are dammed to form small reservoirs supplying such places as Northampton, Kettering, Higham Ferrers and Rushden. (B. W. S.)

NENETS NATIONAL OKRUG, established in 1929, forms the northern part of Archangel *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., extending as a strip about 150 mi. wide along the northern coast of European Russia, from Mezenskaya Guba (gulf) of the White sea to Baidaratskaya Guba of the Kara sea, together with Kolguyev and Vaigach Islands. Area 64,749 sq.mi.; pop. (1965 est.) 38,000. The surface for the most part is a level marine plain, broken by the northern ends of the Timan hills (Timanski Kryazh) and the Urals (the latter known as Khrebet Pai-Khoi). The whole *okrug* lies within the tundra, with a scanty vegetation of mosses, lichens and dwarf shrubs on poor, waterlogged soil, underlaid by permafrost. In the south are sparse and stunted trees.

The Nenets people, a Finno-Ugrian group formerly known as the Samoyed (*q.v.*), make their living chiefly by reindeer herding, supplemented by a little fur hunting. The formerly nomadic tribes now are settled in permanent villages and only herders move with the animals. Fishing, especially for salmon, is important. The Russian population is concentrated mainly in the one town of Naryan-Mar, on the Pechora river, and the urban district of Amderma. Naryan-Mar, the administrative centre (pop. [1959] 13,200), is an important sawmilling town and processes fish and hides. There are no all-weather land communications within the *okrug*. (R. A. F.)

NENNIUS (fl. *c.* 800), Welsh antiquary who between the years 796 and *c.* 830 compiled or revised the *Historia Britonum*, a miscellaneous collection of historical and topographical information, containing the earliest known reference to Arthur (*q.v.*). He was probably the Nemnius or Nemnivus referred to in an early 8th-century manuscript as the inventor of a Welsh alphabet. In the preface to the *Historia* he describes himself as a disciple of Elvodugus (d. 809), chief bishop in Gwynedd.

The *Historia Britonum* has survived in about 35 manuscripts dating from the early 10th to the 13th centuries. Besides the preface, it contains an account of the six ages of the world, a description of the inhabitants and invaders of Britain, a section on St. Patrick, a list of 12 victories ascribed to Arthur, some Anglian genealogies and accounts of 28 cities and of various "marvels" in Britain. The fullest manuscript (British Museum Manuscript Harleian 3859) also contains two later interpolations, the British annals now known as *Annales Cambriae* and some Welsh genealogies.

The controversy as to whether Nennius himself composed the *Historia* or merely adapted and edited an earlier version is still unresolved. Until Heinrich Zimmer published his *Nennius Vindicatus* (1893), the latter view was universally held, and it remained that of Theodor Mommsen. A. W. Wade-Evans, who ascribed the whole compilation to Nennius, suggested that he attempted to correlate the evidence of his other sources with that of the *De excidio et conquestu Britanniae* of Gildas (*q.v.*). It is Nennius who gives the name Vortigern to Gildas' "proud tyrant" and he is the sole authority for the story of Vortigern's marriage with the daughter of Hengist.

Bibliography.—The *Historia* was ed. by T. Mommsen in *Monumenta Germaniae historica, auctores antiquissimi*, vol. iii (1898), and by F. Lot, *Nennius et l'historia Brittonum* (1934); for Eng. trans. *see* A. W. Wade-Evans, *Nennius's History of the Britons* (1938). *See also* F. Liebermann, "Nennius the Author of the Historia Brittonum," in *Essays in Mediaeval History Presented to T. F. Tout* (1925); Ifor Williams, "Notes on Nennius," *Bulletin of the Board of Celtic Studies*, vol. vii, part 4 (1935); *English Historical Documents*, vol. i, ed. by D. Whitelock (1955).

NEOCLASSICAL ARCHITECTURE: *see* Baroque and Post-Baroque Architecture.

NEOCLASSICAL ART refers to the dominant style of the late 18th and early 19th centuries. Various phases of its course can be distinguished. In France, there are the rococo neoclassicism of the reigns of Louis XV and XVI, the developments of the revolutionary transition including the Directory, consulate and first empire and that of the Bourbon restoration until the July Revolution of 1830. In England, the style is found in the late Georgian phase of the Adam school beginning in the 1760s, in the United States, in the federal style (about 1785–1820), and internationally, in the romantic neoclassicism of the Roman and Greek revivals. Thereafter its waning influence is felt throughout the 19th century in the academic neoclassicism in painting and sculpture, and as a component of the eclectic style in architecture.

The beginnings of neoclassicism are found in the decline of the rococo in France and the Georgian style in England. J. G. Soufflot's Panthéon (1754–1790) in Paris, with its chaste Corinthian portico and Roman detail, reflects the shift in taste, as does Jacques Ange Gabriel's design for the Petit Trianon (1762–66) at Versailles, with its neat geometrical balance of horizontal lines and vertical pilasters surmounted by a classical entablature. Under Louis XVI the Pompeiian influence further curbed rococo decorative extravagances and purified the sense of design. In the work of Robert Adam, who returned to England in 1760 after studying the excavations of Diocletian's palace at Spalato, the Palladian influence gave way to a more authentic neoclassicism. His interiors for private houses show his enthusiasm for the discoveries about Roman domestic architecture at Pompeii. His preferences ran to Roman stucco decoration with such classical motives as scrolls, vases, festoons and candelabra.

In the pictorial arts the reaction to the rococo was evidenced by the unparalleled popularity of Piranesi' prints of ancient Roman ruins and in the paintings of J. M. Vien in France, A. R. Mengs in Germany, and B. West in England. With the great success of J. L. David's "Oath of the Horatii" (1785) neoclassicism was in full swing. David's archaeological enthusiasm led him to model the faces and figures in his pictures after antique busts; and his announced intention was to make the backgrounds and details of his pictures so faithful to the ancient world that if an old Roman should suddenly come to life, he would find himself completely at home.

Neoclassical art reflected an important aspect of the life and thought of the pre- and post-revolutionary generation, especially in France and British-colonial America; and the brave new revolutionary world figuratively dressed itself in the ancient toga.

At this time of swift and violent social and political change, the rising middle class began to assume a more active leadership in public and private affairs, and the straightforward simplicity and uncomplicated forms of neoclassicism made a strong appeal to the stoic and austere taste of the revolutionists. After the chaos and confusion of these years, American and French citizens felt the need for the disciplined orderliness, economy of means and logical predictability inherent in neoclassical forms. As monarchical rule was overthrown in the United States and France, the citizenry discovered an emotional identification with the forms and images of the ancient republics. To them Greece and Rome were not dead civilizations, but the living birthplaces of freedom and democracy. Their affinity with the ancient world not only gave them a sense of heroism and glory, but it also furnished convenient precedents for the new governments in America and France, and to a certain extent the British constitutional monarchy. The ancient Athenian commonwealth and Roman republic became the symbols of liberty and the new order. The senior legislative houses in the United States, France and later in the Latin American republics, were named senates after the old Roman prototype.

George Washington was acclaimed as the father of his country, in emulation of the ancient Roman honorific *pater patriae*. The new U.S. capital was destined to be built on classical, rather than baroque, colonial or Georgian, models; and the new legislature was to be housed on Capitol hill, a site named after one of the seven hills of Rome.

This was a generation that built new government buildings, municipal offices, public libraries, art museums, national repertory theatres, concert halls, hospitals, hotels, banks and railroad stations. The Roman revival was perhaps strongest in Paris, which Napoleon envisaged as a new Rome replete with temples of glory, triumphal arches, and monumental commemorative columns. In the United States the federal style also followed Roman models; Thomas Jefferson designed the Virginia state capitol after the Maison Carrée at Nîmes, and his residence at Monticello and the Rotunda of the University of Virginia after the Roman Pantheon. The Greek revival generally found a foothold in the countries least sympathetic to Napoleon's new Roman empire. More chaste and correct than its Roman counterpart, the style is seen in the following: the Brandenburg gate at Berlin (1788–91), modeled after an archaeological reconstruction of the Athenian Propylaea; the semicircular Corinthian colonnade of the Hall of Representatives (1803–17) at Washington, D.C., inspired by the Monument of Lysicrates in Athens; St. Pancras' church (1818–22) and the Ionic façade of the British museum (1823–47) in London, after the Erechtheum; and the Valhalla (1830–42) at Regensburg, Bavaria, after the Parthenon.

In spite of their deeper penetration into the classical spirit, the neoclassicists still suffered from a lack of detailed knowledge about antiquity. Winckelmann's ideal statues were the Apollo Belvedere and the Laocoön, both late Hellenistic examples rather than those of the earlier and superior Hellenic style. Sculptors left the irises and pupils of eyes uncarved because they did not know that the ancients painted in such details. A. Canova and B. Thorvaldsen both turned the human body into the cold marble of antique statuary instead of molding marble into a semblance of living flesh, as the great Greek sculptors had done. Josiah Wedgwood imitated the Greek vases of the fifth century B.C., which he mistakenly took to be Etruscan.

After David and his successor J. A. D. Ingres, French neoclassical painting degenerated into the sterile academicism of the later 19th century as exemplified by Thomas Couture's once-popular "Romans of the Decadence" (1847), Adolphe Bouguereau's "Birth of Venus," and the stereotyped pictures of Puvis de Chavannes, Alexandre Cabanel and Marcus Collin. Neoclassical architecture nevertheless continued in various modified forms until it was supplanted by the new materials, building methods and aesthetic viewpoints of the machine age.

The popularity of neoclassicism can be traced to several sources. A series of publications stimulated a shift in taste toward a new and more authentic interpretation of antiquity. Among the early histories was Montesquieu's *Considerations on the Causes of the Greatness of the Romans and of their Decadence* (1734), an important precursor of Gibbon's monumental *Decline and Fall of the Roman Empire* (1776–1788), which reached a wide public and focused attention on ancient Rome. Winckelmann's *Thoughts on the Imitation of Greek Works in Painting and Sculpture* (1755) and his epoch-making *History of Ancient Art* (1764) made a clear distinction between Roman and Greek styles and brought forth cogent arguments to prove that Greek art was superior to Roman. Besides being the founder of modern systematic classical archaeology and the one who divided Greek art into logical periods, Winckelmann formulated the neoclassical aesthetic with its professed ideals of pure beauty, noble simplicity, and quiet grandeur. Winckelmann's ideas and conclusions were further expanded and applied to drama and the other arts by G. E. Lessing in his brilliant critical study, *Laocoön*.

Some important archaeological discoveries were made. After the discovery of Herculaneum in 1719 and Pompeii in 1748, the subsequent excavations attracted wide attention. Other expeditions followed; R. Wood published his findings about the Roman ruins at Palmyra and Baalbek (1737–57), and in 1769 his *Essay on the Original Genius and Writings of Homer, with a Comparative View of the Ancient and Present State of the Troade*. J. Stuart and N. Revett visited Athens and published their drawings and comments on the acropolis buildings in *Antiquities of Athens Measured and Delineated* (1762). The London Society of Dilletanti continued their archaeological work and later expeditions were published in *Ionian Antiquities* (1769) and *Unedited Antiquities of Attica* (1817).

C. L. Clérisseau in turn brought out his study of the Roman remains at Nîmes, and thereafter the archaeological work gained momentum with such major events as Lord Elgin's shipment of the Parthenon sculptures to London, H. Schliemann's excavation of Troy and Mycenae in the 1870's, and the discovery of the Mausoleum at Halicarnassus and the great Altar of Zeus at Pergamum (Bergama). All these books were concerned not only with the existing ruins but also with restorations of the ancient structures based on detailed measurements and as much knowledge as they could muster. Thereafter throughout the 19th century, all the scattered information and isolated discoveries were collated by scholars, documented and made available.

The romantic movement became increasingly popular. The idealization of the Greco-Roman world was as much a form of romantic escapism as that of the middle ages. The noble Greek and virtuous Roman embodied the romantic longing for a past golden age quite as much as the image of the pious medieval knight in armour. Later, when the romantic spirit became identified with the various struggles for national independence, the cause of Greek liberation from the tyranny of the "terrible Turks" symbolized the struggle of classical ideals against the ugliness of the contemporary world.

The emotional espousal of Greek independence that was prevalent all over Europe and the U.S. was actively expressed in letters and the arts. Both classical countries—Greece and Italy—were under the yoke of foreign tyrants, and intellectuals and poets passionately championed their cause. Byron's *Isles of Greece*, Shelley's *Hellas* and *Prometheus Unbound*, Friedrich Hölderlin's *Hyperion*, Victor Hugo's *Les Orientales*, and Vittorio Alfieri's tragedies, all upheld these liberation movements. Beethoven's ballets, *Ruins of Athens* and *Prometheus*, and Delacroix' painting, *Massacre at Chios* were based on incidents describing the oppression of the Greek people. Finally the whole movement was dramatized by Byron's quixotic death in one of the Greek skirmishes against the Turks.

Education, based on the study of classical languages and literatures, spread to an ever-widening circle. From the Renaissance through the 19th century, education was constantly closing the gulf between scholars and the public as a vast new reading public was brought into being. The heart of education was the study of the classics, which were considered indispensable for a gentleman. So also was the grand tour to Italy to view the ruins of antiquity. A classical orientation in the arts followed quite naturally, and a common set of symbols drawn from ancient literature, mythology and art brought about an intellectual unity that transcended the barriers of language, creeds and national frontiers and brought all the nations of western civilization together in the last completely international style—neoclassicism.

(Wm. F.)

NEODYMIUM, the second most abundant element of the rare-earth group, is a silver-white metal. The symbol for neodymium is Nd, the atomic number is 60 and the atomic weight is 144.24. It is slowly oxidized by air, burns easily to give the sesquioxide (Nd_2O_3) and reacts gradually with cold water, or rapidly with hot water, to liberate hydrogen. The metal is used in the electronics industry, in the manufacture of steel and as a component of a number of alloys, among them the misch metal (*see* Cerium) used for lighter flints. Its compounds are used in the ceramics industry for glazes and to colour glass. The crude oxide is employed for counteracting the colour of iron in glass and the more pure compound is used in the production of the only known glass that is bright purple in colour. A mixture of neodymium and praseodymium absorbs light in the region of the harmful sodium D lines and therefore is used in the glass of welders' and glass blowers' goggles. The oxide and chloride are effective catalysts in certain organic reactions.

Neodymium was discovered by C. A. von Welsbach in 1885 when he separated salts of didymium, a metal he thought was a simple element, into two chemically distinct fractions, neodymium (*neo*, "new") and praseodymium. Neodymium occurs along with other rare earths in many minerals but is produced commercially almost exclusively from monazite; it is also found in the products of atomic fission. The naturally occurring element consists of isotopes with mass numbers 142, 143, 144, 145, 146, 148 and a long-lived radioactive isotope, 150.

Until World War II the element was separated by fractional crystallization procedures; however, an ion-exchange technique is now used for commercial production. The metal is prepared by electrolysis of the fused halides or by thermoreduction of its salts by alkali or alkaline earth metals. The melting point of the metal is 1,024° C.; its density is 7.004 g. per cubic centimetre for the hexagonal close-packed structure; other forms are known to exist.

Neodymium behaves as a typical rare earth and forms a series of blue-coloured salts in which it is trivalent. The ionic radius is 0.995 Å. The reddish-violet solutions have a series of sharp absorption lines in the visible and ultraviolet region of the spectrum that may be used for quantitative analysis. Because of unpaired electrons, the trivalent neodymium ion is paramagnetic. The thermal neutron absorption cross section is 52 barns. *See* Rare Earths. (Ld. B. A.)

NEOGRAMMARIAN is the name of a school of linguistics flourishing in, and spreading from Germany (*Junggrammatiker*) after 1875. The founders and leaders, August Leskien, Hermann Osthoff, Karl Brugmann and Berthold Delbrück, had numerous disciples in all countries. They proposed that the living languages (as opposed to the dead languages, *i.e.*, those not spoken any longer by native speakers) should be given stronger emphasis than hitherto accorded them by philologists, and that greater attention should be paid to the psychological forces in language. And they stated that every historic sound change occurs according to rules, so-called sound laws, which "suffer no exceptions." This means that every occurrence of the phoneme /x/, at a certain moment in the history of a language, under certain phonetic conditions, is represented by the phoneme /y/ in a later stage and that every apparent deviation from this law is to be explained, not as fortuitous "exception," but as a consequence of some overriding interference. Viewed thus, the often voiced objection against the "exceptionlessness" of the sound laws appears groundless. One of the chief causes cited by Neogrammarians as capable of neutralizing a sound law is analogy, which they considered a psychological force causing speakers to adhere to patterns, especially paradigmatic, whereby the expected regular development seems canceled. For example, Latin *amo* "I love" regularly becomes French *(j')aime;* but although the infinitive *amare,* with the stress not on the first but the second *a,* should regularly give *amer*, the word is in fact *aimer*, with the *ai-* extended by analogy to all forms of this verb regardless of the place of the stress. Apart from analogy, the programmatic statement concerning the importance of psychology scarcely bears fruit in neogrammarian practice. Also the theoretically required emphasis on living languages has little practical consequence in the Neogrammarian works (except insofar as some were also dialectologists): they deal mainly, and masterfully, with dead languages and the reconstruction of unattested proto-languages.

Despite often bitter attacks on neogrammarian theory (justifiably addressed to some incomprehending malpractitioners), all historical linguists implicitly accept and operate with the principle of regular change.

Hockett, *A Course in Modern Linguistics* (1958); Holger Pedersen, *Linguistic Science in the Nineteenth Century* (1931). *See* also the works of the authors named in this article. (E. Pm.)

NEO-HEGELIANISM, a term applied, generally by unsympathetic critics, to the doctrines of the idealist school of philosophers which was prominent in Great Britain and in the United States between 1870 and 1920; its use is sometimes extended to cover other philosophies of the period which were Hegelian in inspiration, for instance those of Benedetto Croce and of Giovanni Gentile (*qq.v.*). Neo-Hegelianism in Great Britain developed originally as a natural sequel to the semipopular work of S. T. Coleridge and Thomas Carlyle. Its exponents sought to give

philosophical expression to a widely felt antipathy to the prevailing materialism and utilitarianism and turned to the writings of the German school as containing penetrating, if oracular, statements of an alternative view.

The ideas of Kant, Fichte, Schelling and Hegel were at first all used for this purpose, but closer knowledge led to a more reserved attitude to Kant and to an increasing tendency to look to Hegel for the elements of a really sound philosophy. There was, however, always a certain reluctance among the best-known members of the school to let themselves be described as "Hegelians": T. H. Green and F. H. Bradley both issued disclaimers on this point and both in fact were influenced by British ways of thinking which they shared with the opponents whom they criticized. It remains true, nevertheless, that the outlook of each was determined by Hegel more than by any other writer and that their work can be regarded as an attempt to tackle the philosophical problems of their time from a standpoint which was broadly Hegelian.

What Green described as "the vital truth which Hegel had to teach" was put by him in 1880 in the following terms: "That there is one spiritual self-conscious being, of which all that is real is the activity or expression; that we are related to this spiritual being, not merely as parts of the world which is its expression, but as partakers in some inchoate measure of the self-consciousness through which it at once constitutes and distinguishes itself from the world; that this participation is the source of morality and religion" (reprinted in *Works*, vol. iii, p. 146 [1888]). These words might well be taken as expressing Green's own personal philosophical creed and as indicating the central tenets of the Neo-Hegelian school as a whole. The Neo-Hegelians were opposed to materialism and to naturalism in metaphysics; to analyses of consciousness in terms of sensation and of the association of ideas in theory of knowledge; to psychologism (*q.v.*) and to formalism in logic; and to the "greatest happiness" principle as well as to the doctrine of duty for duty's sake in ethics. In politics they dissociated themselves from the prevailing individualism and tended to look on the state as a living community rather than a mutual benefit society. Their attitude to religion was ambiguous, for though they were in general sympathetic to religious claims, they made no secret of the fact that they could not accept them at their face value. Much of the popular attraction of their philosophy, indeed, sprang from its seeming to provide a rational alternative to the religious beliefs which, with the spread of scientific knowledge and the shock of Darwin, men found it increasingly difficult to hold; and one reason for its decline may have been that, as religious difficulties ceased to be a central preoccupation, less need was felt of such a substitute for religion as this philosophy offered.

The earliest representative of this way of thinking in Great Britain was J. F. Ferrier (1808–64), a professor at St. Andrews, who was, however, influenced as much by George Berkeley as by German writers. Ferrier's *Institutes of Metaphysics* appeared in 1854, but it was not until somewhat later that the ideas it expressed gained general currency. The creation of an idealist "school" was due to two men in particular: T. H. Green (1836–82), who taught at Oxford from 1860 onward, and Edward Caird (1835–1908), professor of moral philosophy in Glasgow from 1866 to 1893. Green was notable for his moral earnestness, personal integrity and intense interest in contemporary life, Caird for the breadth and thoroughness of his scholarship; and both were highly effective teachers. Neither had the philosophical insight and originality of their younger contemporary, F. H. Bradley (1846–1924), in whose works Neo-Hegelianism reached its intellectual high-water mark. The skeptical cast of Bradley's mind was, however, uncongenial to many who shared his general outlook; much misgiving was caused by the ruthless dialectic and apparently negative conclusion (which Caird described as "a manifest self-contradiction") of his *Appearance and Reality* (1893).

The fierce logical criticism to which Neo-Hegelian doctrines were subjected, notably by G. E. Moore and Bertrand Russell, in the opening years of the 20th century, may be said paradoxically to spring directly from Bradley's own work, with its insistence on subjecting all ideas, however seemingly sacrosanct, to remorseless scrutiny. Though Bradley himself and his polished but less gifted colleague Bernard Bosanquet (1848–1923) did their best to meet the attack, their efforts in the end were of no avail.

Neo-Hegelianism in the United States sprang from the work of the Boston Transcendentalists, whose knowledge of German philosophy was, however, mostly secondhand; it owed much of its advance to the efforts of W. T. Harris (1835–1909) and to the *Journal of Speculative Philosophy* which he founded in 1867. Its most distinguished and determined proponent was Josiah Royce (1855–1916), professor at Harvard from 1882, though Royce's idealism, with the special place that it assigned to the will, was closer to the ideas of Fichte than to those of Hegel himself. Royce's distinguished contemporaries C. S. Peirce and William James both repudiated his metaphysics; yet Peirce had described himself as an "idealist" in his early life, and even James had experienced the Hegelian influence to some extent. The same was true of James's successor John Dewey, who began life as a Hegelian and, despite his antipathy to absolutes, retained certain Hegelian features in his thought, notably a tendency to denounce abstractions and a reserved attitude toward the claims of formal logicians. *See* also the individual articles on the several philosophers mentioned.

NEO-KANTIANISM is a term used in a rather arbitrary way to cover a wide variety of philosophical movements that not only show the influence of Kant's thought but also explicitly claim to go back to Kant, to free his system from inconsistencies and other errors, or to develop it further in the light of new mathematical and scientific discoveries (*see* KANT, IMMANUEL). All these movements agree to some extent with the Kantian intention of a synthesis of empiricism and rationalism and hold that theoretical and practical thought involves empirical and nonempirical concepts. They all claim to use the Kantian so-called critical method of philosophy. They differ from each other chiefly in the emphasis that they lay on different parts of Kant's work. Neo-Kantianism as a deliberate revival of Kant's thought starts about the middle of the 19th century. It has become usual to distinguish schools of Neo-Kantianism, as follows:

The Physiological School.—Represented mainly by Hermann von Helmholtz (1821–94; *Handbuch der physiologischen Optik*, 1856) and Friedrich Albert Lange (1828–75; *Geschichte des Materialismus*, 1866), the physiological school interprets the creative and modifying functions of the mind in terms of the organization of external stimuli by the nervous system. These give rise to signs (not pictures) of external objects, and their coherence is physiologically explained. The post-Kantian physiology is regarded as confirming the main Kantian doctrines. But the philosophy of space, time and mathematics must be modified in accordance with the discovery of non-Euclidean geometry. The "synthetic a priori principles," in other words the presuppositions of all science, have their basis in the structure of the human brain and nervous system and are not capable of being justified as necessary a priori.

The Realist School.—The chief exponent of realist Neo-Kantianism is Alois Riehl (1844–1924; *Der philosophische Kritizismus und seine Bedeutung für die positive Wissenschaft*, 1876–87), who not only emphasizes the Kantian rejection of speculative metaphysics but also denies the possibility of any scientific or absolute, as opposed to a merely persuasive ethics. To speak generally, the school can be regarded as a compromise between Kant's philosophy and positivism. Its main contributions are in the field of the philosophy of the natural sciences.

The Marburg School.—Founded by Hermann Cohen (1842–1918; *Logik der reinen Erkenntnis*, 1902), this school is also mainly concerned with philosophy of science, in particular with an inquiry into its necessary presuppositions after the fashion of the Kantian "Transcendental Logic." It differs from Kant in regard-

ing sense-perception as ultimately analyzable into relations between concepts. Cohen assigns an overwhelming importance to the "infinitesimal" calculus for the understanding not only of physics but of all science. Some of his speculations about the infinitely small and the nature of mathematics are incompatible with later developments in the foundations of mathematics. Another prominent member of the Marburg school was Paul Natorp (1854–1924; *Die logischen Grundlagen der exakten Wissenschaft*, 1910).

The Baden School.—Most deeply influenced by Kant's *Critique of Practical Reason,* this school interprets every kind of judgment as normative. Its main representative, Wilhelm Windelband (1848–1915; *Einleitung in die Philosophie*, 1914), is also important as a historian of philosophy. His classification of the sciences into nomothetic sciences, which discover general laws, and ideographic sciences, such as history, which describe particular events, has been accepted by many historians and sociologists. Even the ideographic sciences presuppose normative propositions, namely those that distinguish what in a description is to count as an important feature. Philosophy itself is conceived as the general critique of thought, which in turn is always normative. Heinrich Rickert (1863–1936; *Die Grenzen der naturwissenschaftlichen Begriffsbildung*, 1896–1902) also belongs to the Baden school.

The Relativistic School.—This school derives its general point of view from the "Transcendental Dialectic," in particular from Kant's doctrine that it is sometimes useful to treat the empirically empty ideas of reason as if they were true of experience. Its theory of knowledge is pragmatist, truth being conceived as utility for survival. Its ethics is positivistic. Normative ethics proposes ideals, descriptive ethics describes socially accepted moral standards; neither admits of an a priori justification, as attempted by Kant. Representative of this school is Georg Simmel (1858–1918; *Hauptprobleme der Philosophie*, 1910).

The School of Fries and Nelson.—This school considers the "Transcendental Aesthetic" as the model of philosophical method. Both Jakob Friedrich Fries (1773–1843; *Neue Kritik der reinen Vernunft*, 1807) and Leonard Nelson (1882–1927; *Über das sogennante Erkenntnisproblem*, 1904, and *Vorlesungen über die Grundlagen der Ethik*, vol. i, 1917) distinguish sharply between the system of synthetic a priori principles and their justification, a distinction which reminds one, as Nelson emphasizes, of the distinction which formalist mathematicians make between mathematics and metamathematics (*see* MATHEMATICS, FOUNDATIONS OF). The justification of the principles of mathematics consists in showing that they merely reiterate in propositional form an immediate, intuitive (nonpropositional) knowledge of the structure of space and time. The justification of nonmathematical synthetic a priori principles consists in establishing that they too reiterate immediate, though nonintuitive and originally obscure, knowledge. This procedure of justification is psychological and results in empirical propositions *about* the a priori principles, namely empirical propositions to the effect that the principles correspond to nonpropositional immediate knowledge.

According to Nelson the so-called theory of knowledge, because it tries to justify propositions by deriving them from other propositions and not by establishing their relation to immediate knowledge, is involved in a vicious circle, a defect from which Kant's philosophy of natural science and morals also suffers. Nelson's philosophy of mathematics agrees with Kant's in holding that Euclidean geometry, and no other, describes the structure of perceptual space. In the light of their methodology, the school of Fries and Nelson made contributions to almost all branches of philosophy. (S. Ko.)

NEOLINGUIST: *see* NEOGRAMMARIAN.

NEOLITHIC. In 1865 Sir John Lubbock, in describing cultural evolution, termed Neolithic all those remains of prehistoric man that included stone tools shaped by polishing and that appeared in the archaeological record before the emergence of metal, or the Bronze Age. He thus distinguished the Neolithic from the Paleolithic (*q.v.*) or age of chipped stone that preceded. Since Lubbock's definition, the term Neolithic has taken on many additional meanings and there is no consensus in the use of the word. Three criteria are most often included in definitions. Neolithic archaeological assemblages are those having (1) polished stone tools; (2) pottery; and (3) horticulture and/or domestication of animals.

These criteria and combinations of them are used in specific ways by specialists who work in certain restricted areas. Thus in Europe, Neolithic usually means that the prehistoric people had polished stone hoes and axes and had an economy based on agriculture supplemented by hunting and sometimes fishing. Some groups had permanent villages whereas others regularly moved to new farm land. Extensive trade in luxury items such as amber and sea shells was prevalent. By contrast, workers in western U.S.S.R. call assemblages Neolithic when they contain no metal but do have pottery. The people lived by hunting and fishing very much as people had done in the Paleolithic. Again, by contrast, in the Americas the term Neolithic is rarely used when referring to the indigenous cultures even though they may satisfy all three criteria.

One can assign no specific time to all archaeological assemblages that might be called Neolithic. To use one criterion, for example, agriculture had begun bv 7000 B.C. in the near east while Europe stayed Mesolithic (*q.v.*), and agriculture did not reach Europe in force until 3000 B.C. In the near east by 3000 B.C. urban civilizations had begun and these archaeological assemblages are no longer referred to as Neolithic. In many parts of the world agriculture replaced a hunting economy only in the last few centuries.

Without careful definition the use of the term Neolithic is misleading. Since Lubbock's time archaeologists have discovered that man's prehistory is too complicated to be described by single terms describing unilinear evolution.

(F. A. HE.)

NEON, a gaseous element found in the atmosphere and represented by the symbol Ne. It belongs to the family of noble gases, composed of helium, neon, argon, krypton, xenon, and radon, which comprise the zero group of the periodic system.

Neon is used in a variety of lamps and other electrical devices which take advantage of its unusually high electrical conductivity and light-emissive power. The brilliant orange-red light emitted from "neon tubes" in which an electrical discharge passes through the gas under a pressure of a few millimetres of mercury first became a familiar sight in the 1920s. Most gaseous conduction lamps and fluorescent lamps contain neon as a component of the gaseous mixture which carries the electricity. Other neon-tube devices include lightning arresters, high-voltage testers and negative glow lamps. The latter can be built with electrodes in the form of figures or letters suitable for display purposes.

Neon has the atomic number of 10 and an atomic weight of 20.183. Its stable isotopes, listed in order of decreasing abundance, have mass numbers of 20, 22 and 21. Short-lived radioactive isotopes of mass numbers 18, 19, 23 and 24 have been reported. Electrons of the atom occupy and fill the K and L ($2s^2$ $2p^6$) shells.

The element was discovered in 1898 by Sir William Ramsay and M. W. Travers as a component of the most volatile fraction of liquefied crude argon obtained from air and was given a name meaning "the new one."

Neon is widely distributed in nature and occurs in traces not only in the atmosphere but also in gases trapped within the earth. The content in dry air is close to 0.0018% by volume. Industrial production of the element is accomplished by fractional distillation of air. The most volatile fraction is composed of helium neon and nitrogen. The latter gas is removed by chemical absorption and the neon is then separated from helium by selective adsorption on activated charcoal at low temperature.

The following physical constants have been selected from technical literature, most of the values being taken from a table critically compiled by F. P. Gross: density of the gas at 1 atm. pressure and 0° C., 0.8999 g. per litre; density of the liquid at its boiling point, 1.204 g. per millilitre; normal boiling point, −246.09° C.; freezing point, −248.61° C.; critical temperature, −228.75° C.; critical pressure, 26.86 atm.; heat of vaporization at the normal boiling point, 20.8 cal. per gram; heat of fusion, per gram, 3.9

cal.; ionization potential for first electron, 21.5 v.; solubility in water (neon at 1 atm. pressure) at 25° C., 0.0101 ml. (measured at 1 atm. pressure and 0° C.) per millilitre of water; at 15° C., 0.0108 ml. of neon per millilitre of water. Since the ratio of the specific heat of the gas at constant pressure to that at constant volume is 1.642, it may be concluded that a single atom of the element comprises a molecule.

Neon appears to form no stable chemical compounds and apparently attracts other atoms only by the relatively weak interatomic action known as van der Waals forces. Procedures for the analytical determination of neon provide for measuring the gas after it has been isolated by chemical absorption of reactive gases on hot calcium or other reagent and separation of helium, argon, krypton and xenon by physical means. Such a physical separation is usually accomplished by fractional desorption from cold activated charcoal or by diffusion (of helium) through hot quartz. The element is recognized by its characteristic spectrum which contains many beautiful red lines.

NEO-ORTHODOXY is the American name for a theological movement known in Europe as CRISIS THEOLOGY and as DIALECTICAL THEOLOGY. Of these three names, perhaps Crisis Theology is the most appropriate, because the movement began as and remains a Protestant response to the crisis of Christendom after World War I. Two world wars in the 20th century, the rise of totalitarian regimes, the decline of Christian humanism in western culture, together with a premonition of disasters yet to come, led to the view that Christendom is under divine judgment and at the parting of ways; that is, in a state of crisis. The phrase Dialectical Theology refers to the preference of the theologians under consideration for stating their insights in terms of paradox; for instance, that the Bible is the Word of God to man and man's words about God, or that man is at once creature and sinner, good as creature and evil as sinner. Apparently contradictory statements are made in the interests of "truth" so as to suggest both the mystery of human life and the limits of human thought. According to this theology, this is the only proper way to speak about God and man. The meaning of Neo-orthodoxy will appear in the rest of this article.

The origins of Neo-orthodoxy, as of existentialism in philosophy, are usually traced to Sören Kierkegaard (1813–55), who saw the western culture of his day, including its religious institutions, as destructive of humanity. He wrote against objectivity as lacking in seriousness and declared, especially against Hegel and orthodoxy, that "truth is subjectivity." Friedrich Nietzsche, who attacked Christendom as having lost its soul and cried out "God is dead," and Fëdor Dostoevski, who in his novels celebrated the freedom of man as well as uncovering his bondage, both came to make a prophetic impression upon European thought. The anti-idealistic and antiscientific writings of existentialist writers such as Karl Jaspers and Martin Heidegger must also be kept in mind. Further, the Marxist criticism of capitalism exerted considerable influence upon Neo-orthodoxy, and so did depth psychology. In short, Neo-orthodoxy was occasioned by the spiritual shock experienced by the European mind under the impact of the 20th-century age of anxiety and commotion.

Neo-orthodoxy first responded to the age with a negative judgment upon it. In *The Theology of Crisis*, a series of lectures given in the U.S. in 1928, Emil Brunner repudiated modern European culture by attacking idealism, scientism, rationalism, evolutionism, romanticism, immanentism and liberalism. What he saw in all this was man's pride and self-deification which he regarded as at the root of all evil in the modern world. Man had repudiated his finitude and responsibility before the God of the Bible. He had thus put himself in a fundamentally false position, and lived and acted on the basis of a lie which could not but be, as it was, his undoing.

In the same year a series of essays by Karl Barth appeared in English under the title *The Word of God and the Word of Man*. These essays, written between 1916 and 1923, are built upon the contrasts between the righteousness of God and the righteousness of man, the Bible and western culture, the preaching of the gospel and the preaching of religion. At every turn the discontinuity between God and man is set forth and it is made clear that unless Christendom once again listens to the biblical word of God addressed to it from beyond its religion, philosophy and ethics, it is lost.

The same theme was worked out by Barth in *The Epistle to the Romans* (1918, 1921 *et seq.*, trans. from the 6th ed. by Edwyn C. Hoskyns, 1933), which made a profound impression upon Protestant thought in Europe. Here Barth took up Kierkegaard's theme of "the infinite qualitative difference" between God and man, and declared that there is no way from man to God. He wrote of God's self-revelation in judgment and mercy, and called the church to repentance. However, this early writing of Barth was inspired in the main by a vision of the collapse of European culture.

The Epistle to the Romans led Christian thinkers, above all Barth himself, to re-examine the Bible and the faith of the Christian church. Men's eyes were opened to the "strange new world within the Bible" and to the hardly less strange theologies of the Protestant Reformation with their doctrines of justification by faith alone and God's sovereignty over his creation. They began to speak and write seriously of God who is not man and of the word of God to man, of Jesus Christ the Lord, of revelation and faith. The outcome of the process was the rediscovery of theology itself as an intellectual activity growing out of the church's concern with its faith and obedience in Jesus Christ.

In 1932 Reinhold Niebuhr published his *Moral Man and Immoral Society*. This book marks the beginning of Neo-orthodoxy in the United States. It administered a telling blow at a Christianity whose "gospel of love" had made it inept in dealing with the realities of political life in which coercion is a constant and operative factor. Niebuhr struck at idealism, rationalism, optimism and the like, and argued that the amoral and immoral character of nations and classes requires justice through the use of force as well as through religion and enlightenment. He began to speak forcefully about sin and repentance, and insisted that Christianity is above all a critical principle which brings western culture under the judgment of God. Gradually Niebuhr turned to the Bible and to Augustinian theology for insight into "human nature and destiny," and elaborated his views in a number of books as well as innumerable articles which constitute the chief body of Neo-orthodox writing in America. Niebuhr's competence as a political observer gave unusual authority to his theology which he elaborated in constant debate with secular culture.

Other important Neo-orthodox theologians include Friedrich Gogarten, who collaborated with Karl Barth in the early years of the movement; Rudolf Bultmann, who combined Crisis Theology with the existentialism of Heidegger; H. Richard Niebuhr, who made important contributions to the study of Christianity and culture; Nikolai Berdyaev, who was at once a radical critic of western culture and the author of numerous works in which he elaborated a personalism of his own as against "objectivity" in western philosophy; and Paul Tillich, who criticized the dominance of "technical reason" in modern society and elaborated a "philosophical theology" in which "depth of reason" and faith entered into a much debated alliance.

These theologians are called Neo-orthodox because they speak the traditional language of the Christian church as found in the Bible, the creeds and the main line of orthodox theology. They have written of the Trinity, the Creator, the fall of man and original sin, Jesus Christ the Lord and Saviour, justification, reconciliation and the Kingdom of God. The language is the language of orthodoxy but, as the orthodox were quick to see, the meaning of the language has undergone radical changes. The new theologians repudiated the literalism of later orthodoxy. According to them the world was not created in six days. There was no man by the name of Adam who listened to a wife who listened to a serpent and thus sinned and plunged mankind into ruin. Jesus

was not born of a virgin and he did not walk on water. The Bible itself was not written under the dictation of the Holy Spirit and it contains much that is not literally true. In short, the new theologians, assuming modern man's aversion to "physical miracles," refuse to go back to supernaturalism. In this they are modernists. The miracle of the Christian faith to them is Jesus Christ and his gospel proclaimed in the church for the salvation of the world.

To Neo-orthodoxy the controversy between science and religion, which occupied a prominent place in the 18th and 19th centuries, resulted from failure, on the part of both defenders and opponents of Christianity, to understand the nature of the Christian faith. It presents this nature as having to do with faithfulness to God and man in this world and not with opinion about the world in itself as envisioned by scientists.

Neo-orthodoxy in the main is concerned with the problems raised by modern culture and not by the modern sciences. On the other hand, scientism as an aspect of culture itself is subjected to radical criticism. Neo-orthodoxy does not deny the evolution of the species but it rejects evolutionism as an optimistic view of history having a dubious logical basis in biology. It does not repudiate the scientist's self-forgetfulness as a person when occupied with observation and experiment, but it rejects objectivity in human relations. It does not deny logic as integral to scientific explanation, but it rejects the kind of determinism that makes freedom in any sense illusory. Scientism is understood by the Neo-orthodox as incompatible with their fundamental thesis that man is a responsible being and that unless he is understood as such, he is not properly understood as a human being. Neo-orthodox polemics against science, reason, autonomy, with repeated charges of pride and self-idolatry against modern man, are directly or indirectly related to the conviction that modern culture, as largely dominated by science and "technical reason," has become blind to humanity itself as response to persons. In this way, as in others, Neo-orthodoxy is itself related to existentialism. It is also related to liberalism in its aversion to orthodox literalism and authoritarianism and in its humanistic concern for the dignity of persons in the machine age.

Neo-orthodox theology may well be regarded as a set of variations on the theme of man's existence as a responsible being.

1. God as the sovereign Other is the Person who places man under an inviolable responsibility. God transcends man as Creator and Redeemer, and therefore as the Source of responsibility which is neither in man nor in his world. God speaks his Word to man, and in this peculiarly personal act he lays his claim upon man and obligates him to respond to him and thus to exist as a human being. He addresses man in his freedom and love as God, through the freedom and love of Jesus the man which constitute his humanity and illumine our own existence as fellow men.

2. Neo-orthodox preoccupation with Jesus Christ as the Son of God in whom the Father reveals himself to man is understood most readily in the light of Christian humanism. It includes a polemic against natural theology, which argued from nature to God, and in doing this not only obscured God who speaks but also man who is contradistinguished from nature in that he exists in his response to God and to his fellow men. In singling out Jesus Christ as the self-revelation of God, Neo-orthodoxy also singled out man and his responsiveness and recognized a unique dignity in him.

This in part explains also the emphasis upon the humanity of Jesus which is characteristic of Neo-orthodoxy. In the responsibility of the man Jesus, man comes into his own as a person and a fellow man. Thus Jesus acts as the Word of God to man and as man who exists in hearing God's Word.

3. Jesus Christ is, according to this theology, the Word become flesh for our salvation. Therefore, it places a new and searching emphasis upon man the sinner. God reveals himself in the freedom and love of Jesus, and in his forgiveness. But forgiveness reveals man's sin. Therefore, man knows God and himself as a sinner; without such knowledge he knows neither God nor himself. Man knows himself as a person only as he knows himself as a sinner under God's forgiveness. Thus, the knowledge of sin is an occasion for acknowledging at once "the misery and the grandeur of man," and it is integral to personal existence. It is the antidote both to despair and to pride, and to the degradation of human culture that follows upon these twin evils.

Sin for Neo-orthodoxy is the violation of persons as seen in contrast to the love of God in Jesus for sinners. It is man's rebellion against his limited life and powers which comes both before and after his repudiation of responsibility, which in turn is the sign of death both for the individual and for the community. From it come dehumanization and the consequent evils of egotism, stupidity and guilt, as well as the loneliness, the loss of the meaning, anxiety, enmity and cruelty which plague human life. The Neo-orthodox defend such a view of sin as biblical and in line with a realistic knowledge of the condition of man.

4. Neo-orthodox criticism of modern culture led its theologians to examine political and economic institutions with a new awareness of their significance for responsible human existence. In this they have been influenced both by Marxist criticism of western capitalism and by new insights into the influence of social institutions upon personal life and relations. These theologians argue that religion, ethics, economics and politics are aspects of a larger whole which is the culture of a society, and that they cannot be understood and dealt with separately. Therefore, they assume a peculiar responsibility to concern themselves with social institutions and problems and to take a "Christian" attitude toward the controversial issues of the day, such as Communism, race relations and nuclear weapons. There is no unanimity among them as to answers to these perplexing public problems, but they are one in seeing the Word as addressed to the total present human situation.

Neo-orthodoxy is a political theology. It is illumined by politics and is a response to it. But it seeks to interpret politics in terms of biblical and Reformation theology: in terms of creation, sin and reconciliation, of God's self-revelation in Jesus Christ.

5. Neo-orthodoxy, especially in its European form, lays new emphasis upon the doctrine of the church as the community of believers. The church is spoken of as the Household of God, the Realm of Redemption, the Body of Christ. This phase of Neo-orthodoxy has been especially evident in the World Council of Churches where the several non-Roman churches have debated the nature and the responsibility of the church. Much has been written to the effect that the church is the place where God realizes in the world His saving work of restoring man to his true nature as person in community. These discussions have been once again biblical and according to traditional theology, but their empirical validity is apparently in doubt. Much has also been written which is strongly critical of the churches and presents them as dim lights in the world. There is no certain method by which the churches might become a more palpable influence toward the recovery of humanity. Thus a link is missing between theology and politics, and this, on the presuppositions of Neo-orthodoxy, is a great problem.

NEOPHYTE (Greek for "newly planted"), a word used exclusively by early Christians in the figurative sense (probably suggested by Rom. vi, 5, translated in the Authorized version "For if we have been planted together in the likeness of his death") of "one recently baptized." The term occurs once in the New Testament (I Tim. iii, 6, variously given in English Bibles as "neophyte," "novice," "convert newly baptized" and "recent convert") —an injunction against ordaining neophytes often cited by church writers and councils. The word is also common in epitaphs, notably on the sculptured sarcophagus, dated A.D. 359, of the Roman prefect Junius Bassus preserved in the Vatican grotto. By extension it came to be used to describe a newly ordained priest or a

novice in a convent, and, eventually, simply "beginner."
(M. H. Sh.)

NEOPLATONISM is the name given by historians of ideas to the last school of Greek philosophy (the ancient philosophers who are generally classified as Neoplatonists called themselves simply "Platonists," as did the philosophers of the Renaissance and the 17th century whose ideas derive from ancient Neoplatonism). After a long preparatory development it was given definitive shape in the 3rd century A.D. by the one great philosophical and religious genius of the school, Plotinus. From that time onward Neoplatonism dominated the thought of that dying ancient world within which the Byzantine and western Christian cultures were already coming to birth. Pagan Greek philosophy was Neoplatonist till it faded out in the 6th century A.D. Many of the greatest Christian thinkers of this period, the great formative period of Christian theology, were deeply influenced by Neoplatonism, as were later the great Muslim philosophers. The influence of Neoplatonism medieval thought was very great and has continued to influence men's minds. In modern times Neoplatonism was long despised and little understood; yet without some knowledge of this philosophy it is impossible to understand a great deal in the cultural tradition of Europe.

General Characteristics of Neoplatonism.—Neoplatonism began as an extremely complex philosophy and took varied forms in the course of its history, and it is therefore not altogether easy to generalize about it. But the leading ideas in the thought of philosophers who can properly be described as Neoplatonists seem always to include the following:

1. There is a hierarchy of reality, a plurality of spheres of being arranged in descending order, the last, lowest and least comprising that which exists in time and space, the being perceptible to the senses.

2. Each sphere of being is derived from its superior; this derivation is not a process in time or space.

3. Each derived being is established in its own reality by turning back toward its superior in a movement of contemplative desire, which is implicit in the original creative impulse of outgoing that it receives from its superior; so that the Neoplatonic universe is characterized by a double rhythm of outgoing to return. The movement of return is the most important, that which constitutes each level of reality.

4. Each sphere of being is an image or expression on a lower level of the sphere above it, and each individual reality an image or expression of a corresponding reality in the higher sphere. The relation of archetype and image runs through the whole of the Neoplatonic universe.

5. Degrees of being are also degrees of unity; in each subsequent sphere of being there is greater multiplicity, more separateness, increasing limitation of each reality till we arrive at the atomic individualization of the spatio-temporal world.

6. The supreme sphere of being, and so the whole of reality, is derived from a principle which as the source of all being cannot be described as being. "Being" to the Neoplatonist always means "being *x*," being this or that. Thus the inexhaustible source of being, which has no limitations, as it is not confined to being this or that but is in the fullest sense infinite, cannot be said to "be"; it is "beyond being." As it has no limitations, so it has no divisions, attributes or qualifications; it cannot really be named but may be called "the one" to designate its complete simplicity or lack of determination. It may also be called "the good" as the source of all perfections and the ultimate goal of return. For the impulse of outgoing to return that constitutes the hierarchy of derived reality is an impulse that comes from and leads back to the good.

7. The knowledge of this supreme principle is radically different from any other kind of knowledge because the supreme principle is absolutely simple and undetermined; it is not an object (a separate, determined, limited thing) and no predicates can be applied to it. It can be known only if it raises the mind to an immediate contact or union with itself, which cannot be imagined, described or defined.

Origins.—Whether the beginnings of Neoplatonism can be traced back to Plato himself is a question vigorously discussed by modern scholars. As always in the study of Plato, it is difficult to arrive at any sort of certainty. What does seem to be certain is that ideas which can be found in passages of Plato's dialogues (whether interpreted or not as Plato meant them) or in the scanty and obscure accounts of his later oral teaching are the root ideas of Neoplatonism. The most important are: (1) the basic Platonic doctrine of the two worlds, (*a*) the eternal and intelligible world and (*b*) the sense-world of time and change; (2) the idea that appears in one passage of Plato's *Republic* (509 B) that the principle of the eternal world, of the "forms" or "ideas" (*see* UNIVERSAL), is "the good . . . beyond being, surpassing it in dignity and power"; (3) the attempt made by Plato in his later teaching (about which very little is known) to derive the ideas by a logical-mathematical process from ultimate principles, namely "the one" (perhaps identical with "the good") and "the indeterminate dyad"; (4) the doctrine of a supreme divine intelligence, the relation of which to the ideas is not clear, but which forms and rules the sense-world according to their eternal order; and (5) the position of soul, human and cosmic, as intermediary between the two worlds, eternal and temporal, belonging to and able to operate in both. It seems to be becoming fairly certain, too, that Plato's immediate pupils and successors, Speusippus and Xenocrates, took some steps farther on the road that leads to Neoplatonism. This is particularly true of Speusippus; in the scanty fragments that survive of his teaching we find a "one beyond being."

Yet the beginnings of the continuous development that led immediately to the philosophy of Plotinus cannot be traced back beyond about the 1st century B.C. At that time certain philosophers—notably the stoicizing Platonist Antiochus of Ascalon, who revived dogmatic teaching after a period of skepticism in the Platonic school (*see* ACADEMY, GREEK), and the great Stoic Poseidonius, who was deeply influenced by Plato—inaugurated a type of thought that is found embedded in the vast confused works of Philo, an Alexandrian Jew of the 1st century A.D., and that was continued and developed into the 2nd century by the philosophers sometimes known as Middle Platonists and Neo-Pythagoreans, for instance Albinus, Atticus (*c.* 150–200), Plutarch of Chaeronea and Numenius of Apamea. The general characteristics of this revived Platonic or Pythagorean philosophy are the recognition of a hierarchy of divine principles and the stressing of the remoteness and transcendence of the supreme principle, which is sometimes called "the one"; the placing of the Platonic ideas in the divine mind; a strongly other-worldly attitude and a stressing of the necessity of the "flight from the body," the ascent of the mind to the divine and eternal; and a preoccupation with the problem of the origin of evil in this lower world, which is sometimes attributed to an evil world-soul (*e.g.*, by Plutarch) and sometimes to matter (by Numenius). Thus it obviously approaches very closely to the fully developed Neoplatonism of Plotinus, who worked out his own in some ways profoundly original philosophy on the basis of this already existing tradition.

Plotinus.—The history of Neoplatonism must be held to begin with Ammonius Saccas, the master of Plotinus, who was teaching in Alexandria in 232, when Plotinus came to him. But Ammonius wrote nothing and we know next to nothing of his teaching. So it is to the *Enneads* of his great pupil Plotinus that we must turn for our first evidence of authentic Neoplatonism. The *Enneads* are the primary document of the school, the foundation on which all later developments are built, and at the same time represent the summit of Neoplatonism's philosophical and religious achievement. In them may be seen the great leading ideas mentioned above in their strongest and simplest form.

The hierarchy of reality, in Plotinus, consists of only two great principles below the ineffable source (the One or the Good). The first of these two principles is intellect (*nous*), the divine mind which is identical with the totality of Platonic forms or ideas; it is the level of purely intuitive thought, immediate grasp of reality, which on the principles of Aristotelian psychology is identical with its object and so at once perfect intelligence and true reality, the cause of all less real derived beings. The individual realities in it (and there are forms of individuals as well as universals, and each one of us has his archetype in the world of

intellect) are at once forms and living minds which think and so, each in their own way, are the whole as well as parts. The second great principle is soul, which extends from the frontiers of the world of intellect to the last and lowest realities, the forms of material bodies. The characteristic of the life of soul is discursive reasoning, which proceeds from premisses to conclusions and does not immediately possess its object but strives to attain it. This restless rational movement of soul is the origin of time; intellect is beyond time in changeless eternity. Yet soul seems able to pass beyond rational-discursive thinking in both directions. On the one hand it can reach up into intellect, be fully illuminated and perfectly conformed to it and then ascend to the One; on the other hand the whole material universe is within the sphere of soul and is not only ruled but formed and animated by it, so that soul has a lower, immanent, unthinking activity that extends beyond even the limits of the organic, down to the forms of the lowest material things, as far as it is possible to go into the darkness of matter. No material thing can exist without a share in soul.

Thus Plotinus' view of reality, though hierarchic, is not complicated. The great realities, intellect and soul, have different aspects and many (though not infinitely many) members—and different levels on which those members can live. But Plotinus always maintains their essential unity, so as to keep close to the Platonic tradition as he received it and to his own philosophical experience. Moreover, the whole of his universe is open to and filled with the power of its first principle, the One or the Good beyond being. None of the realities that derive from it is cut off or separated from the One; it is immediately present to all of them according to the capacity of each to receive it.

The sole object of the good and wise man, the supreme goal of human endeavour, is to return to the Good and be united to it in the union of love which is beyond and above the contemplation of intellect, by the power coming from the Good, the impulse of return which is constitutive of his very being. First he must detach himself from the worldly desires and concerns of his lower self, the composite being of body and soul, by rigorous intellectual and moral discipline, inspired always by love and helped on his way at first by contemplation of the beauty of the world of the senses—which, rightly contemplated, will lead him back to the intelligible beauty of which it is a reflection. As he becomes perfect in intelligence and virtue (for Plotinus the two kinds of perfection are inseparable), the philosopher will rediscover his true and eternal self, which is intellect, or rather soul perfectly conformed to intellect, and wake to its life. Then he is ready to go on to the One when the One manifests itself and brings him to union.

Plotinus' philosophy, then, is not only theory but practice (a practice admirably exemplified in his own life). It is the union of theory and practice, of powerful metaphysical thinking with the continual stimulation to remember our true nature and return to our source. This accounts for its perennial power and attractiveness.

Porphyry and Iamblichus.—Plotinus' pupils were not of the same intellectual stature as their master, and in them can be seen the beginnings of the tendencies that were to become dominant with Iamblichus and that produced a considerable alteration for the worse in Neoplatonism. Very little is known about Amelius, the senior member of the school. External religious practice, the observation of feasts and sacrifices, was important to him as it was not to Plotinus, whose religion was entirely interior. In this Amelius points the way to later Neoplatonism; and he seems also to have begun the process of splitting up the levels of reality that was to lead to such fantastic complications later, by dividing the intellect of Plotinus into three. Of Porphyry, the biographer and editor of Plotinus, a good deal more is known; a number of his writings survive. He kept in most ways very close to the teachings of his master, but he was more interested in the details of practical asceticism, notably vegetarianism, on which he wrote a treatise. He was also a good deal more interested than Plotinus in the *daemones*, spirits intermediate between gods and men in whom Plotinus, as well as all ancient Platonists, believed, but who play no important part in his thought. Porphyry made evil *daemones* responsible for everything that was most repulsive and immoral in the practices of popular paganism, of which he strongly disapproved. He carried on the tradition inaugurated by Plotinus of polemic against the non-Hellenic religions that were steadily gaining influence, Gnosticism and orthodox Christianity. Plotinus himself, and his pupils in his lifetime, had written against Gnosticism, and Porphyry wrote 15 books *Against the Christians*. The work was destroyed by the Christian authorities in the 5th century, but quotations from it in Christian polemical writings allow us to suppose that it was the most powerful and intelligent of all pagan attacks on Christianity. Porphyry's hostility to popular paganism and non-Hellenic religion apparently did not extend, however, to pagan theosophy. He seems to have been the first philosopher to take seriously a theosophical farrago called the *Chaldaean Oracles*, composed late in the 2nd century A.D. by one Julian the Theurgist, which enjoyed unbounded authority among the later Neoplatonists, with most unfortunate results. But on the whole Porphyry remained reasonably close to the teaching of Plotinus, and his chief importance is as the disseminator and popularizer of Plotinian philosophy.

It was Porphyry's pupil Iamblichus who more than anyone else was responsible for the type of later Neoplatonism found in the schools of Athens and of Pergamum. Iamblichus, who died *c.* A.D. 330, moved back in later life from Rome, where Plotinus had established his school, to his native Syria; and from his time onward the chief centres of Neoplatonism were in the eastern half of the Roman empire—in Syria and at Athens, at Alexandria and at Pergamum. On the purely philosophical side, a distinctive characteristic of this Neoplatonism of Iamblichus (which continued to mark its later developments in the Athenian and Pergamene schools) was the tendency to multiply entities and to split up the levels of reality so that the hierarchic chain of being became continually longer and more complicated. Plotinus' hierarchic universe, as we have seen, was relatively simple and close to his own philosophic experience. He was content to allow ideas that might seem, on a superficial or too narrowly logical view, to be inconsistent to coexist in his reticent statements pointing us toward the ineffable source of being, the One or Good; and his great derived realities, intellect and soul, are rich, complex and many-sided. Plotinus, in short, though by no means a muddled thinker, would not seek clarity at the expense of truth. Iamblichus and his successors, while they were certainly anxious not to leave out any of the truth, also pursued perfect clarity and verbal coherence, at the price of no matter how many distinctions, with a fanatical unbalance characteristic of closed philosophical schools engaged in minute comment upon the works of established authorities. The basic assumption underlying their elaborations seems to be that the structure of reality corresponds so exactly to the way in which a late Greek philosopher's mind works that there is a separate real entity corresponding to every distinction that the mind can make.

Another characteristic of Iamblichean Neoplatonism adds considerably to its complications; viz., the apologetic motive, the desire to defend what Neoplatonists regarded as the true Hellenic tradition against its great (and now politically victorious) adversary Christianity. This motive, which had not been absent, as we have seen, from the school of Plotinus, soon became so strong that Iamblichus and his successors set out to construct a complete pagan theology. This means that they had to find a place in their system for every supernatural being in whom the pagans of the later Roman empire believed and, in particular, for all those mentioned by that very dubious authority for which Porphyry had opened a way into the school, the *Chaldaean Oracles*. This work indeed, now became a sort of inspired scripture, along with the dialogues of Plato (into which a remarkable amount of late pagan theology was read by vigorous allegorical interpretation). With this complicated theologizing and under the influence of the *Chaldaean Oracles*, there came into Neoplatonism the practice of theurgy, to which Iamblichus and most of his Athenian and Pergamene successors were enthusiastically addicted. Theurgy was a sort of higher magic aimed at producing an external communion with the gods. This was done sometimes by animating images, filling them with divine power by well-established Greco-Egyptian magical procedures; and sometimes by inducing the gods to possess a medium

and even to give visible manifestations of their presence, in ways strikingly reminiscent of modern spiritualism. This kind of thing was utterly alien to the spirit of Plotinus, who was certainly not a magician or a theurgist, though he was once persuaded to attend a theurgic séance (*see* Porphyry's *Life of Plotinus*, ch. 10); and Porphyry likewise, though he was persuaded by the *Chaldaean Oracles* to admit to some extent the real efficacy of theurgy, yet regarded it as a dangerous and dubious practice, useful at best to purify the lower part of the soul but quite unable to bring the true self to that union with God which he, as a true follower of Plotinus, regarded as the ultimate goal. From Iamblichus onward, however, most of the leading Neoplatonists were practising theurgists.

The Pergamene School.—The Pergamene school of Neoplatonism was founded by Aedesius, a pupil of Iamblichus; and the Pergamenes in general were, if anything, more wholeheartedly devoted to religious magic than the Athenians (though we hear of a strong protest against theurgy from Aedesius' pupil Eusebius of Myndus). Their most spectacular theurgist, Maximus of Smyrna, was the chosen master of the emperor Julian, who was converted from Christianity to Neoplatonism in its most superstitious and fantastic form and in whose short-lived pagan revival theurgists, Maximus himself and Chrysanthius, played an important part. The conversion of Julian, in fact, was the great achievement of the Pergamene school; his surviving writings are not of much importance philosophically, but they give a vivid idea of the religious spirit and outlook of Iamblichean Neoplatonism and its devotion to what it believed to be the ancient Hellenic tradition. Julian's death in 363 (after a reign of less than two years) and the restoration of Christianity as the state religion brought the Pergamene school to an end.

The Athenian School.—By the beginning of the 5th century the ancient school of Plato in Athens, the Academy, had become Neoplatonist; and there pagan Neoplatonism after the manner of Iamblichus survived nearly two centuries more under the Christian empire. The first outstanding teachers of this Neoplatonist Academy of whom we know were Plutarch of Athens and Syrianus; but far more important, at least for later generations, is Proclus (410–485), the great "scholastic" of Neoplatonism, who gathered and preserved in his voluminous works for such of posterity as might have the strength to read them every detail of Iamblichean philosophy as elaborated by his predecessors and by himself. The influence of his writings on Byzantine, Arabic and medieval Latin thinkers was considerable. After him a dim line of Platonic successors leads finally to Damascius and to the closing of the school by Justinian I in 529.

The School of Alexandria.—Later Neoplatonism, however, was not all Iamblichean elaboration and theurgy. Its exponents did not quite forget the authentic mystical doctrine of Plotinus, and the ideal of union with the One remained at least as a remote aspiration. In Athens, Proclus expounded the "negative theology" very adequately; and Damascius comes, at the beginning at least of his monstrous theological treatise, very close to the spirit of Plotinus. In Alexandria, moreover, a school developed in which little trace can be found of the influence of Iamblichus. The Alexandrian Neoplatonists were not given to metaphysical elaboration or addicted to theurgy. They were, first and foremost, scholars, learned commentators on the great philosophers of the past, and it is interesting to observe that they studied the works of Aristotle quite as much as those of Plato. In this they were following a tendency present in Neoplatonism from the beginning. There was already a very large Aristotelian element in the thought of Plotinus, though his own attitude toward Aristotle was generally critical; he had a low opinion of the philosophical importance of Aristotelian logic, though he admitted that it might have some usefulness as a preliminary study for the philosopher. Porphyry, however, was a good deal more Aristotelian (in this he was following a tradition already well established in the school—just as Plotinus' critical attitude shows the influence of an anti-Aristotelian tendency which appears in some Middle Platonists, notably Atticus) and, in particular, took Aristotle's logic very seriously. The great series of Neoplatonist commentaries on the *Organon* that was continued by the Alexandrian school was inaugurated by Porphyry's commentaries on the logical works and *Introduction to the Categories*—which furthermore were to play an important part in the development of medieval logic. It should be noted here that the greatest of the Neoplatonist Aristotelian commentators, Simplicius, though he was a member of the Athenian school, had been a pupil of the Alexandrian Ammonius Hermiae and is closer in spirit to his Alexandrian master than to his Athenian master Damascius.

The scholarly outlook of the Alexandrians and their lack of enthusiasm for the elaborate pagan theology and theurgy of the followers of Iamblichus made them much less hostile to Christianity than the Athenians (in spite of the murder of Hypatia by the Christian mob in 415). In the 6th century the commentator John Philoponus was converted to Christianity; and several of his contemporaries in the last generation of Alexandrian commentators, the pupils, like Simplicius, of Ammonius Hermiae, were Christians. Finally, in the 7th century, the last-known Alexandrian scholar, Stephanus, who was a Christian, was called to teach in the University of Constantinople under Heraclius. Stephanus forms one of the most important links in the chain of transmission of Platonism to the Byzantine middle ages.

Neoplatonism and the Christian Tradition.—In the Latin west there was no organized school of philosophy after Porphyry, but such philosophy as there was was Neoplatonist, and Neoplatonist in the manner of Plotinus and Porphyry rather than of Iamblichus. The Latin Neoplatonists included several people who, though not very original or important thinkers, had a considerable influence on western medieval thought. Some were pagans of a mild, scholarly and antiquarian sort; for instance, Macrobius (fl. *c.* 400) and Martianus Capella (early in the 5th century). Others were Christians; for instance, Chalcidius, the 4th-century commentator on Plato's *Timaeus* (he was really more a belated Middle Platonist than a Neoplatonist), and his contemporary the great convert rhetorician, translator and Christian Plotinian theologian Gaius Marius Victorinus, whose works and example influenced St. Augustine. More important than these was noble Boëthius, scholar, statesman, philosopher and theologian, who was executed by Theodoric in 524. His logical commentaries on Aristotle and Porphyry transmitted much of the learning of the Alexandrians in this field to the medieval west, and the influence of the book he wrote in prison, *On the Consolation of Philosophy*, was still deeper and wider. It was one of the books most read in the middle ages. King Alfred translated it into Old English.

But the most important achievement of Latin Neoplatonism was to bring the works of Plotinus and Porphyry to the notice of St. Augustine. He has told us himself in his *Confessions* how deeply they influenced him. Augustine had too great and original a mind simply to be labeled a "Christian Neoplatonist"; but it was through his writings more than through any other intermediary that something of the spirit and outlook of Plotinus was transmitted to the Latin middle ages.

In the east the great Cappadocian theologians, St. Basil and St. Gregory of Nyssa, read Plotinus and show some signs of his influence as well as of that of his great Christian contemporary Origen, whose thought sometimes shows striking parallels with that of Plotinus, perhaps due to the teaching of their common master Ammonius Saccas (if it really was the same Ammonius). Like St. Augustine, the Cappadocians are original thinkers and not merely servile copyists, and like him, too, they are Christians first and Platonists very much second; but through them also something of Plotinus passed into the theological tradition of the eastern and eventually of the western church.

Neoplatonic ideas also came into the Christian theological tradition through that most successful of pseudonymous writers "Dionysius the Areopagite," who expounded Christian mystical theology in the terminology and using some of the ideas of Proclus *c.* A.D. 500 and whose writings, with all the authority of their supposed author, St. Paul's Athenian convert, behind them, had an extraordinary influence both in the east and in the west. It was this influence of a diffused, diluted and transformed Neoplatonism in traditional Christian theology that was the most historically important part of the Neoplatonic contribution to European thought and culture.

This Neoplatonic influence can be detected in many places, not only in theology, in metaphysics, in logic and in moral philosophy but also in the early history of European science and of medieval and Renaissance art. From the 12th century onward it was reinforced in the west by the medieval Latin translations of Proclus and of the great Arabic philosophers who owed much to Neoplatonism; and from the 16th century onward the Greek texts of the writings of the Neoplatonist philosophers themselves became available in the west again (they had never been quite forgotten in Byzantium). But though the influence of these, and especially of the works of Plotinus, on those who read them has always been deep and lasting, the number of those who read them, even in translation, has been and probably always will be few; post-Renaissance Neoplatonism based on the original texts has been confined to select individuals and groups, of which one of the most important and attractive was that of the English Neoplatonists of the Cambridge school in the 17th century (*see* CAMBRIDGE PLATONISTS).

See also articles on many of the philosophers mentioned and references under "Neoplatonism" in the Index.

NEOPTOLEMUS, in Greek legend the son of Achilles and of Deidameia, daughter of King Lycomedes of Scyros; sometimes called PYRRHUS, "the fair." He was brought up by Lycomedes on the island of Scyros. In the last year of the Trojan War, Odysseus brought him to Troy, because the seer Helenus had declared that the city could not be captured without the aid of a descendant of Aeacus, who had helped to build its walls; Neoptolemus was Aeacus' grandson. He fought bravely and took part in the capture of Troy, but committed the sacrilege of slaying the aged king Priam at an altar. By Andromache, Hector's widow, he was father of Molossus, ancestor of the Molossian kings. He eventually married Hermione, daughter of Helen and Menelaus, and was shortly thereafter murdered at Delphi—by Orestes according to some versions of his story. He was buried there, and later worshiped on the spot as a hero.

NEOPYTHAGOREANISM is the name given by modern scholars to the revival of Pythagoreanism (*see* PYTHAGORAS AND PYTHAGOREANISM) which began in the 1st century B.C. and formed part of the development of Greek thought which led up to Neoplatonism (*q.v.*).

One of the principal forms which the literary activity of the Neopythagoreans took was the production of a large number of pseudonymous works attributed to Pythagoras himself or to early Pythagoreans, a method of procedure which did a good deal to obscure their own philosophical personalities. It is also impossible to draw a clear line of demarcation between Neopythagoreanism and the revived Platonism of the period, which is generally known as Middle Platonism. There had already been, of course, a strong Pythagorean element in Plato's own thought, and Pythagorean influence had become still more marked in that of his immediate successors in the Greek Academy, Speusippus and Xenocrates; and the systems of the Neopythagoreans often show clear traces of the influence of the latest, most Pythagorean phase of Plato's thought—his speculations about the ideal numbers and the ultimate mathematical principles of reality, the One and the indefinite dyad—and also of doctrines which developed later in the history of Platonism, notably the placing of the ideas or forms in the mind of God.

Neopythagoreans can be distinguished, as far as distinction is possible, from Middle Platonists in the following ways. They think of the eternal realities and cosmic principles as numbers rather than as forms or ideas (though ideas are often identified with numbers) and speculate extensively on the nature and properties of numbers and their origin from the One: in these speculations something like the Neoplatonic hierarchy of being begins to appear. Some of them lay great stress on an ascetic morality and way of living according to precise, allegedly ancient Pythagorean precepts, among which vegetarianism, based on the old Orphic-Pythagorean doctrine of the kinship of all living things, holds an important place. Some, too, show a strongly marked tendency to magic and occultism; *e.g.,* Publius Nigidius Figulus (Cicero's learned friend and the first Neopythagorean whose name we know) and Apollonius (*q.v.*) of Tyana.

Neopythagoreans who are philosophically interesting because they contributed to the developments leading up to Neoplatonism include the unnamed authors whose works were read by Alexander Polyhistor in the 1st century B.C. (according to Diogenes Laërtius viii, 25–35); Moderatus of Gades in the 1st century A.D. and Nicomachus (*q.v.*) of Gerasa in the 2nd, who developed Platonic-Pythagorean number-theory; and Numenius (*q.v.*) of Apamea also in the 2nd century A.D., whose system in some ways anticipates that of Plotinus. There are also two curious Neopythagorean political treatises by authors writing under the names of Diotogenes and Ecphantus, of which excerpts are preserved by Stobaeus (their date is uncertain, but probably about the 2nd century A.D.). These take a very exalted view of kingship, representing the king as cause of harmony and order in the state as God is in the world, and as a kind of mediator between God and men. Ecphantus, the more inflated of the two, who develops a kind of royalist quasi-mysticism, influenced Eusebius of Caesarea, so that his ideas passed into the thought of the Christian Roman empire.

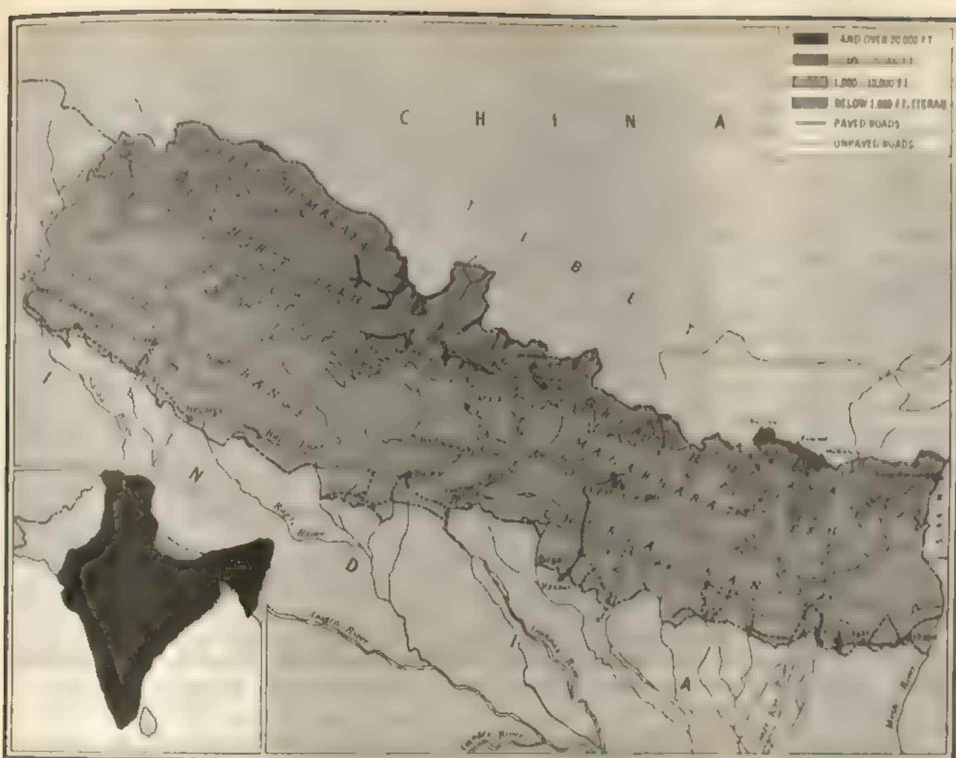
NEOSHO, a river of Kansas and Oklahoma, where it is also known as the Grand. The river rises about 20 mi. N. of Council Grove, Kan. This was Kaw Indian country and Neosho is a Kaw word meaning "wet bottom land." The crossing at Council Grove was the jumping-off point for the Santa Fe trail. There provisions were supplied for the long haul across the treeless plains. Flowing southward, the Neosho enters the Arkansas river near Ft. Gibson in Oklahoma. Erratic flow has limited development of the river. With a drainage area of 12,660 sq.mi., flow at its mouth varies from 133,000 cu.ft. per second to as little as 35 cu.ft. per second. Grand lake (Lake o' the Cherokees; 1,492,000 ac.ft. capacity) behind Pensacola dam is on the east edge of the Cherokee plain in Oklahoma and Ft. Gibson reservoir is near the junction of the Neosho with the Arkansas river. (C. N. C.)

NEPAL, an independent kingdom situated on the northeastern frontier of India, lying between longitude 80° 15′ and 88° 10′ E. and between latitude 26° 20′ and 30° 10′ N. Its extreme length is about 525 mi., and its breadth varies from 90 to 140 mi. It is bounded on the north by Tibet, on the east by Sikkim and West Bengal, and on the south and west by the Indian states of Bihar and Uttar Pradesh. Pop. (1961) 9,387,661. Area 54,362 sq.mi. The name Nepal is said to have been derived from the name of a saint Ne-Muni (Ne-pal, "the cherished of Ne"), who took up his abode near the confluence of the Bagmati and Vishnumati rivers. Originally applying only to the valley of Katmandu, it came to mean, with the Gurkha conquest, the whole of the territories at present incorporated in the state of Nepal. The capital is Katmandu.

Physical Geography.—Except for a narrow strip along the southern border, Nepal lies entirely within the great mass of the Himalayas. It is divided by altitude into three distinct zones: (1) The Terai, a strip of comparatively level country at the foot of the mountains, formerly consisting almost entirely of jungle and swamp, but of which large areas have now been brought under cultivation, and the low-lying valleys or Duns situated between the low Siwalik or Churia range of hills and the



TOPOGRAPHY AND MAJOR CITIES OF NEPAL

habharat Lekh of the Himalayas, which may be included with the Terai; (2) the central mountainous belt, varying in altitude from 1,000 to 8,000 ft.; and (3) the alpine zone, comprising the higher slopes and valleys of the main Himalayan range and the trans-Himalayan districts of Manangbhot, Mustangbhot and Charkhabhot. The backbone of the Nepalese Himalayas contains many of the highest mountains in the world; from east to west there are: Kangchenjunga (*q.v.*; 28,168 ft.); Makalu (27,790 ft.); Everest (*q.v.*; 29,028 ft.); Cho Oyu (26,750 ft.); Manaslu (26,-658 ft.); Himal Chuli (25,801 ft.); the Annapurna (*q.v.*) massif, which extends for more than 30 mi. and terminates in the east in Annapurna II (26,041 ft.) and in the west in Annapurna I (26,-391 ft.); Dhaulagiri (26,790 ft.); and, in the extreme west, Api (23,399 ft.). From this great range, which runs roughly from northwest to southeast, two lesser but still formidable ranges run roughly southward from Dhaulagiri and Gosainthan.

These ranges divide the country into four distinct regions. The western region extends from the Sarda, or Mahakali, river, which forms the frontier with Kumaon in the west, to the Dhaulagiri range and comprises the basins of the Karnali and Bheri, or Surju, and the greater Rapti, all of which combine to form the Gogra, which eventually flows into the Ganges. The central region comprises the basin of the Gandak and its tributaries the Narayani, or Kali Gandaki, the Seti, the Marsyandi, the Darondi, the Burhi Gandak and the Trisuli—the Sapt Gandaki (Seven Gandaks) of the Nepalese, which unite and flow out of Nepal near Tribeni Ghat and also join the Ganges. The great southern offshoot from Gosainthan bifurcates to form the third region, the elevated valley about 12 by 15 mi., the true Nepal, or valley of Katmandu, lying at an elevation of slightly more than 4,000 ft. and surrounded by mountains, which rise in places to 9,000 ft. and through which there is but one outlet, the gorge through which the holy Bagmati flows. To the east lies the fourth region, which is formed by the basin of the Sapt Kosi draining the mountains from Gosainthan to Kangchenjunga and including the Indrawati, the Sun Kosi, the Dudh Kosi, which flows down from Everest and Namche Bazar, the Arun and the Tamur. These rivers combine and flow into India not far from the Nepalese town of Biratnagar, where, as they debouch into the level plains, the almost annual floods used to cause havoc. To prevent this, the building of a barrage has been undertaken partly in India and partly in Nepal. The eastern frontier with the Darjeeling district of India is formed by the Singelala range running south from Kangchenjunga and the small Mechi river, which, although insignificant in itself, gives rise to the expression "from the Mechi to the Mahakali" denoting the whole of Nepal. Before consolidation of Nepal under the Gurkha power, the central region consisted of a number of independent principalities known to the Gurkhas as the Chaubisia, or Twenty-four Kingdoms; likewise the western region consisted of another 22 principalities known as the Baiisi Raj.

Climate.—The whole of Nepal is subject to the monsoon, but the climate varies greatly with altitude. The low-lying Terai has a subtropical climate and a heavy rainfall, hot in the summer, very humid during the monsoon but pleasantly cool in the winter. The central hills and the alpine zone have a pleasant summer, a cold winter with heavy snowfalls above 8,000 ft., and a monsoon in which the rainfall varies greatly from one valley to the next.

Vegetation and Animal Life.—The vegetation and animal life also vary considerably with altitude. In the Terai the most important tree is the sal (*Shorea robusta*), which provides a hard and durable timber. Other trees are the silk-cotton tree (*Bombax*) and dhak (*Butea frondosa*), which make the jungles beautiful in the spring with their red and flame-coloured flowers. The lower slopes of the central mountainous zone are for the most part heavily cultivated, but the chir pine (*Pinus roxburghii*) grows in places. Above the cultivation, from about 7,000 to 10,000 ft., are forests of oaks, including *Quercus lanuginosa*, *Q. semecarpifolia* and *Q. lammelosa*, while the rhododendrons, which grow from 5,000 to 12,000 ft., sometimes in dense forests and in many varieties, provide a magnificent show of flowers in the spring. Scattered through the forests are magnolias and wild cherry, wild pear, barberry (*Berberis*) and *Daphne*. There are many orchids, ferns and other wild flowers. In the alpine zone exist varieties of conifers, the silver fir, blue pine, juniper, yew, hemlock and also birch, dwarf rhododendron and other alpine flora, including primulas of many varieties, while in the higher and drier regions grows the blue poppy.

In the uncultivated parts of the Terai are vast jungles, the home of tiger and leopard, gaur or wild ox, occasional elephants and buffalo, and many deer: chital or axis deer, sambar and swamp deer. In the valley of the Lesser Rapti in the district of Chitawan is one of the last homes of the great Indian rhinoceros (*Rhinoceros unicornis*), of which only about 700 are believed to exist, 300 of these being in Nepal. Much poaching has gone on as the horn of the rhinoceros is reputed to be valuable as an aphrodisiac, but the Nepal government was, in the 1960s, organizing protective measures.

There are few wild animals in the central zone because of cultivation, extensive woodcutting and grazing in the forests. Occasional leopards, bear and the smaller carnivores inhabit the forests and ravines, and muntjac are found in the woods. In the alpine zone are musk deer, much persecuted for the musk pods it carries, the tahr and goral wild goats, and wild sheep, which are preyed upon by wolves and snow leopards. Pheasants are common, the kalij in the central hills and the magnificent monal, tragopan and blood pheasant in the alpine zone. The Yeti (bear-

man or Abominable Snowman, *q.v.*) is said by the Sherpas to inhabit the high snow mountains but has eluded discovery by several expeditions that have set out to solve the mystery of this fable. Strange tracks are often found in the snow, but opinion inclines to the belief that they were probably made by bears searching for new foraging grounds. River fauna includes the mahseer.

History.—In the early history of Nepal it is difficult to distinguish fact from legend, and dynasty succeeds dynasty with little apparent reference to historical time. According to legend, the valley of Nepal was once a lake that was drained by the saint Manjushri (Manjusri), who came on a religious pilgrimage from China and, striking the earth with his sword, opened the gorge of Chobar ("sword-cut"), through which the river Bagmati now flows. Having drained the valley, he returned to China, leaving his disciple Dharmarkar as the first king of the country. Many succeeding dynasties followed until Dharma Dutta is reported to have come with a conquering army from Conjeeveram (Kancheepuram), in south India. Gautama Buddha reputedly was born at Lumbini (*q.v.;* Rummindei, or Rupindei), which, although not in the valley of Nepal proper, is now in the Nepalese Terai. About 250 B.C. Asoka is said to have visited Nepal, where his daughter settled and founded Deopatan near the present shrine of Pashupati (*q.v.*). In the 5th century A.D., under King Mana Deva, commerce flourished, and trade with India and Tibet enriched the country. The pillar at the shrine of Changu Narayan, dated 496, records the successes of this reign. In about 606 began the reign of Amshuvarman, who founded the Thakur dynasty. He gave his daughter in marriage to the powerful Tibetan king Songtsen Gampo (Srong Btsan Sgampo), who also took a wife from China, and the two Buddhist queens converted their husband and are thus credited with introducing Buddhism into Tibet; they are famous to the Nepalese as the two Taras. Narendra Deva, the seventh king of this dynasty, is said to have brought the saint Machendra, deeply revered until the present day, into the valley. It was during his reign also that the first Chinese mission came to Nepal, and many pilgrims are said to have visited the valley, attracted by its reputation for piety and its connections with Buddha. Yaksha Malla, who is thought to have reigned from 1429 to 1460, annexed Morang, Tirhut, Gaya and Shekar Dzong in Tibet. He divided the country into four kingdoms: Bhadgaon, Katmandu, Banepa and Patan, giving one each to his three sons and daughter.

Little is known of the ancient kingdom of Gurkha (*q.v.*), but tradition and legends say that the ruling family was descended from the Rajput princes of Udaipur, who had been driven out of their own country by the Muslims and who moved into the Himalayas and settled down to set up their own principalities. In 1742 the able and ambitious Prithvi Narayan Shah (*q.v.*) came to the throne and took up arms against the Nepalese kingdoms. After many failures he was able, through the internal dissensions of the Malla kings of Katmandu, Bhadgaon and Patan, to subjugate the valley and brought it finally under his rule in 1768. He moved his capital to Katmandu, and for the first time the term "Nepal" began to denote more than the mere valley and the three towns. The Gurkha armies then turned east and west, extending their territories to Sikkim and subduing many of the principalities of the Chaubisia Raj. Prithvi Narayan died in 1775, but his successors continued to expand, conquering Sikkim and advancing in the west as far as the Kangra valley in Punjab, where they were brought to a stop by the power of Ranjit Singh of the Sikhs. An invasion of Tibet, which took the Gurkha armies to Shekar Dzong, brought on a war with China in which the Gurkhas were driven back to Nepal, and in 1793 a peace was concluded by which Sikkim and the conquests in Tibet were relinquished. Since 1787 there had been increasing friction with the British, culminating in the seizure of some of the territories administered by the East India company, which led to the Gurkha War of 1814–16. After some initial reverses British forces led by Gen. Sir David Ochterlony conducted a successful campaign, and a treaty of peace was signed by which the Gurkhas withdrew into approximately the present bounds of Nepal and agreed to accept a British envoy in Katmandu. The war was fought with gallantry and chivalry on both sides, and the two countries have remained close friends ever since.

After the Gurkha War, there followed a period of intrigue and internal dissensions in the court, which led to the rise of an able prime minister, Bhimsen Thapa, who virtually ruled the country through the minority of the king. He himself eventually fell victim to intrigue, and the court relapsed into a further period of dissension, which culminated in 1846 in the massacre of the Kot (the royal court of assembly) in which many of the leading noblemen were killed. A young but able soldier, Jung Bahadur, the grandnephew of Bhimsen, then became prime minister. Intrigues against his life led Jung Bahadur to banish the king and queen and to place the minor heir on the throne. Later he was appointed hereditary prime minister, an office which was to remain in his family until 1951. Jung Bahadur visited England in 1850–51 and remained a firm friend of the British, sending his troops to help them during the Indian mutiny. He died in 1877. Gurkha troops continued to serve as part of the Indian army until India's independence in 1947, and the existing regiments were then divided between Britain and India. In 1923 the treaty of Sagauli (1815, ratified 1816) between Nepal and Britain was replaced by a treaty of friendship by which Britain recognized the complete independence of Nepal.

By the end of World War II the Rana family had been ruling in Nepal for more than 100 years, and the time for change had come. Nepalese students in India had come in contact with democratic ideas, and in 1946 the Nepali Congress party was formed by the brothers Koirala. Not only were the people stirring against the autocratic rule of the Ranas but King Tribhuban (Tribhuvan), who had received a liberal education from tutors, determined to take his place as a constitutional monarch and in Nov. 1950 left his palace to take refuge in the Indian embassy, from where he was allowed to proceed to India. A revolution headed by the Nepali Congress broke out, and early in 1951 terms were agreed on between Maharaja Mohan and the Congress leaders by which a ten-man cabinet, composed half of Ranas and half of the Nepali Congress, assumed the government. King Tribhuban returned to Katmandu as a constitutional monarch on Feb. 18, and democracy had come to Nepal. In November 1951, finding that the mixed cabinet did not work, Maharaja Mohan, the last of the hereditary Rana prime ministers, resigned, and M. P. Koirala formed a government entirely from the Nepali Congress party. It had not yet been possible to hold an election, and during the next eight years there was a succession of more or less ineffective governments. King Tribhuban died in 1955 and was succeeded by his eldest son, the crown prince Mahendra Bir Bikram Shah Deva. The new king was determined to press on with preparations for an election and assembled a committee to draw up a constitution. The first election was held in 1959 and the new constitution brought into force. The Nepali Congress won a clear majority with 74 out of the 109 seats, the Gurkha Parishad with 19 forming the official opposition. Parliament was assembled for the first time in the autumn, with B. P. Koirala as prime minister.

In Dec. 1960, King Mahendra dissolved parliament, suspended part of the constitution and took over the administration himself. The reason given was dissatisfaction with the inefficiency and corruption of the government, which had created restlessness among the people. Later the king formed a council of ministers with himself as chairman, and all political parties were banned in Jan. 1961 by a proclamation, which also outlined the king's proposals for building "basic democracy" from the bottom, starting with village councils (*panchayats*). Relations with India, at first strained, improved, and, in April 1961, agreements were signed providing for continued Indian aid on a substantial scale for a wide range of development plans. The king visited Pakistan in Sept. 1961 and, later, Peking, where, in October, he signed an agreement with the Chinese People's Republic defining the boundaries between Nepal and China. A renewal of unrest occurred from Dec. 1961, and in Jan. 1962 a bomb was thrown at the king's car while he was on tour. In Feb. 1962 elections to village *panchayats* were held. In April 1962 the king paid an official visit to India, and the establishment was announced of an Indian-Nepalese committee to investigate Nepalese charges that India was supporting Nepalese rebels. In Dec. 1962 a revised constitution was an-

nounced, based on an indirectly elected single-chamber legislature known as the National *panchayat* (inaugurated April 1963).

The People.—The origin of the present peoples of Nepal is obscure, but it seems that a movement of Mongoloid peoples from the north met a movement of Aryan peoples from the south and west and that the resulting intermingling produced the present tribes. At a considerably later period there was a further influx of people of Rajput stock, who, driven out of their homes in India by the Muslims, drifted up into the hills, where they settled and to some extent intermarried with the local tribes. In the central mountainous zone the mixture of the tribes is most apparent. Throughout the length of Nepal in the lower valleys will be found the Brahmans and Chhetris (Chetris), who are perhaps a more recent mixture of the later Rajput invasion and the local tribes. Both Brahmans and Chhetris are strict adherents of the Hindu religion. The Chhetris belong to the warrior or Kshattriya caste and freely enlist in the army. Higher up the mountain slopes are Magars and Gurungs, two tribes of distinct Mongoloid origin and of famous fighting stock. In the hills surrounding the valley of Katmandu and extending east and west are the Tamangs, or Lamas, and farther east are the Rais, the Sunwars and the Limbus, also with great martial traditions. The religion of these Mongoloid tribes varies. The Magars incline toward the Hindu faith, and the Tamangs to the Buddhist. The Gurungs, Rais and Limbus have their own priests, and rites and ceremonies, at any rate within Nepal, incline more toward Buddhism than to Hinduism; away from home they tend to follow the predominant Hindu rites. In the alpine zone, tribes of more recent Tibetan derivation are found, the Sherpas in the east with their centre around Namche Bazar, and to the west the Bhotias, closely akin to the Sherpas and Tibetans. The chief population centres are Katmandu, Bhadgaon (*qq.v.*) and Patan. (RI. R. P.)

Newar Culture.—Until the end of the 18th century Nepal was all but limited to the central Nepal valley with its main cities of Katmandu, Patan, Bhadgaon and Kirtipur. The inhabitants were the Newars (who speak Newari), and in this enclosed area a remarkable Hindu-Buddhist culture began to develop, probably in the 4th century. The earliest historical records are stone pillars dating from the 5th century onward. Sanskrit was introduced as the literary and religious language, and the Nepal valley rapidly developed into a strong outpost of medieval Indian culture. Buddhism disappeared from India about the year 1200, but its elaborate forms have continued in Nepal up to the present time. In Katmandu are preserved the largest collections in the world of ancient Indian manuscripts. The remarkable pagoda temples so typical of Nepal are in fact descended from earlier Indian models; similar survivals exist in Kulu and the Sutlej valley and in Kerala. Newar craftsmen became famous for their wood carving, sculpture, metalwork and religious painting, and many of their crafts still survive. The Tibetans have been much indebted to Newar craftsmen in the past, and up till the Communist Chinese military occupation (1959) there was still an active Newar community of merchants and craftsmen in Lhasa. (D. L. SN.)

Languages.—Nepali (sometimes called Khaskura, Gurkhali or Parbatiya), the language of the Brahmans and Chhetris, is of Sanskrit derivation and has become the *lingua franca* of Nepal, but the Mongoloid tribes and the Newars have their own languages, which belong to the Tibeto-Burman group.

Administration and Social Conditions.—The constitution, promulgated in Dec. 1962, introduced a *panchayat* (council) system in four tiers, which was designed to enable the people at all levels to take part in the improvement of the country. At the lowest level is the village assembly (*gaun sabha*), representing a village or group of villages, of which all the villagers above 21 years of age are members; this assembly elects a nine-member executive, the village *panchayat*, whose function is to prepare and carry out plans for village improvement, and which can levy certain taxes. There are more than 3,500 village *panchayats* in the country. Urban areas have an elected council (*nagar panchayat*); there are 14 of these. The second level is the district assembly (*zilla sabha*), composed of representatives of the village and town *panchayats*, with its 11-member executive, the *zilla panchayat*, of which there are 75 in the country. This body can also levy taxes. It is also responsible for implementing government plans at district level, with the assistance of technical officials. The third level is the zonal assembly (*anchal sabha*), of which there are 14, and consists of the members of the district *panchayats* in the zone. It selects its own executive of 11, and also members of the national (*Rashtrija*) *panchayat*, which is the highest level and is in fact the national legislature. The national *panchayat* has a single chamber and consists of 125 members who are elected for four years, except for those elected by *anchal* assemblies, who serve for six years. One-third of the members retire every two years.

The council of ministers and its chairman are appointed by the king from the members of the national *panchayat*, and the council is responsible both to the king and to the *panchayat*. Fundamental rights conferred on the people include personal liberty, equality before the law and religious freedom.

The local *panchayats*, with their planning functions, are intended eventually to replace the administrative system also. For purposes of local government the country is divided into 38 districts, each under a Bada Hakim, who is responsible for all local administration. At each district headquarters is the district court and also an appeal court. There are three high courts, one in the east at Biratnagar, one in the centre at Katmandu and one in the west at Nepalganj, to which further appeals may be taken. There is also a supreme court in Katmandu to which certain appeals may be taken, and which is empowered to declare invalid any law not consistent with the provisions of the constitution.

Taxation is light, and there is no income tax. Revenue is raised chiefly from a land tax and from customs duties. A house tax for larger houses has been introduced, and the tax-free land tenure has been abolished.

The standard of living on the whole is low, but stark poverty is rare, the people generally being well fed, clothed and housed though there is little surplus. In the countryside little money passes, most families being more or less self sufficient. Houses are well built, usually of mud brick, coloured with red or white earth, and have two stories and generally a thatched roof.

Health and social services are in a rudimentary state, but in the early 1960s a mission from the World Health organization was assisting the government to improve health services and was running a school for medical assistants to work in the districts. There are state hospitals in Katmandu, Biratnagar and Nepalganj, but medical services were lacking outside the main centres. In Aug. 1963 a law code that abolished polygamy and child marriage and made all castes equal came into force.

The standard of education is low and illiteracy is widespread, but great efforts are being made to establish primary schools throughout the country. Katmandu and some other main centres have high schools, and in Katmandu, Tri-Chandra college prepares students for the external degrees of Patna university. Tribhubana university was established in 1958 and gives its own degrees. English is the principal medium of instruction.

The army consists of one division of infantry with a few supporting and ancillary units. There are, however, considerable reserves of trained men in the country, and expansion could be rapid. An armed police force is maintained for use in case of civil disturbance, and the normal civil police are organized throughout the districts.

The Economy.—Nepal is an agricultural country with few industries. The mountainous nature of most of the territory makes agriculture difficult, while the lack of communications hampers the development of industries and trade. In the greater part of the country the people live by subsistence agriculture, producing their own food and most of their requirements. Cloth and a few simple consumer goods are imported through India. A five-year plan (1956–60) was implemented to develop agriculture and industry. Aid for this plan was received from a number of more developed countries. A four-year plan (1962–65) followed with emphasis on communications, electrification and industry.

Agriculture.—In the Terai the main crop is rice. Most of the surplus rice is sent to the valley of Katmandu, where there is a deficit, but some of it is exported to India. Jute is grown in the

eastern districts of Morang and Jhapa, and there would appear to be possibilities of increasing this crop considerably. In the densely populated valley of Katmandu every available piece of ground is heavily cropped with rice in the monsoon season and with wheat or vegetables in the winter and dry months. The main crops in the hills are maize (corn), millet and pulses, which are grown on the carefully terraced hillsides; rice is grown in the valleys wherever it is possible to bring an irrigation channel. Comparatively few animals are kept as there is little cultivable land that can be spared for them, and they must graze on the rough hillsides. Buffalo and cows reared for milk are largely stall fed, but the Gurungs in the western hills keep flocks of sheep that feed on the high mountain slopes in summer and move down in winter to the rough and uncultivable areas in the lower hills. For the most part Nepal receives a sufficient rainfall, but in a few districts in the hills and in the central Terai the monsoon is sometimes scanty or untimely, and acute hardship, if not actual famine, results. In the alpine zone the Sherpas keep chaunries, a cross between the yak and hill cattle, for the production of butter. Surplus butter has been exported to Tibet, but efforts have been made to encourage the making of cheese that can be exported to India.

Forestry.—The main forest product is sal timber from the forests of the Terai, which is much in demand in India. In the past, forests have been mismanaged and severely damaged by indiscriminate cutting, but in the 1960s steps were taken to conserve them and to develop this industry, which brings in an appreciable revenue to the state.

Mining.—In various places in the hills small deposits of ochre, copper and iron are found, some of which are worked by primitive methods to produce simple utensils and agricultural tools, but these meet only a small part of the demand. A geological survey under the auspices of the United Nations Technical Aid administration was being carried out in the early 1960s. Deposits of hematite iron ore have been found on Phul Chowk, a 9,000-ft. mountain near Katmandu, but difficulties of extraction and the provision of fuel for smelting make it doubtful if these could be worked economically. A few deposits of soft coal exist, but their exploitation has so far not been found worthwhile. The main impediment to the development of mineral products is the difficulty of the terrain and the lack of communications.

Power.—Nepal has a vast potential for the production of hydroelectric power, which up to the early 1960s had hardly been tapped. Small hydroelectric plants exist near Katmandu for the production of electricity for the capital, and these are being further developed. The Kosi project, a joint project between Nepal and India for the control of the waters of the Kosi river by building a barrage on the river at the point where it crosses the Indian frontier, was planned to produce about 20,000 kw., half of which will be available to Nepal; and India, under the Colombo plan, is planning the construction of a hydroelectric power station at Trisuli, about 35 mi. from Katmandu, which when built will produce 18,000 kw. But this has hardly scratched the surface, ample water power being available in almost every district of the country.

Industries.—There has been very little industrial development beyond a few rice, jute and sugar mills at Biratnagar and rice mills at Birganj. Cement production near Hitaura, a tobacco factory, paper mills to deal with an indigenous grass that forms a suitable raw material and the modernization of the Biratnagar jute mills were planned.

Trade and Finance.—Internal trade is mostly concerned with the supply of the few consumer goods that the population can afford and is carried on by small shopkeepers rather than by large trading organizations. Practically all imports and exports pass through India. Imports consist of manufactured consumer goods, while exports are timber, rice and a small quantity of jute and wool. A small barter trade in rice and salt is carried on with Tibet.

There are two banks in Nepal, the Rashtriya (National) bank, concerned in government business, and the Nepal bank, which deals with ordinary banking business. The currency is the Nepali rupee, which had fluctuated in value but in the 1960s was maintained at a rate of 160 Nepalese to 100 Indian rupees.

The country is poor, and taxes are necessarily low. The budget is divided into two parts, that of ordinary expenditure and that for development. The main items of revenue are customs duties, land revenue, and forests. The development budget was supported by grants-in-aid from countries assisting in the development of Nepal.

Transport and Communications.—Good roads are few. A motor road runs from Raxaul on the Indian frontier to Katmandu, about 130 mi., and another from Jogbani to Dharan, about 30 mi. Under the tripartite road agreement between Nepal, the United States and India, a road was begun from Katmandu to Trisuli Bazar, and other roads were planned. A narrow-gauge railway about 30 mi. long runs from Raxaul to Amlekhganj and another from Jaynagar to Janakpur. The railhead at Amlekhganj was linked by truck road with Dhursing, thence by ropeway (electrically operated aerial cableway) to Matatirtha in the Nepal valley and thence by trolley line to Katmandu. A larger ropeway from nearer Amlekhganj to Katmandu was constructed in the 1960s. Katmandu has an all-weather landing ground, but low clouds can prevent the approach of aircraft to the valley. Other landing grounds are at Biratnagar, Rajbiraj, Simra, Narayangarh, Dang, Nepalganj and Pokhara, all of these being fair-weather grounds and all except Pokhara being in the Terai.

Radio Nepal at Katmandu broadcasts in Nepali, Hindi, Newari and English. Nepal has joined the International Postal union, and postal and telegraphic services are maintained with the rest of the world. (Ri. R. P.)

NEPALI LITERATURE. Before the Gurkha (*q.v.*) conquest in 1768, Nepalese writings were in the Sanskrit, Newari and Nepali (also called Khas-kurā, Parbatiyā and Gurkhali) languages. They consisted of religious texts, chronicles, gift-deeds, etc. Extant material in Nepali, with the possible exception of the memoirs of the Gurkha king, Pṛthvī Nārāyaṇ Shāh (*c.* 1770), has historical but not literary interest. Literary writing in the language only began in the 19th century.

About 1830 a school of poets appeared which included Vasanta Sharma, Vidyāranya Keshari and Indiras. They wrote on themes from the *Rāmāyaṇa* (*q.v.*) and the *Bhāgavatapurāṇa*, in a language that is more Sanskrit than Nepali. They were followed by Bhānubhakta (1814–69), whose version of the *Rāmāyaṇa* achieved great popularity for the colloquial flavour of its language, its religious sincerity, its patriotic fervour and its realistic natural descriptions; and, later, by Lekhnāth Pauḍyāl (b. 1884) who also tended to the colloquial and used the rhythms of popular songs in some of his poems.

Printing in Katmandu, the capital of Nepal, dates from the 1860s, and there were presses also in Varanasi (Benares) and Darjeeling. The *Gorkhā Patra*, Nepal's first newspaper, began in 1901; educational books appeared, and *Candrikā*, the first indigenous Nepali grammar, was published in 1912. The age of modern literature, however, really began in the 1920s with the institution of the *Gorkhā Bhāsāprakāśinī Samiti*, and owes much to two brothers, Bālkṛṣṇa (b. 1903) and Puṣkar Shamsher (1902–60). The former wrote plays based on Sanskrit and English models, lyric poetry and some short stories; the latter, a teacher, lexicographer and grammarian, was a short-story writer and translator from English. Their contemporaries were the poets Lakṣmīprasād Devkoṭā (1908–60) and Siddhi Caran (1912–) and the prose writer Bhīmnidhi Tivārī (1911–). Modern poets have discarded the earlier Sanskrit-dominated tradition in favour of themes more suited to the ideologies of their new democracy, and have imitated 20th-century European and American verse, though Devkoṭā also used the popular *jhyāure* metre. Their diction, however, is often artificial and their thoughts ob-

scure. By the 1960s modern Nepali literature had produced only minor poets, but in the short story some authors had achieved a measure of success.

Newari, the mother tongue of more than half the population of the Katmandu valley (*see* PAHARI LANGUAGE), and the court language until 1769, was denied literary expression until censorship began to relax in the 1940s. Since then many Newars have written and published, and in the 1950s one, Cittadhar "Hrday" (1906–), achieved considerable local reputation.

In the past many scripts were used in Nepal, including *devanāgārī*; the various scripts of Newari; and Tibetan. The modern press uses only the *devanāgārī*, for Newari and Nepali alike.

See Bāburām Ācārya, *Purānā Kavi Ra Kavitā* (1946).

(T. W. CL.)

NEPHELINITE is a basic lava, usually completely crystallized, in which the essential minerals are nephelite and pyroxene.

Known only from Tertiary strata, nephelinites are abundant in the Canary Islands, the Azores, the Cape Verde Islands and Fernando De Noronha Island off the coast of Brazil. Specimens from the Eifel and Kaiserstuhl regions in Germany are staples in petrographic collections, as are those from central Bohemia and the Odenwald (Katzenbuckel). They are on the whole not common in the Mediterranean area, but leucite-bearing representatives are known from Monte Vulture in Italy and Tripoli in north Africa. Nephelite-rich basic lavas are perhaps most extensively developed in east Africa, especially in the Somali Republic and Masai-land (in Kenya) and also in Nigeria. In the United States they are best known from the Big Bend region of west Texas, the Bearpaw mountains, Mont., and Cripple Creek, Colo.

The pyroxene in nephelinites may be either titan-augite or aegirine; plagioclase, if present, is commonly labradorite. Varieties rich in leucite and haüyne are well known. Biotite is characteristic in some types; amphibole is scarce. Accessories may include sanidine, melilite, melanite, sodalite, perofskite, pseudobrookite, apatite and chromite.

The nomenclature of these nephelite-rich basalts is confusing but firmly established. The plagioclase-free varieties are called nephelinite if they also lack olivine, nephelite-basalt if olivine is an essential constituent. The plagioclase-bearing varieties are called nephelite-tephrite if they lack olivine and nephelite-basanite if olivine is an essential constituent. They are otherwise similar in mineralogy, appearance, structure and occurrence. The relative abundance of the plagioclase-free and plagioclase-bearing members of the group is a matter of conjecture, as is the quantitative importance of the group as a whole vis-à-vis more normal (*e.g.*, nonfeldspathoidal) basalts. About all that can be said is that, despite their wide geographic distribution and occasional extensive local development, they are very rare rocks.

(F. Cs.)

NEPHELITE, or NEPHELINE, a rock-forming mineral consisting of sodium, potassium and aluminum silicate, is an essential constituent of certain older alkaline plutonic rocks, such as the nephelite-syenite of southern Norway. Commercial quantities of nephelite-syenite occur in Ontario, Can., and the nephelite, because of its high alumina content, is used in the manufacture of glass and ceramic products as a substitute for feldspar.

Nephelite is commonly associated with feldspar, sodalite, cancrinite, biotite, corundum and zircon; never with primary quartz. Two varieties are distinguished. Nephelite proper is glassy, light coloured and frequently in crystals. It is common in recent eruptive rocks rich in alkalies, such as phonolite, nephelite-basalt, leucite basalt, etc., and also certain dike rocks such as tinguaite. The best crystals occur with mica, sanidine and garnet in the crystal-lined cavities, or vugs, of the ejected blocks of Monte Somma, Vesuvius. The other variety, eleolite, occurs as rough crystals or irregular masses, which have a greasy lustre, and are translucent or nearly opaque, with a red, green, blue or brown colour.

Nephelite has the approximate formula $Na_6K_2Al_8Si_9O_{34}$. Artificial crystals can be made with the composition $NaAlSiO_4$, but the natural material always contains some potassium and an excess of silica. Nephelite crystals are hexagonal, usually in the form of short six-sided prisms terminated by a basal pinacoid. The specific gravity (2.6), the low index of refraction and the feeble double refraction are nearly the same as in quartz, but it is optically negative, while quartz is positive, and the hardness is only 5.5, in contrast to 7 for quartz. Nephelite is easily decomposed by hydrochloric acid, with separation of gelatinous silica and formation of cubes of salt upon evaporation. A clear crystal of nephelite when immersed in acid becomes cloudy for this reason; hence the name, from the Greek meaning "a cloud." Nephelite alters easily to natrolite, sodalite, cancrinite, kaolin or muscovite. It occurs as a pseudomorph after leucite.

(L. S. RL.)

NEPHELITE-SYENITE or ELEOLITE-SYENITE, a medium- to coarse-grained rock consisting largely of feldspar and nephelite; always considerably poorer in silica and richer in alkalies than granite. Nephelite-syenite from Canada is used in the place of feldspar in ceramic and glass products (*see* NEPHELITE).

Composition.—The feldspar in nephelite-syenite may be cryptoperthite (*see* FELDSPAR: *Unmixing at Low Temperature*) or a mixture of albite and microcline, the latter combination being on the whole rather rare. The place of nephelite is sometimes wholly or partly taken by sodalite or cancrinite. Quartz and calcic plagioclase feldspar are absent. The amount of dark silicates is generally somewhat greater than in granite, but rarely exceeds 30% by volume. The content of nephelite is also usually less than 30%; perhaps it would be more correct to say that rocks containing more than 30% either of dark silicates or of nephelite usually are not called nephelite-syenite.

The commonest dark silicate is green pyroxene, usually zoned from diopside cores to aegirine mantles. Alkaline amphibole (green, brown or blue) is also abundant, and in some areas pyroxene is virtually absent, its place being taken by a mixture of hornblende and biotite.

The accessory minerals include most of those found in granite, as well as a host of uncommon species, such as melanite, scapolite, pectolite, enigmatite, eudialyte, eucolite, mosandrite, lamprophyllite, perovskite, vesuvianite. Calcite is almost never absent and may be abundant. Minerals rich in zirconium, titanium and rare earths occur frequently and sometimes in great abundance. The extraordinarily varied mineralogy of the nephelite-syenites and their remarkable variation in habit, fabric, appearance and modal composition have attracted much attention; more petrographic research has been devoted to them than to any other plutonic rock.

Occurrence.—The amount of nephelite-syenite and related volcanic or plutonic rocks in the lithosphere is proportionately very small; the known or reasonably inferred volume of these rocks is probably less, for instance, than the volume of a single large gabbro complex. Yet they occur in great variety on every major land mass, and volcanic representatives are known from a considerable number of oceanic islands. Plutonic nephelite rocks ordinarily occur in small complexes, some quite isolated, but most in close association with effusive rocks of similar composition. The largest known masses are those on the Kola peninsula (U.S.S.R.), in Pilansberg (western Transvaal, S.Af.) and near Julianehaab (Ilimausak-Igaliko, Greenland). It is estimated that nephelite rocks underlie about 750 sq.mi. in Kola, about 200 sq.mi. in Pilansberg and about 100 sq.mi. near Julianehaab. No other dominantly plutonic complexes of comparable size are known, and most, including some of the most closely studied, are very much smaller.

Mode of Origin.—The magmas which give rise to nephelite rocks must in some way be derivative, either from other, more abundant magmas, or from reaction between one (or more) of these magmas and previously solidified rocks. Lime-rich accessory minerals abound in nephelite-syenite, and many nephelite-syenites are closely associated with limestone. Desilication of basaltic magma by assimilation of limestone was long ago proposed, and has been found to occur. It is extremely limited, however, and where nephelite rocks are genetically associated with other magmatic rocks, the latter are much more often granitic than basaltic. A granite-limestone syntexis, that is, chemical modification by fusion and incorporation of rocks in contact (*see* METASOMATISM), is accordingly favoured by some petrographers, and the field evidence for it is sometimes persuasive. Limestone, how-

ever, is a common sediment and is often intruded by granite, the commonest of all plutonic rocks. Why should the products of a reaction between the two be so rare?

The strongest alternative to syntectic explanations is the ingenious pseudoleucite hypothesis of N. L. Bowen, a generalization based on the observed or reasonably imagined consequences of the incongruent melting of orthoclase (*see* GEOCHEMISTRY: *The Reaction Series*). It is sometimes argued that the hypothesis requires an extraordinarily delicate co-ordination between crystallization and fractionation, but in view of the scarcity of undersaturated rocks this is not a critical objection. Far more important is the unconformable circumstance that leucite is not known to occur in plutonic rocks. One must thus assume either that the transformation of leucite to a mixture of nephelite and orthoclase always proceeds to completion at depth or that nephelite-syenites form in some other fashion.

In sum, despite the great interest that attaches to the nephelite-syenites and the immense amount of work that has been done upon them, there is little agreement about the way(s) in which these rare rocks have been formed.

NEPHROSIS: *see* URINARY SYSTEM: *Diseases and Their Medical Treatment.*

NEPHTHYS, Greek form of the name of the Egyptian goddess Nebtho. She seems to have been artificially created in apposition to Isis to be a second sister to the god Osiris and wife to his brother Set (Setekh). She plays practically no part outside the myth of Osiris, in which her only function is to bewail with Isis the death of Osiris. The meaning of her name ("Mistress of the Castle") suggests that she is a mere personification of Osiris' residence, while Isis (Egyptian Ese, "Seat") personifies his throne. (J. CY.)

NEPOS, CORNELIUS (b. probably between 100 and 90 B.C., d. probably shortly after 31 B.C.), Roman historian, correspondent of Cicero, biographer of Atticus (also a friend of Cicero), and the friend to whom Catullus dedicated his poems. He came, like Catullus, from north Italy. His principal writings were *De Viris Illustribus*, brief biographies of distinguished Romans and foreigners; *Chronica*, introducing to the Roman reader a Greek invention, universal comparative chronology; *Exempla*, anecdotes, perhaps a model for the biographer Valerius Maximus; possibly a universal geography to match the *Chronica;* and lives of the elder Cato and Cicero. There survive one book from the *De Viris Illustribus* (containing the following lives: Miltiades, Themistocles, Aristides, Pausanias, Cimon, Lysander, Alcibiades, Thrasybulus, Conon, Dion, Iphicrates, Chabrias, Timotheus, Datames, Epaminondas, Pelopidas, Agesilaus, Eumenes of Cardia, Phocion, Timoleon, certain kings, Hamilcar and Hannibal) and part of another book from the same work (containing lives of the younger Cato and Atticus). These lives are mostly very brief, being a few characteristic anecdotes uncritically strung together to illustrate trite moral principles; that of Atticus is longer, but absurdly eulogistic. Nepos is not notable as a literary stylist; he writes simply, but without elegance or purity.

NEPOS, JULIUS, Western Roman emperor 474–480, born of a distinguished family, was sent by Leo I to govern Italy as patrician. He at once took Glycerius (*q.v.*) prisoner and deposed him, and was himself proclaimed emperor in June 474. In 475 he was obliged to recognize the independence of the Visigothic kingdom centred on Toulouse. But the patrician Orestes, father of Romulus Augustulus, rose against him, and Nepos fled from Italy to Dalmatia in Aug. 475. He lived at Salona (modern Split in Yugoslavia) for five years, recognized in Gaul and in the east as emperor, though Romulus had usurped his position in Italy. He was eventually murdered by dependents of Glycerius on May 9, 480. (E. A. T.)

NEPTUNE (Latin NEPTUNUS; Etruscan NETHUNS), an Italian god of fresh water and hence not originally a sea-god. In cult he had a female counterpart, Salacia, who was perhaps a goddess of leaping spring water. He is early (at least by 399 B.C.) identified with the Greek Poseidon (*q.v.*) and hence becomes a deity of the sea. Subsequently his cult partner, in literature at least, was equated with the Greek Amphitrite.

Neptune's festival (Neptunalia) is listed in the oldest calendars and took place in the heat of the summer (July 23) when water was most wanting. Thus it may be conjectured that its purpose was the propitiation of the fresh-water deity. About the festival little is known save that the intense heat of the season necessitated the construction of shelters from the leaves of trees to keep the sun off the worshipers.

Neptune had a temple in the Circus Flaminius at Rome which was either built or extensively restored by Gnaeus Domitius Ahenobarbus, who was consul in 32 B.C. A coin of Domitius shows it to have been a tetrastyle temple. One of the features of the temple was a sculptured group of marine deities headed by Poseidon and Thetis, executed by Scopas and probably obtained by Domitius in Bithynia.

In art Neptune appears as the Greek Poseidon, whose attributes are the trident and the dolphin.

See W. W. Fowler, *Roman Festivals of the Period of the Republic* (1899); G. Wissowa, *Religion und Kultus der Römer* (1912); Platner-Ashby, *Topographical Dictionary,* s.v. (R. B. LO.)

NEPTUNE, astronomical symbol the trident ♆, is the eighth planet in order of increasing distance from the sun. The mean distance of Neptune from the sun is 2,796,700,000 mi. or 30.07 times that of the earth. Its period of revolution around the sun is 164.8 years.

Neptune receives so little light from the sun and is so far from the earth that it is invisible to the unaided eye. However, it is easily visible in a small telescope as a star of about the eighth magnitude. In a large telescope under favourable observing conditions the planet shows a greenish disk 2.5 seconds of arc in diameter. No surface markings have ever been detected upon the disk. From spectrographic observations the period of rotation was found to be 15.8 hours. The direction of rotation is the same as that of the earth.

The mass of Neptune, accurately known from the motion of its larger satellite, is 17.2 times that of the earth. The diameter of the planet is 27,600 mi. (44,516 km.), according to measurements made by G. P. Kuiper in 1949. This makes the mean density of Neptune 2.47 times that of water or 0.45 times the density of the earth. The albedo of Neptune, or ratio of the light reflected from the planet to that falling on it, is 0.62, indicating a cloud-covered surface of high reflecting power.

Although Neptune shines by light reflected from the sun, the greenish hue of the disk is due to the absorption of the red, orange and yellow solar rays by the planet's atmosphere. In the infrared region the absorption bands are so strong as nearly to obliterate the spectrum. The origin of the bands remained unknown until 1932 when R. Wildt identified them with methane (CH_4). The amount of methane in the atmosphere has been found to correspond to a thickness of 25 mi. of the gas under normal atmospheric pressure. The most abundant gases present are believed to be hydrogen and helium, derived originally from the sun and retained by the high velocity of escape from the planet's atmosphere. Unfortunately hydrogen and helium give no observable absorption markings in the spectrum so that their presence can only be inferred. There is a group of bands at λ 7500 found by Kuiper in 1949 in the spectra of Uranus and Neptune which has not been identified.

The temperature at the visible surface of Neptune is low, about −337° F. (−205° C.).

The Satellites of Neptune.—Neptune has two known satellites. The larger was discovered on Oct. 10, 1846 by William Lassell, only 17 days after the discovery of the planet itself. The

name of Triton was suggested for the moon by N. C. Flammarion and is often used. Triton revolves around Neptune at a mean distance of 220,000 mi. in a period of 5.876833 days. The direction of revolution is retrograde or opposite to the direction that Neptune rotates on its axis. The mass of Triton found by H. L. Alden (1943) is 0.022 times the mass of the earth or 1.8 times the mass of the earth's moon, in good agreement with earlier determinations. Its diameter has been estimated at 3,000 mi.

From the motion of the plane of the satellite's orbit and the period of Neptune's rotation, the oblateness, or deviation from spherical form, of the planet and the nature of its internal constitution can be inferred. From such deductions it is concluded that internally Neptune closely resembles Jupiter.

In 1948 a second satellite was discovered by Kuiper, who gave it the name of Nereid. According to G. Van Biesbroeck (1951), Nereid revolves around Neptune in the same direction the planet rotates in a period of 359.4 days. The mean distance or length of the semimajor axis of the satellite's orbit is 3,465,000 mi. But the eccentricity of the orbit is so high (0.76), that Nereid may approach as close as 832,000 mi. to Neptune, and recede as far as 6,100,000 mi. Kuiper estimated that Nereid is 180 mi. in diameter and 1/4,000 as massive as Triton.

The Discovery of Neptune.—By far the most interesting thing about Neptune is the story of its discovery. The account which follows was written by Simon Newcomb.

The detection of Neptune through its action upon Uranus before its existence had been made known by observation is a striking example of the precision reached by the theory of the celestial motions. So many agencies were concerned in the final discovery that the whole forms one of the most interesting chapters in the history of astronomy.

The planet Uranus, before its actual discovery by Sir William Herschel in the year 1781, had been observed as a fixed star on at least 17 other occasions, beginning with John Flamsteed in 1690. In 1820 Alexis Bouvard of Paris constructed tables of the motion of Jupiter, Saturn and Uranus, based upon a discussion of observations up to that year. Using the mutual perturbations of these planets as developed by Pierre Laplace in the *Mécanique céléste*, he was enabled satisfactorily to represent the observed positions of Jupiter and Saturn; but the case was entirely different with Uranus. It was found impossible to represent all the observations within admissible limits of error, the outstanding differences between theory and observation exceeding 1′. In these circumstances one of two courses had to be adopted; either to obtain the best general representation of all the observations, which would result in the tables being certainly erroneous, or to reject the older observations which might be affected with errors, and base the tables only on those made since the discovery by Herschel. A few years of observation showed that Uranus was deviating from the new tables to an extent greater than could be attributed to legitimate errors of theory of observation, and the question of the cause thus became of growing interest. Among the investigators of the question was F. W. Bessel, who tried to reconcile the difficulty by an increase of the mass of Saturn, but found that he could do so only by assigning a mass not otherwise admissible. Although the idea that the deviations were probably due to the action of an ultra-Uranian planet was entertained by Bouvard, Bessel and doubtless others, it would seem that the first clear statement of a conviction that such was the case, and that it was advisable to reach some conclusion as to the position of the disturbing body, was expressed by the Rev. T. J. Hussey, an English amateur astronomer. In a letter to Sir George B. Airy in 1834 he asked Airy's views of the subject, and offered to search for the planet with his own equatorial if the required estimate of its position could be supplied. Airy expressed himself as not fully satisfied that the deviation might not arise from errors in the perturbations. He therefore was not certain of any extraneous action; but even if there were such action, he doubted the possibility of determining the place of a planet which might produce it. In 1837 Bouvard, in conjunction with his nephew Eugène, was again working on the problem; but they appear not to have done more than to collect observations and to compare the results with Bouvard's tables.

In 1835 F. B. G. Nicolai, director of the observatory at Mannheim, Ger., in discussing the motion of Halley's comet, considered the possibility that it was acted upon by an ultra-Uranian planet, the existence of which was made probable by the disagreement between the older and more recent observations.

In 1838 Airy showed in a letter to the *Astronomische Nachrichten* that not only the heliocentric longitude but the tabulated radius vector of Uranus was largely in error, but made no suggestions as to the cause. In 1843 the Royal Society of Sciences of Göttingen, Ger., offered a prize of 50 ducats for a satisfactory working up of the whole theory of the motions of Uranus, assigning Sept. 1846 as the time within which competing papers should be presented. It is also recorded that Bessel, during a visit to England in 1842, in a conversation with Sir John Herschel, expressed the conviction that Uranus was disturbed by an unknown planet. He went so far as to set his assistant Fleming at the work of reducing the observations, but died before more was done.

The question had now reached a stage when it needed only a vigorous effort by an able mathematician to solve the problem. Such a man was found in John Couch Adams, then a student of St. John's college, Cambridge, who seriously attacked the problem in 1843, the year in which he took his bachelor's degree. He soon found that the observations of Uranus could be fairly well represented by the action of a planet moving in a radius of twice the mean distance of Uranus, which would closely correspond to Bode's law. During the two following years he investigated the possible eccentricity of the orbit, and in Sept. 1845 communicated his results to James Challis. About Nov. 1, 1845, Adams also sent his completed elements to Airy, stating that according to his calculations the observed irregularities in the motion of Uranus could be accounted for by the action of an exterior planet, of which the motions and orbital elements were given. It is worthy of note that the heliocentric longitude of the unknown body as derived from these elements is only between one and two degrees in error, while the planet was within half a degree of the ecliptic. Two or three evenings devoted to the search could not therefore have failed to make the planet known. Adams' paper was accompanied by a comparison of his theory with the observations of Uranus from 1780, showing an excellent agreement. Airy in replying to this letter inquired whether the assumed perturbation would also explain the error of the radius vector of Uranus, which he seemed to consider the crucial test of correctness.

The Elements.—At D. F. Arago's suggestion the investigation had been taken up by U. J. J. Leverrier, who had published some excellent work in theoretical astronomy. Leverrier's first published communication on the subject was made to the French Academy on Nov. 10, 1845, a few days after Adams' results were in the hands of Airy and Challis. A second memoir was presented by Leverrier on June 1, 1846. His investigation was more thorough than that of Adams. He first showed that the observations of Uranus could not be accounted for by the attraction of known bodies. Considering in succession various explanations, he found none admissible except that of a planet exterior to Uranus. Considering the distances to be double that of Uranus he then investigated the other elements of the orbit.

The following are the elements found by Adams and Leverrier:

	Leverrier	Adams	
		Hypothesis I	Hypothesis II
Semimajor axis	36.154	38.38	37.27
Eccentricity	0.1076	0.16103	0.12062
Long. of perihelion	284° 45′	315° 57′	299° 11′
Mean longitude	318° 47′	325° 8′	323° 2′
Epoch	1847, Jan. 1	1846, Oct. 1	1846, Oct. 1
True longitude	326° 32′	328°	329°

The longitude of the planet was 327° 57′ on Oct. 1, 1846.

The close agreement of these elements led Airy to suggest to Challis, on July 9, 1846, a search for the planet with the Northumberland telescope. He proposed an examination of a part of the heavens 30° long in the direction of the ecliptic and 10° broad,

and estimated the number of hours' work likely to be employed in this sweep. The proposed sweeps were commenced by Challis on July 29. The plan required each region to be swept through twice, and the positions of all the known stars found to be compared, in order that the position of the planet might be detected by its motion. On Aug. 31 Leverrier's concluding paper was presented to the French academy, and on Sept. 18 he wrote to John G. Galle (1812–1910), then chief assistant at the Berlin observatory, suggesting that he should search for the computed planet, with the hope of detecting it by its disk, which was probably more than 3″ in diameter. J. F. Encke, the director of the observatory, approved of the search, and with the aid of H. L. d'Arrest, a student, the search was commenced, but it was not found possible to detect any planet by its disk.

Star charts were at the time being prepared at the observatory under the auspices of the Berlin Academy of Sciences. It was suggested by d'Arrest that this region might be covered by one of the charts. It was found that such was the case. Comparing the stars on the chart one by one with the heavens it was found that an eighth-magnitude star now visible was not on the chart. On the following evening the object was again looked for, and found to have moved. The existence of the planet was thus established. It was afterward found that Challis had observed the planet on Aug. 4, but had failed to detect it.

In the debate whether Leverrier should receive the sole credit of the discovery, Arago argued that actual publication alone should be considered, rejecting Adams' communications to Airy and Challis as quite unworthy of consideration. He also suggested that the name of Leverrier should be given to the planet, but this proposal was received with so little favour outside of France that he withdrew it, proposing that of Neptune instead.

The observations at the first opposition showed that the planet was moving in a nearly circular orbit, and was at a mean distance from the sun much less than that set by Leverrier as the smallest possible. The latter had in fact committed the error of determining the limits by considering the variations of the elements one at a time, assuming in the case of each that while it varied the others remained constant. But a simultaneous variation of all the elements would have shown that the representation of the observations of Uranus would be improved by a simultaneous diminution of both the eccentricity and the mean distance, the orbit becoming more nearly circular and the planet being brought nearer to the sun. But this was not at first clearly seen, and Benjamin Peirce of Harvard university went so far as to maintain that there was a discontinuity between the solution of Adams and Leverrier and the solution offered by the planet itself, and that the coincidence in direction of the actual and computed planet was an accident. But this view was not well founded, and the only explanation needed was to be found in Leverrier's faulty method of determining the limits within which the planet must be situated. The actual motion of the planet during the century preceding, as derived from Leverrier's elements, was much nearer the truth than the elements themselves were. This arose from the fact that his very elliptic orbit brought the planet near to the sun, and therefore near to its true position, during the period from 1780 to 1845, when the action on Uranus was at its greatest.

The observations of the first opposition enabled Sears Cook Walker of the National observatory, Washington, D.C., in Feb. 1847 to compute the past positions of the planet, and identify it with a star observed by J. J. Lalande at Paris in May 1795. Lalande's manuscript showed that he had made two observations of the planet and finding them discordant had rejected one as probably in error and marked the other as questionable.

A mere re-examination of the region to see which observation was in error would have led him to the discovery of the planet more than half a century before it was actually recognized.

(S. N.; T. E. R. P.; S. B. N.; R. S. Rn.)

NEPTUNIUM, a synthetic chemical element, has the symbol Np and atomic number 93. In the periodic system of the elements it is the fourth member of the actinide series (*see* Periodic Law; Transuranium Elements). The long-lived isotope Np^{237} can be considered the parent of the missing $4n + 1$ radioactive series, and it has been suggested that this radioactive family be called the neptunium radioactive series by analogy with the names for the uranium and thorium radioactive series. The atomic weight of neptunium can be taken as that of its only long-lived isotope available in quantity, Np^{237}, whose atomic weight is 237.0480.

Discovery.—Among the many experiments stimulated by news of the discovery of atomic fission in uranium was a very simple one designed by E. M. McMillan at the University of California at Berkeley in 1940, with the object of testing the penetrating power of fission fragments. As a target at the cyclotron he used a piece of paper thinly coated with uranium oxide, backed by a stack of cigarette papers. After bombarding the uranium atoms with neutrons, he measured the radioactivity of each of the pieces of cigarette paper. He found in the uranium sample a radioactivity that evinced a different half-life and different properties from those of the fission products with which the other sheets were impregnated. He realized that this radioactivity might be caused by a previously undiscovered element. In the task of identifying the new substance, McMillan was joined by P. H. Abelson. They succeeded in chemically separating the first transuranium element, atomic number 93, which they named neptunium after the planet Neptune, the first planet beyond Uranus (after which the element uranium had been named). The neptunium isotope found by McMillan and Abelson has the mass number 239 and undergoes a 50% disintegration by radioactivity in 2.33 days (its half-life). The element was first isolated (using the long-lived isotope Np^{237}) in weighable quantity, as 10 μg. of the oxide, by L. B. Magnusson and T. J. LaChapelle in 1944 at the wartime Metallurgical Laboratory (now the Argonne National Laboratory) of the University of Chicago.

Occurrence and Production.—Traces of Np^{239} are to be expected in uranium minerals as a result of continual formation by capture in U^{238} of neutrons from various sources, according to G. T. Seaborg and M. L. Perlman. D. F. Peppard and co-workers established the presence of Np^{237} in Belgian Congo pitchblende in a concentration corresponding to a ratio of Np^{237} to U^{238} of 1.8×10^{-12}, the result of the action of fast neutrons.

In the late 1960s the only practical source of neptunium in weighable amounts was through the production of Np^{237} as a byproduct in nuclear chain reactors. In reactors utilizing U^{238} as fertile material, it results as the decay product of the short-lived, beta-particle-active U^{237}, which is formed by the action of neutrons on U^{238}. In such reactors fueled with natural uranium Np^{237} is produced at a rate of about 0.1% of that of the concur-

Table I.—*Isotopes of Neptunium*

Isotope*	Half-life	Type† and energy of radiation (Mev)
Np^{231}	~50 min.	α6.28

†EC = electron capture; α = alpha particle;
β^{-} = negative beta particle; β^{+} = positive beta particle.

rent Pu^{239} production. In high neutron flux reactors with enriched U^{235} as fuel, Np^{237} results from the successive absorption by U^{235} of two neutrons to form U^{236} and then U^{237}, which decays to form Np^{237}. The neptunium can be isolated by carrying on appropriate precipitates, by solvent extraction procedures, or by ion-exchange methods. The future may see the production of ton quantities of Np^{237} for use in the preparation of the useful isotope Pu^{238} (*see* PLUTONIUM).

Chemical Properties.—Metallic neptunium is highly electropositive, much like uranium and other actinide metals; it can be prepared by reducing the trifluoride or tetrafluoride with an active metal such as calcium or barium. The metal has a silvery appearance and melts at 640 ± 1° C. The room-temperature form of neptunium metal (α-neptunium) is orthorhombic (calculated density = 20.45 ± 0.03 g. per cubic centimetre). This form has been found to be stable up to 278° C, where it transforms into a tetragonal form (β-neptunium) with a density at 313° C of 19.36 g. per cubic centimetre. Above 570° C the metal seems to be cubic body-centred (γ-neptunium), and its density at 600° C is 18.0 g. per cubic centimetre. This phase is presumably stable up to the melting point. The metal is about as malleable as uranium made under the same conditions. Although the metal is chemically reactive, in common with other metals of the actinide elements, it does not tarnish rapidly when exposed to air at room temperature.

Using the isotope Np^{237}, it has been possible to establish the oxidation states and the properties of a large number of the compounds of neptunium. These investigations have shown that neptunium has the oxidation states VI, V, IV, and III with a general shift in stability toward the lower oxidation states as compared to uranium. The compounds which are formed are very similar to the corresponding compounds of uranium.

The ionic species corresponding to the oxidation states vary with the acidity of the solution; in acid solution and of moderate strength the species are Np^{3+}, Np^{4+}, NpO_2^+, and NpO_2^{2+}, similar to the ions of uranium and plutonium. The potential scheme (units of volts relative to hydrogen-hydrogen ion couple as zero) in one molar perchloric acid is as follows:

$$Np^0 \xrightarrow{+1.83} Np^{3+} \xrightarrow{-0.155} Np^{4+} \xrightarrow{-0.739} NpO_2^+ \xrightarrow{-1.137} NpO_2^{2+}$$

$$Np^{3+} \xrightarrow{-0.677} NpO_2^{2+} \qquad Np^{3+} \xrightarrow{-0.447} NpO_2^{+} \qquad Np^{4+} \xrightarrow{-0.938} NpO_2^{2+}$$

The metal is highly electropositive, in common with the other actinide elements. The $Np^{3+} \rightarrow Np^{4+}$ couple is reversible and this oxidation can be accomplished by the oxygen of the air. The IV state is stable, not oxidized by air, and only slowly oxidized to NpO_2^+ by nitric acid. The $Np^{4+} \rightarrow NpO_2^+$ couple is not readily reversible while the $NpO_2^+ \rightarrow NpO_2^{2+}$ couple is reversible; this is reasonable on the basis that the former involves breaking the neptunium-oxygen bonds while the latter does not. The oxidation of NpO_2^+ to NpO_2^{2+} requires moderately strong oxidizing agents.

Neptunium ions in aqueous solution possess characteristic colours: pale purple for Np^{3+}, pale yellow-green for Np^{4+}, green-blue for NpO_2^+, while NpO_2^{2+} varies from colourless to pink or yellow-green depending on the acid present. The sharp absorption bands are useful for quantitative and qualitative analysis for neptunium with the following the most useful: 5520, 6020, 6610, and 7875 Å for Np^{3+}; 5040, 7430, and 8250 Å for Np^{4+}; 4280 and 6170 Å for NpO_2^+; and 4760 and 5570 Å for NpO_2^{2+}.

The neptunium V ion NpO_2^+ is in many respects a unique ion, there being few if any elements forming a stable 5^+ oxidation state in solution that at the same time form a simple unpolymerized ion. The NpO_2^+ ion resembles other singly-charged cations such as K^+ in many respects. NpO_2^+, however, is complexed by oxalate ion in aqueous solution; this appeared to be the only complex ion of this oxidation state known in the late 1960s. In addition to the well-characterized neptunium V oxalate, a solid incompletely characterized potassium neptunium V carbonate is also known. The neptunium VI ion, NpO_2^{2+}, separates as the beautifully crystalline salt, $NaNpO_2(CH_3COO)_3$, sodium neptunylacetate, from solutions containing high concentrations of sodium ions and acetate ions.

TABLE II.—*The Halides of Neptunium*

Compound	Colour	Crystal structure	Density* (g./cc.)	Melting point (° C)	Boiling point (° C)
NpF_3	purple	hexagonal	9.12	—	2500†
NpF_4	light green	monoclinic	6.8	—	1750†
NpF_6	white(?)	orthorhombic	—	53	decomposes
$NpCl_3$	white	hexagonal	5.58	800†	1800†
$NpCl_4$	red brown	tetragonal	4.92	—	—
$NpBr_3$	green	hexagonal	7.11	—	1800†
$NpBr_4$	red brown	UBr_4 type	—	740	decomposes(?)
NpI_3	brown(?)	orthorhombic	6.82	—	—

*Calculated from X-ray diffraction data.
†Estimated values.

The neptunium-oxide system exhibits complexity similar to but perhaps less than that found in the uranium-oxide system. Thus the important oxide is NpO_2 and there exists a range of compositions, depending upon the conditions, up to Np_3O_8. The oxide of composition NpO_3 has also been prepared. The important halides of neptunium are summarized in the accompanying table.

NERBUDDA: *see* NARMADA.

NEREIDS, in Greek mythology the daughters (numbering 50 or 100) of a sea-god, Nereus (eldest son of Pontus, a personification of the sea, and Gaea, the earth goddess), and of Doris, daughter of Oceanus. They were imagined as young girls, inhabiting any water, salt or fresh, and as benign toward mankind. They were not worshiped as much as some nymphs, but were popular and literary figures. The best known of the Nereids are Amphitrite, consort of Poseidon; Thetis, wife of Peleus and mother of Achilles; and Galatea, a Sicilian figure loved by the Cyclops Polyphemus.

See also NYMPH. (H. W. PA.)

NERETVA, a river of Yugoslavia in Hercegovina and Dalmatia, rises in the Cemerno Mountains and flows for 135 mi. in a northwesterly direction past Konjic through Jablanica Lake and then southwest via Mostar and Gabela (its head of navigation) to the Adriatic Sea. Much of the course of the river is flanked by cliffs. With the building of the Jablanica Dam, Neretva formed an artificial lake of crystal green-blue waters, abounding in fish and provided water for an important hydroelectric station. During World War II Yugoslav partisans fought one of the most decisive battles against the Germans and Italians in the Neretva gorges. (V. DE.)

NERGAL, a secondary god of the Sumero-Akkadian pantheon. He was identified with IRRA, the god of pestilence, and with MESLAMTAEA, "he who comes forth from Meslam" (*i.e.*, from Hades). A text of King Shulgi of the 3rd dynasty of Ur (*c.* 2000 B.C.) gives the name Emeslam to Nergal's temple at Cuthah (modern Tell Ibrahim), the chief centre of his cult. A text saying that "Shamash and Nergal are one" may indicate that Nergal was originally a solar deity. In later thought he also was "a destroying flame" and has the epithet "burner," *sharrapu*.

His name is Sumerian, meaning "Lord of the Great Abode." It does not occur on the earliest Sumerian texts nor on Semitic texts of the dynasty of Akkad (*c.* 24th century B.C.). A later tradition makes King Naramsin of that dynasty attribute to Nergal his victories. The few references to Nergal on texts of the 3rd dynasty of Ur reveal nothing of his nature or genealogy. A little later Kudurmabuk, king of Larsa, describes him as "the first in rank of the sons of the god Enlil," "full of mighty force and terrifying splendour." Kudurmabuk's son Rim-Sin adds that Nergal causes not only fear and death but also life and vegeta-

tion. Hammurabi (*c.* 18th century B.C.) beseeches him, as "the fighter without a rival who brought him victory," to destroy any who contemn his laws. Assyrian documents of the 1st millennium B.C. describe him as a benefactor of men, who hears prayers, restores the dead to life and protects agriculture and flocks. Hymns depict Nergal as a god of pestilence, hunger and devastation. The names of the 14 demons who accompany him are, for the most part, names of diseases. He works destruction, especially at night.

The other sphere of Nergal's power is the underworld, of which he became "king" and "great in Arallu." From the two fragments of an Akkadian text found at Tell el Amarna it appears that Nergal, escorted by demons, descends to the underworld where the goddess Ereshkigal (*q.v.*) is queen. He threatens to cut off her head. She saves herself by becoming his wife, and Nergal obtains "kingship over the wide underworld" and the "tablets of wisdom" (probably the tablets on which were written the names of persons whose date of death had been decided).

Nergal does not figure prominently in epics and myths. In the Epic of Gilgamesh, however, it is he who opens a hole in the ground from which the spirit of Enkidu, the dead friend of Gilgamesh, comes forth. In the deluge story, "Irragal" (*i.e.*, Nergal) takes a hand in bringing devastation to the earth by tearing out its posts.

The cult of Nergal was very widespread beyond the borders of Sumer-Akkad, where it first appears. He had a sanctuary at Mari (modern Tell el Hariri), on the Euphrates. Inscriptions of Assyrian kings name him. To Sargon II (722–705 B.C.) he is one of the "gods who dwell in Kalakh" (modern Nimrud). There was a gate of Nergal at Nineveh by Sargon's son Sennacherib and a temple to him at Tarbisi, to the north (by Sennacherib and Ashurbanipal). Inhabitants of Cuthah, transported to Samaria, brought their god with them (II Kings xvii, 24–31). The name of "Atanahili, slave of Nergal," occurs on a Babylonian cylinder found at Taanach in Canaan. There were priests of Nergal at Piraeus, the port of Athens. A letter found on the island of Elephantine in the Nile includes Nergal in a list of gods. *See* also BABYLONIA AND ASSYRIA: *Religion: Sumerian Pantheon.*

NERI, SAINT PHILIP (FILIPPO NERI) (1515–1595), one of the outstanding figures of the Counter-Reformation, known as the second "apostle of Rome," was the founder of the Institute of the Oratory (*see* ORATORIANS). St. Ignatius of Loyola and St. Charles Borromeo were his friends, the church historian Caesar Baronius was his disciple, and Palestrina came within his circle. Born in Florence on July 21, 1515, Philip left the city at about the age of 18 for the home of a relative near Monte Cassino. After what might be termed a conversion (though his life was innocent), he went to Rome where he spent his remaining 60 years. He tutored the sons of a Florentine in return for an attic and a pittance. He attended lectures on philosophy and theology, though not intending to receive holy orders but rather to pursue a lay apostolate. Cheerful and open by temperament, he conversed with the young men of the city in order to lead to some serious question: "Well, and when shall we begin to do good?" He served in the hospitals and frequently spent whole nights in prayer in the catacombs of St. Sebastian.

In 1548 he founded the confraternity of the Holy Trinity to give hospitality to poor pilgrims and convalescents discharged from hospitals.

In 1551, prevailed on by his spiritual adviser, he was ordained priest and went to reside with the chaplains at San Girolamo della Carità, in the via di Monserrato. There he gathered in his room the young men he had already grouped around him and others whom he won by an assiduous ministry in the confessional. These meetings had some resemblance to modern discussion groups with the addition of prayers and hymns. When numbers increased he transferred these meetings to the church attics. They called this locality "the Oratory," a name that came to be applied also to those who met there and to the devotional, charitable and recreational activities that Philip devised for them (among these music, whence ultimately "oratorio"). For a time (1564–75) Philip was rector of the Florentines' church of San Giovanni; in this period Baronius and other disciples were ordained, thus forming the germ of a new community.

In 1575, a bull of Gregory XIII granted Philip the ancient church of Sta. Maria in Vallicella and established there in perpetuity "a Congregation of secular priests and clerics known as the Oratory." The old church was pulled down and a new one built—still called the Chiesa Nuova—and a house for the priests, though it was not until 1583 that Philip went there to reside. In 1577 he was formally elected provost of the congregation.

Apart from the pressure he exerted on Pope Clement VIII to obtain the absolution from excommunication of King Henry IV of France, Philip played no part in the political events of the time. His work was essentially one of personal influence; he attracted men not merely by his joyfulness and humour but, even more, by the spiritual gifts he manifested. His fervour of spirit was accompanied by a sensation of physical heat and a violent palpitation of the heart; distrustful of all ecstatics he was frequently carried away by ecstasies himself. Many miracles were attributed to him, notably the raising to life of Paolo dei Massimi. Up until the end of his life he continued to hear confessions and receive all who sought his help.

Philip died on May 26, 1595, and was buried in the church he had built. He was canonized in 1622; his feast day is May 26.

NERNST, WALTHER HERMANN (1864–1941), German chemist, winner of the 1920 Nobel prize in chemistry for his thermochemical work, was one of the founders of modern physical chemistry, making fundamental contributions in the fields of electrochemistry, theory of solutions, thermodynamics, the solid state and photochemistry. He was born June 25, 1864, in Briesen, West Prussia, and was educated at the universities of Zürich, Graz and Wurzburg. In 1887 he became assistant to Wilhelm Ostwald (*q.v.*) at Leipzig university. Ostwald, along with J. van't Hoff and Svante Arrhenius, was then establishing physical chemistry as an independent branch of chemistry, and Nernst, in the midst of such a stimulating group, at once began his own important researches.

His academic career commenced with his appointment to the physics department of the University of Göttingen in 1890. In 1905 he moved to the Physicochemical laboratory of the University of Berlin and in 1924 he became director of the Institute for Experimental Physics there. He remained in this position until his retirement in 1933. His electrochemical studies were begun under the inspiration of the then new dissociation theory of Arrhenius which first recognized the importance of ions in solution.

In 1889 Nernst worked out the theory of galvanic cells by assuming a solution pressure which forced ions from the electrode into solution and which was opposed by an osmotic pressure of the dissolved ions. In the same year, still thinking in terms of ions, Nernst derived the equations for the solubility product which defined the conditions under which solids precipitate from saturated solutions. In 1906 he announced his heat theorem, or third law of thermodynamics, which showed that the maximum work obtainable from a process could be calculated from the heat evolved at temperatures near absolute zero. This made precise the older ideas which had neglected the effects of temperature and permitted calculation of conditions of equilibrium in many chemical reactions. Besides its great theoretical importance, the theorem had many industrial applications, including calculations for the synthesis of ammonia. Nernst received the Nobel prize for his formulation of the heat theorem. Nernst and his students made many important physicochemical measurements, especially the determination of vapour densities at high temperatures and of the

specific heats of solids at very low temperatures. These he considered from the point of view of the quantum theory. In 1918 his photochemical studies led him to the atom chain reaction theory. This assumed that once the energy of a quantum has initiated a reaction in which free atoms are formed, these atoms can in turn decompose other molecules with the liberation of more free atoms, and so the reaction can continue for long periods without further illumination. This mechanism explained many reactions which had puzzled photochemists.

Nernst was mechanically minded and was much interested in the application of science to industry. Besides his theoretical contributions he invented an improved electric light and a piano with electronic amplification of its sounds. His inventions never received wide acceptance, however. His textbook on theoretical chemistry, first published in 1893, was influential for many years. He also published a number of monographs in his special fields. In his later years he concerned himself chiefly with astrophysical theories, a field in which the heat theorem also had important applications. He died Nov. 18, 1941, in Muskau. (H. M. L.)

NERO (NERO CLAUDIUS CAESAR) (A.D. 37–68), Roman emperor from A.D. 54 to 68, born on Dec. 15, 37, was an Ahenobarbus (*q.v.*) by birth, his original name being Lucius Domitius Ahenobarbus. His father died about 40, and his mother, Agrippina (*q.v.*) the younger, a great-granddaughter of Augustus, became in 49, on Messallina's death, the wife of her uncle, the emperor Claudius I. Claudius' son Britannicus was only three years younger than Nero; but Agrippina persuaded Claudius in 50 to adopt Nero and later to give Nero his daughter Octavia in marriage and mark him out for the succession by various honours. On Oct. 13, 54, Claudius died, poisoned, it was said, by Agrippina; she at once had her son proclaimed by the praetorian guard, whose prefect Burrus (*q.v.*) was her partisan; the senate had to accept a *fait accompli*. For the first time absolute power in the empire was vested in a mere boy, not yet 17.

Agrippina immediately eliminated the powerful freedman Narcissus, who had always opposed her aims, and Marcus Junius Silanus, a descendant of Augustus and a potential pretender. She hoped to control the government, and in 55 her dominance is symbolized in coins which bear her name and bust. But Burrus and Nero's old tutor, the philosopher Seneca (*q.v.*), though they owed their influence to her, were not content to remain her tools. They encouraged Nero in an amour with the freedwoman Acte, of which Agrippina disapproved; this led to a growing coolness in her relations with Nero. She even showed favour to Britannicus, and Nero retaliated by poisoning him. In 56 she was forced into retirement. From that time, if not earlier, till 62 Burrus and Seneca were the effective rulers of the empire.

On his accession Nero had promised in a speech written by Seneca to put an end to the most odious features of the Claudian regime, secret trials before the emperor and dominance of corrupt freedmen, and to accord more independence to the senate. For some time these promises were largely fulfilled. Secret trials were few. Narcissus was dead; his rival, the financial secretary Pallas, retired in 55. Not till 66, when Nero left Helius in charge of Italy, did any freedman openly enjoy such power as they had done. The senate had more liberty in debate. The law of treason was dormant; Claudius had put 40 senators to death, but between Marcus Silanus' murder and 62 there were no like incidents in Nero's reign.

The great question of the day was that of Armenia. Since Augustus it had been Roman policy to appoint vassal kings and so make it a buffer against Parthia. But the Armenians could rarely tolerate Roman nominees and the Parthians regarded Roman control of Armenia as a threat to their own security. In Claudius' last years a Parthian prince, Tiridates, had possessed himself of the country with the good will of most of its people. Claudius had done nothing; the new government took vigorous action, appointing an able general, Corbulo (*q.v.*), to the command. Prolonged and desultory operations led in 66 to a new settlement; Tiridates was recognized as king, but had to come to Rome to do homage to Nero. This settlement had probably been the consistent aim of Nero's government (*see* Tacitus, *Annals*, xiii, 9, 34, 37; xv, 5, 25), though Parthian intransigence forced it *c.* 59 to revert temporarily to the Augustan pattern. It is generally held that this arrangement, which most of Nero's successors adopted, made for more harmony with Parthia; yet with Armenia no longer dependent the Romans had to post two more legions on the Euphrates to guard against Parthian attacks. Whatever the merits of the new policy, they must be credited to Nero's early advisers, even though it was only in his last years that it could be put into effect.

While directing the government themselves, Burrus and Seneca left Nero to pursue his own tastes and pleasure uncontrolled. In his essay *De clementia*, Seneca urged him to use his autocratic power conscientiously, but he failed, if indeed he tried, to harness the boy's more generous impulses to his responsibilities. At first Nero hated signing death sentences, and the extortions of the tax-farmers led him to suggest in 58 that the customs dues should be abolished; this was of course impracticable and only abortive reforms resulted. Even later Nero was capable of grandiose plans —for rebuilding Rome, for cutting a canal through the Isthmus of Corinth, or for eastern conquest. But for the most part he used his position simply to gratify his own personal pleasures. As early as 56 his nocturnal rioting in the streets was a grave scandal. In 58 he became attached to the wife of Otho (*q.v.*), Poppaea Sabina. Agrippina objected and in 59 he had her murdered. Seneca himself was employed to justify her death as that of a traitor. No one believed this, but all accepted it. Nero concluded that he was free to behave as he chose. He fancied himself not only as a poet but as a charioteer and lyre player, and in 59–60 he began to give public performances; later he also appeared on the stage. To the Roman mind these were infamous breaches of decorum. Seneca felt that he had lost all influence and, after Burrus' death in 62, retired. Nero at once divorced Octavia on a trumped-up charge of adultery and soon put her to death; he then married Poppaea (62); she died in 65 and Nero subsequently married Statilia Messallina.

The great fire at Rome illustrates how low his reputation had sunk by 64. He did what he could to relieve the homeless and initiated rebuilding on a much better plan. Yet it was believed, without warrant, that he had fired the city himself in order to indulge his aesthetic tastes in its reconstruction. Nero tried to shift the charge on to the Christians, who were commonly thought to practise all kinds of wickedness. Hitherto the government had not clearly distinguished Christians from Jews; almost by accident, Nero initiated the later policy of intermittent and half-hearted persecution and earned himself the reputation of Antichrist in the Christian tradition.

Hated and therefore suspicious, Nero began in 62 to remove men whose lineage made them seem dangerous. In 65 a plot to make Gaius Calpurnius Piso emperor was quenched in a blood-bath; Lucan (*q.v.*) perished, as did Seneca, who may have been guiltless. It was ominous that the conspirators included military officers, one of whom spoke for all respectable people in denouncing Nero as "murderer of his mother and wife, a charioteer, an actor and an incendiary" (*Annals*, xv, 67). A reign of terror ensued among the high classes; among the victims was the upright Thrasea Paetus, who had retired from public life in protest against Nero's conduct (A.D. 66).

In 67 Nero went to Greece to display his artistic prowess. Perhaps while he was there, a new plot was revealed; its author was a son-in-law of Corbulo, and Nero thought it prudent to recall both Corbulo and the generals of the Rhine armies and order their death. But the situation remained so tense that Helius (*see* above) urgently recalled him to Rome.

The provinces too were oppressed. Misgovernment in Britain had provoked Boudicca's revolt in 60 (*see* BOADICEA), and in Palestine Jewish patience was exhausted in 66; the great insurrection lasted till 70. Exactions are most fully documented from Egypt, but the scanty allusions in extant literary sources suggest that if similar papyrological evidence survived from elsewhere it would tell much the same story. They resulted from Nero's extravagance in court expenditure, buildings and gifts to his favourites; the last are said to have amounted to 2,200,000,000 sesterces, a sum

probably over five times the annual cost of the army. At Nero's death the treasury was empty and the soldiers' pay had fallen into arrears. Nero had thus earned the hatred and contempt of the old ruling class at Rome; the Italian middle class, which had old-fashioned moral views and from which many or most army officers were drawn; the provincials; and even the troops.

In March 68 Julius Vindex, a Gallic senator who was governing Gallia Lugdunensis, raised a revolt; he had no army, but he could appeal not only to his oppressed fellow Gauls but also to Romans and provincials everywhere. Galba (*q.v.*), the governor of Nearer Spain, lent the revolt the authority of his high birth and reputation, and even the Rhine legions, though they destroyed Vindex at Besançon, threw off their allegiance. At Rome the praetorians followed suit; proscribed by the senate, Nero cut his throat on June 9. The Roman populace and later the praetorians regretted a liberal patron. To his subjects in general he had been a tyrant, and the revolt his misrule provoked sparked off a series of civil wars which threatened the survival of the empire and caused widespread misery. For portrait *see* article ROMAN HISTORY. *See* also references under "Nero" in the Index.

NERTHUS (HERTHA), in Germanic mythology, the goddess of fertility, "Mother Earth," stated by Tacitus to be worshiped with orgies and mysterious rites at night by Teutonic tribes. Her veiled statue was moved from place to place by sacred cows. After the rites the image, vestments and vehicle were bathed in a lake.

NERVA, MARCUS COCCEIUS (A.D. 30 [probably]–98), Roman emperor from Sept. 18, 96, to Jan. 27 or 28, 98, was a member of a distinguished senatorial family distantly related by marriage to the Julio-Claudian house. He had been twice consul (A.D. 71 and 90) when, on the assassination of Domitian, he was invited to be emperor by the conspirators and gladly accepted by the senate. A number of elder statesmen emerged from retirement to help him in the task of government, and the keynote of the regime was a skilfully propagandized return to public and private freedom after the tyranny of Domitian. Sound, though uninspired, measures were taken, concentrating on the welfare of Rome, Italy and the *cives Romani;* they included the last *lex populi* in Roman history, an agrarian law on the Gracchan model. The one imaginative innovation commonly attributed to Nerva's government, the system of *alimenta*, which combined a farming subsidy with the establishment of trusts for the maintenance of poor children in Italy, was more probably the work of Trajan.

In 97 the praetorian guard, instigated by one of its commanders, forced Nerva to hand over the men who had given him the principate, Domitian's murderers, to be murdered in their turn. His helplessness convinced him that he must secure the succession, and in the second half of 97 he adopted and took as colleague M. Ulpius Traianus, governor of one of the German provinces. Trajan had no need to return to Rome; the government went quietly on, and Nerva died in his bed in Jan. 98. He was the last emperor to be buried in the mausoleum of Augustus.

Nerva is usually described as benevolent but feeble; historians echo Pliny in saying that only by the adoption of Trajan was a total collapse of government prevented. Some believe that the choice of Trajan was forced upon Nerva by a "Spanish party" at court and in the army. This is an exaggerated view, not proved by the evidence. Nerva was old and childless; he had therefore to choose a successor sooner or later, and his death early in 98 shows that he chose none too soon. It does not follow that the choice was forced on him; he should be given the credit for statesmanlike rule and wisdom in deciding who was best fitted to succeed him.

NERVAL, GÉRARD DE (pseudonym of GÉRARD LABRUNIE) (1808–1855), French poet, whose talent, long undervalued as that of a minor writer, was rediscovered in the 20th century, when it was recognized that, especially in his last works, he had symbolized the aspirations of romanticism by his power to transmit the drama of his own inner life with brilliant intensity.

He was born in Paris on May 22, 1808, and, in the same year his father, a doctor, was sent to serve with Napoleon's Rhine army. His mother left him in the care of a nurse in the country, and joined her husband in Hanover. She died in 1810, and Gérard was placed in charge of a great-uncle at Mortefontaine in the Valois. The memory of his childhood there was to haunt him with its poignant sweetness all his life. In 1820 he went to live with his father in Paris, in order to attend the Collège Charlemagne, where he formed a lasting friendship with Théophile Gautier (*q.v.*), a fellow student. For a few years he led a carefree existence, shared with Gautier and other friends, in which dances and suppers counted more than the demands of literature. A legacy from his grandparents gave him the means to travel in Italy. These years, a time which Gérard later called his "*bohème galante*," reached their climax in 1835, when the young painters and poets used to meet in an old house in the Impasse du Doyenné. This lighthearted time soon ended, however. The *Monde dramatique*, a periodical into which Gérard had poured the remains of his legacy, failed. And in 1836 he fell passionately in love with Jenny Colon, an actress; two years later she married and in 1842 she died. This shattering experience changed his life. Later in the same year he was able to set out on his travels to Egypt and the Levant, and in the years that followed he both wrote and published; but from then on his life was ridden by such violent obsessions that his reason was constantly endangered and on eight occasions he had to be sent to mental hospitals for care. These years of anguish and destitution ended in the dawn of Jan. 26, 1855, when he was discovered hanging from a lamppost in the Rue de la Vieille-Lanterne, Paris.

Until 1836 Nerval's gifts as a writer were dissipated in work which failed to reflect his particular genius; neither the poems of patriotism, the stories in the manner of E. T. W. Hoffmann, the intimate verse, nor even the adaptation of Goethe's *Faust* would have been enough to ensure his fame. He began to write from his deepest self in the *Voyage en Orient* (1843–51). At the foot of the pyramids, in Syria and in Lebanon he pursues the phantom of his beloved or seeks analogies between his personal obsessions and oriental folktales. The goddess Iris appears to him as the image of the Eternal Feminine of which Jenny herself had been a fugitive incarnation.

Finally he wrote his masterpieces. "Sylvie," written in 1853 and included in *Les Filles du feu* (1854), is a short story in which the countryside where he had been happy as a child and the women he had loved are recreated in musical, lucid prose. His playmate Sylvie, with all her peasant simplicity, is a foil both to the high-born grace of Adrienne, glimpsed long ago in the gardens of a château, and to the magical enchantment of Aurélia who is none other than Jenny Colon herself. The memory of Jenny Colon also dominates *Aurélia* (1853–54), a longer story written during the intervals of his last mental crises: here he describes his obsessions and hallucinations, as well as his trust and hope, and in the final visions the image of Aurélia merges with that of the Virgin who assures him of salvation. Finally, *Les Chimères* (1854) is a sonnet sequence of extraordinary complexity in which the images derived from his reading coalesce with those that echo his personal life; a literal commentary is often difficult to achieve, but the splendid music of the language in the most perfect of the sonnets ("El Desdichado," "Artémis") has an overwhelming power. As a poet and writer of prose Gérard de Nerval attained the summit of his art whenever he combined his exquisite taste with his infallible intuition for the appropriate image to transcribe the dreams of his sensitive spirit, forever in quest of an unattainable paradise.

(P.-G. CA.)

NERVE, in anatomy, is a glistening white cordlike bundle of fibres, surrounded by a sheath, that connects the nervous system with other parts of the body (*see* NERVOUS SYSTEM). The nerves conduct impulses toward or away from the central nervous mechanism. In man 12 pairs, the cranial nerves, are attached to the brain and 31 pairs, as a rule, of spinal nerves attach to the spinal cord. The fibres constituting the individual nerves are very numerous, and all, save those arising in the sympathetic ganglia, extend from the brain or cord to the peripheral structures which they innervate.

With respect to function, nerve fibres are divided into two categories, namely, sensory or afferent and motor or efferent. The fibres of these categories and their subdivisions constitute the functional components of the nerves. The combinations of such components vary in the individual cranial nerves; in the spinal nerves they are more uniform.

The afferent (sensory) fibres are subdivided into somatic and visceral groups. The somatic afferents conduct impulses received from outside the body or produced by movements of the muscles and joints, those from the muscles and joints also being known as proprioceptive fibres. The visceral afferents conduct messages from the organs serving the internal economy of the body; such impulses result in reflex control of these organs (*e.g.*, the rate of the heart beat, activities of the digestive system and others).

The motor fibres also are divided into somatic and visceral motor or efferent groups. Somatic efferent fibres innervate voluntary muscles that derive from the myotomes of the embryo (*see* MUSCLE AND MUSCULAR SYSTEM). Visceral motor fibres are subdivided into special visceral efferents, which innervate striped muscles of branchial origin, and general visceral efferents, which innervate involuntary muscle and secreting glands. The general visceral efferent fibres constitute the autonomic system, of which there is a sympathetic division and a parasympathetic division, based on differences in anatomical arrangement and physiological characteristics. The term sympathetic also is frequently used to include both divisions as well as the ganglia and afferent fibres associated with them.

The autonomic pathway involves a chain of two fibres, one arising in the brain or spinal cord and ending in a sympathetic ganglion (hence called the preganglionic fibre), the second (the postganglionic fibre) arising in the ganglion and passing to the organ innervated.

CRANIAL NERVES

The cranial nerves (fig. 1[A]) are designated by name and also by number, Roman numerals being conventionally used as a rule. They emerge through openings (foramina) of the skull (*see* SKULL). Some of the cranial nerves are purely sensory, some entirely motor and others are mixed. The afferent fibres, save those of the olfactory and optic nerves, arise in the cranial sensory ganglia, situated in the course of sensory nerves near the brain. Central processes (in this context the word process means a projecting part, an extension) terminate in sensory nuclei of the brain. The motor fibres arise within the brain from motor nuclei. In some instances the central nuclei, sensory or motor, are distinct for each nerve; in others the functional components of the same category from several nerves may enter or arise from a nucleus shared in common.

In addition to the 12 pairs described below, a small pair, the nervus terminalis, whose significance is obscure, is found in close relation with the olfactory nerve.

Olfactory Nerve.—The first cranial nerve is entirely afferent, serving the sense of smell. It comprises about 20 small filaments formed by convergence of numerous fibres that arise from cells in the olfactory mucous membrane. These cells also are the olfactory receptors and are unique since, besides being percipient, they give rise to long nerve fibres. The filaments enter the brain cavity through small openings in the anterior part of its floor and terminate in the olfactory bulb of the forebrain (fig. 1[A]). (*See also* OLFACTORY SYSTEM.)

Optic Nerve.—The second cranial nerve serves the sense of sight and is entirely afferent. Its cells of origin lie in the retina of the eye. The nerve fibres emerge from the back of each eyeball

FIG. 2.—DIAGRAM OF THE OPTIC NERVE, OPTIC TRACT AND CENTRAL CONNECTIONS

as a bundle called the optic nerve. The two nerves converge and form the optic chiasma, from which the optic tract continues to the lateral geniculate body of the thalamus and the superior colliculus and pretectal area of the midbrain (fig. 1[A] and 2). The nerve fibres, however, pass without interruption from the retina to the centres named.

Those from the medial (toward the nose) half of each retina cross in the chiasma and enter the opposite optic tract; those from the lateral (toward the temples) side of the retina enter the optic tract of the same side. The optic centres of either half of the brain, accordingly, receive fibres from both eyes. (*See* also EYE, HUMAN.)

Oculomotor Nerve.—The third cranial nerve has its origin in the oculomotor nucleus of the midbrain (fig. 3). This nucleus comprises (1) a group of cells, the principal nucleus, which sends fibres to the extrinsic eye muscles; and (2) the nucleus of Edinger-Westphal, which gives rise to preganglionic parasympathetic fibres.

The nerve emerges from the underside of the midbrain and divides into a superior branch and an inferior branch. The superior branch supplies one of the muscles of the eyeball and the muscle of the upper eyelid. The inferior branch supplies three of the muscles of the eyeball; from the branch to one of these muscles the preganglionic parasympathetic fibres pass by a short connection to the ciliary ganglion. This ganglion gives rise to postganglionic fibres that enter the eyeball and end in the constrictor muscle of the iris and the ciliary muscle. The oculomotor nerve also includes proprioceptive fibres to the extrinsic eye muscles.

FIG. 3.—DIAGRAM OF ROOTS OF CRANIAL NERVES III TO XII, THEIR CENTRAL NUCLEI AND FUNCTIONAL COMPONENTS

Right side: Sensory components and nuclei; *left side:* motor components and nuclei. Cranial autonomic ganglia, situated at a distance from the brain, are indicated in connection with the appropriate nerve roots
Nerves: (N. III) oculomotor; (N. IV) trochlear; (N. V) trigeminal; (N. VI) abducens; (N. VII) facial; (N. VIII) acoustic, including cochlear and vestibular divisions; (N. IX) glossopharyngeal; (N. X) vagus; (N. XI) spinal accessory; (N. XII) hypoglossal
Nuclei and Ganglia: (1) nucleus of Edinger-Westphal; (2) ciliary ganglion; (3) oculomotor nucleus; (4) trochlear nucleus; (5) motor trigeminal nucleus; (6) abducens nucleus; (7) motor facial nucleus; (8) superior salivatory nucleus; (9) inferior salivatory nucleus; (10) vagus and glossopharyngeal dorsal motor nucleus; (11) spinal accessory nucleus; (12) hypoglossal nucleus; (13) nucleus ambiguus; (14) submaxillary and sphenopalatine ganglia; (15) otic ganglion; (16) vagus visceral ganglia; (17) mesencephalic trigeminal nucleus; (18) superior sensory trigeminal nucleus; (19) spinal trigeminal nucleus; (20) solitary tract nucleus; (21) vestibular nuclei; (22) cochlear nuclei; (23) semilunar ganglion; (24) geniculate ganglion; (25) spiral ganglion; (26) vestibular ganglion; (27) superior glossopharyngeal ganglion; (28) glossopharyngeal petrous ganglion; (29) vagus jugular ganglion; (30) vagus nodose ganglion; (31) direct vestibular fibres to cerebellum

Trochlear Nerve.—The fourth cranial nerve has its origin in the trochlear nucleus (fig. 1[A] and 3). The fibres cross to the opposite side and emerge dorsally, continuing as a long slender strand to the superior oblique muscle of the eyeball. Proprioceptive fibres probably are included with the predominant motor component.

Trigeminal Nerve.—The fifth cranial nerve (fig. 1[A] and 3) is the largest of this group. It has sensory and motor roots, both attached at the anterior lateral surface of the pons. The sensory fibres arise from the semilunar ganglion, their central processes terminating in the superior and spinal trigeminal nuclei. The peripheral fibres are gathered into three divisions, (1) the first or ophthalmic, (2) the second or maxillary and (3) the third or mandibular.

Ophthalmic Nerve.—This supplies a branch to the dura mater of the brain and then divides into lacrimal, nasociliary and frontal nerves, the last subdividing into supraorbital and supratrochlear branches. The latter two nerves supply the skin of the upper part of the face and the front of the scalp (fig. 4). The lacrimal nerve also sends twigs to the conjunctiva of the eye, and the supratrochlear nerve supplies part of the conjunctiva of the upper eyelid.

Maxillary Nerve.—Numerous branches are given off by the maxillary. These are (1) a small meningeal nerve; (2) two connections with the sphenopalatine ganglion that continue as pharyngeal, palatine and nasopalatine nerves to the mucous membrane of the pharynx, palate and nasal cavity; (3) the posterior superior alveolar nerve to the upper teeth; (4) the zygomatic nerve to the skin of the prominence of the cheek and the temple; (5) the infraorbital nerve to the upper gums and teeth, mucosa of the nasal floor, the skin below the eye, on part of the nose and the upper lip.

Mandibular Nerve.—The mandibular includes motor and proprioceptive fibres, in addition to sensory fibres. The latter are distributed (1) to the skin and inner mucous lining of the cheek by the buccinator nerve; (2) to the mucous membrane of the tongue by the lingual nerve; (3) to the lower teeth, lower lip and chin by the inferior alveolar nerve; and (4) to the skin of the auditory canal, eardrum and much of the external ear by the auriculotemporal nerve.

The motor fibres of the mandibular nerve arise in the motor trigeminal nucleus and emerge as the motor root, passing beneath the semilunar ganglion. They are distributed by branches of the

FIG. 4.—CUTANEOUS NERVES AND THEIR REGIONS IN THE HEAD AND NECK

nerve to the muscles of mastication, the temporal muscle and the tensors of the palate and eardrum.

The proprioceptive fibres arise from cells of the mesencephalic trigeminal nucleus, in the midbrain, and are distributed to the muscles of mastication with the motor root and its branches. Components related to proprioceptive fibres reach the teeth and gums through the alveolar branches of the mandibular and maxillary nerves.

Abducens Nerve.—The sixth cranial nerve takes origin from the abducens nucleus (fig. 1[A] and 3) and emerges from the forward surface of the medulla oblongata. Passing into the orbit it ends on the lateral rectus muscle. Save for possible proprioceptive fibres the abducens nerve is entirely motor.

Facial Nerve.—The seventh cranial nerve leaves the medulla oblongata by the principal or motor root and the smaller root called the intermediate nerve of Wrisberg (fig. 1[A] and 3). The two roots unite to form a common nerve trunk which enters the facial canal of the petrous bone. Within the canal it gives off a small branch to the stapedius muscle of the ear and one that joins the auricular branch of the vagus nerve, described below. On leaving the canal the facial nerve gives off branches to two muscles beneath the angle of the jaw and also branches to the muscles of facial expression.

The motor fibres derive from the facial nucleus. The intermediate nerve includes both motor and sensory fibres. The motor component consists of parasympathetic fibres from the superior salivatory nucleus and adjacent region. Those from the nucleus are preganglionic fibres that unite with the sensory fibres to form the chorda tympani. This nerve leaves the trunk of the facial nerve before the latter emerges from the facial canal, loops upward into the tympanic cavity and then downward and forward, joining the lingual branch of the trigeminus. The sensory fibres reach the taste buds on the anterior two-thirds of the tongue. The preganglionic fibres turn to the submaxillary and sublingual ganglia, from which postganglionic fibres lead to the glands similarly named.

Another contingent of preganglionic parasympathetic fibres leaves the trunk of the facial nerve just before it enters the facial canal and passes to the sphenopalatine ganglion by way of the great superficial petrosal nerve; postganglionic fibres distribute to the lacrimal gland and the mucous glands of the posterior nasal cavity. Sensory fibres of the intermediate nerve have their origin in the geniculate ganglion; their central processes form part of the solitary tract and end in the nucleus of this tract.

Acoustic Nerve.—The eighth cranial nerve includes two divisions, (1) the vestibular, serving equilibrium; and (2) the cochlear, which serves hearing (fig. 1[A] and 3). They are closely related in much of their course, but have separate central connections and peripheral distribution.

The fibres of the vestibular nerve arise in the vestibular ganglion, the central processes terminating in the vestibular nuclei. The peripheral branches of the nerve pass to the utricle, saccule and ampullae of the semicircular canals, the nerve fibres ending in relation to sensory hair cells.

The cochlear fibres arise in the spiral ganglion of the cochlea. The centrally directed processes terminate in the cochlear nuclei and the peripheral processes end in relation to hair cells of the organ of Corti, which are stimulated by sound waves.

Glossopharyngeal Nerve.—The ninth cranial nerve is attached to the side of the medulla oblongata by five to six linear rootlets (fig. 1[A]). It includes both motor and sensory fibres, the latter having their origin in the superior and inferior ganglia of the nerve. The central processes of those of the inferior ganglion pass into the solitary tract and end in its nucleus (fig. 3). The peripheral branches of the nerve distribute to the mucous membranes of the pharynx and middle ear and the posterior third of the tongue and to taste buds on this part of the tongue. The motor fibres include special visceral efferents from the nucleus ambiguus to muscles of the pharynx, soft palate and the stylopharyngeus muscle. Preganglionic parasympathetic fibres arise in the inferior salivatory nucleus and relay in the otic ganglion to the parotid gland.

Vagus Nerve.—The tenth cranial nerve is attached to the side of the medulla oblongata by eight to ten linear rootlets that converge to form the nerve trunk (fig. 1[A], 3 and 5). It has two ganglia, the superior and the inferior of the vagus. The superior ganglion gives off meningeal and auricular branches; the auricular distributes to the skin of part of the ear and external auditory canal. The inferior ganglion gives rise to the pharyngeal and superior laryngeal nerves. The former joins the pharyngeal branch of the glossopharyngeus as sensory supply to the mucous membrane of the pharynx. The superior laryngeal nerve is sensory to the mucous membrane of the larynx and base of the tongue; it includes motor fibres to one muscle of the larynx and one of the pharynx.

The recurrent laryngeal nerve branches from the vagus in the neck and supplies the remaining muscles of the larynx and the inferior constrictor of the pharynx; it also provides sensory fibres to the mucous membrane of the larynx below the vocal cords.

Parasympathetic fibres from the dorsal motor nucleus of the vagus pass through cardiac branches of the nerve, through the cardiac plexus in the chest, to the heart, in which their ganglia are situated. Branches also contribute to the esophageal and pulmonary plexuses, relaying in ganglionic clusters in the plexuses and in the esophagus, trachea, bronchi and lungs to reach the involuntary muscle and glands of these organs.

The vagus continues into the abdomen, supplying the parasympathetic innervation of the greater part of the digestive tract and other abdominal viscera through the gastric, celiac and other plexuses, which also include sympathetic fibres.

The right and left vagus nerves differ somewhat in course and specific distribution. Visceral afferent fibres from the thoracic

and abdominal organs, with cells in the inferior ganglion, enter the solitary tract and its nucleus. The somatic afferents from the skin end in the spinal trigeminal nucleus.

Spinal Accessory Nerve.—The 11th cranial nerve comprises a spinal part and an accessory part (fig. 1[A] and 3), both motor. The accessory part arises chiefly from the nucleus ambiguus and the spinal part from the motor column of the upper five or six segments of the spinal cord. The accessory part joins the vagus and accompanies its branches to the pharynx. The spinal part contributes to the innervation of two muscles of the neck which are of branchial origin.

Hypoglossal Nerve.—The 12th cranial nerve arises from the hypoglossal nucleus, its fibres emerging by numerous rootlets that converge into one trunk (fig. 1[A] and 3). This gives off branches to the musculature of the tongue, which in origin is related to myotomic muscles. Proprioceptive fibres have been described in the hypoglossal nerve. (*See* also TONGUE.)

SPINAL NERVES

The spinal nerves are named and numbered according to the region of the spinal cord to which they attach. (*See* SPINAL CORD.) There are 8 cervical (abbreviated C.), 12 thoracic (T.), 5 lumbar (L.), 5 sacral (S.) and usually 1 coccygeal (Co.).

Each spinal nerve has two roots, a dorsal or posterior (meaning "toward the back") and a ventral or anterior (meaning "toward the front") (fig. 1[B]). The dorsal root is sensory and the ventral root motor ("the law of the roots"); the first cervical nerve may lack the dorsal root. Oval swellings, the spinal ganglia, characterize the dorsal roots; they are formed of nerve cells that give rise to the sensory nerve fibres. The fibres of the ventral roots derive from cells in the anterior gray column (ventral horn) of the cord.

Central processes of the dorsal root fibres end in the posterior gray column (dorsal horn) of the cord or ascend to nuclei in the lower part of the brain. Immediately lateral to the spinal ganglia the two roots unite into a common nerve trunk which includes both sensory and motor fibres; the branches of this trunk distribute both types of fibres.

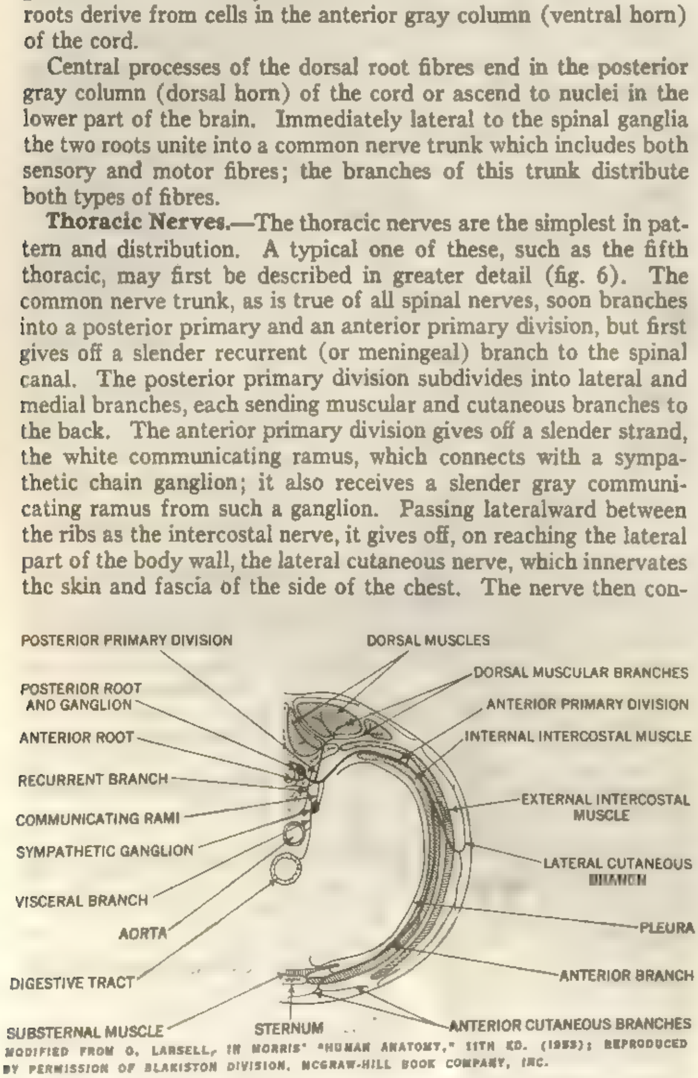
Thoracic Nerves.—The thoracic nerves are the simplest in pattern and distribution. A typical one of these, such as the fifth thoracic, may first be described in greater detail (fig. 6). The common nerve trunk, as is true of all spinal nerves, soon branches into a posterior primary and an anterior primary division, but first gives off a slender recurrent (or meningeal) branch to the spinal canal. The posterior primary division subdivides into lateral and medial branches, each sending muscular and cutaneous branches to the back. The anterior primary division gives off a slender strand, the white communicating ramus, which connects with a sympathetic chain ganglion; it also receives a slender gray communicating ramus from such a ganglion. Passing lateralward between the ribs as the intercostal nerve, it gives off, on reaching the lateral part of the body wall, the lateral cutaneous nerve, which innervates the skin and fascia of the side of the chest. The nerve then continues forward, as the anterior branch, to the border of the breastbone where it turns outward and forms the anterior cutaneous branch to the front of the chest. Throughout its course the intercostal nerve sends twigs to the intercostal muscles.

The functional types of fibres in the fifth and other thoracic nerves include (1) somatic afferents and efferents to the body wall, (2) autonomic fibres of the sympathetic division; and (3) visceral afferents from the internal organs.

The preganglionic sympathetic fibres take origin in the lateral part of the ventral horn of the cord; all pass through the anterior roots, common nerve trunk and white communicating rami to the sympathetic chain ganglia. Some end in these ganglia, while others continue through splanchnic nerves to the celiac and mesenteric ganglia of the abdomen. Postganglionic fibres from the chain ganglia pass through the gray rami to the common nerve trunk and are distributed by its branches to sweat glands, erector muscles of the hairs and blood vessels. Those arising in the celiac and mesenteric ganglia pass through the celiac, mesenteric and subsidiary plexuses to the internal organs.

The visceral afferent fibres from the internal organs reach the spinal cord without interruption by way of the splanchnic nerves, sympathetic ganglia, white rami, common nerve trunk and the dorsal roots.

Other thoracic nerves show various departures from the pattern of the fifth. The first thoracic nerve enters also into the formation of the brachial plexus, described below. The second thoracic nerve gives off the intercostobrachial nerve to the skin of the armpit and medial side of the arm (fig. 7). The third thoracic nerve sends a lateral cutaneous branch to the skin of the medial side of the base of the arm, which usually joins the intercostobrachial nerve. The 7th to 12th thoracic nerves continue obliquely into the wall of the abdomen, providing branches to its muscles and to the skin and fascia as far down as the crest of the hipbone and onto the buttock. The 12th nerve frequently sends a connection to the lumbar plexus, described below. The cutaneous branches of a given thoracic nerve supply not only its own body segment but overlap onto adjacent segments above and below it. Each segment, accordingly, is innervated by cutaneous branches of three spinal nerves (fig. 7). The intercostal nerves also send



MODIFIED FROM O. LARSELL, IN MORRIS' "HUMAN ANATOMY," 11TH ED. (1953); REPRODUCED BY PERMISSION OF BLAKISTON DIVISION, MCGRAW-HILL BOOK COMPANY, INC.

FIG. 6.—DIAGRAM SHOWING DISTRIBUTION OF A TYPICAL SPINAL NERVE

numerous twigs to the linings of the thorax and abdomen.

The innervation of the skin of the shoulder, upper extremity, lower part of the body and lower extremity overlaps as in the trunk but in a less regular pattern. Tests after injury to individual sensory nerve roots have revealed longitudinal zones of reduced sensibility, some extending from the lower neck or upper trunk to the hand, or from the lower back or the buttock to the foot. These indicate the areas primarily supplied by individual spinal nerves.

Spinal Nerve Plexuses.—The cervical, lumbar, sacral and coccygeal nerves all receive gray rami from the sympathetic chain ganglia, but only the upper lumbar, in addition to the thoracics, have white communicating rami. The posterior primary divisions of all, according to their regions of origin, pass to the muscles of the back that are associated with the axial skeleton, and to the skin and fascia of the back of the head and neck, the back, medial part of the buttock, and that overlying the coccyx or tail bone.

The anterior primary divisions of all these nerves are arranged in a series of plexuses, namely, the cervical, brachial, lumbar, sacral and coccygeal, in which fibres from the individual spinal nerves are regrouped before entering the nerves of distribution.

Cervical Plexus.—The cervical plexus is formed from the first four cervical nerves as a series of loops whose branches include fibres of two or more upper cervical nerves. These branches supply the skin of the head, neck and shoulder and the muscles of the neck and diaphragm, with the result that the skin areas, especially, have multiple innervation. The nerves to the muscles, as a rule, do not form loops but are arranged as medial and lateral groups.

Brachial Plexus.—This plexus (fig. 8) is derived from the fifth to the eighth cervical nerves and the greater part of the first thoracic. These first form three trunks—the superior, medial and inferior—and then recombine through anterior and posterior divisions of each trunk into three cords.

The plexus is divided into supraclavicular and infraclavicular parts. Before the cords are reached the supraclavicular part gives off the long thoracic (C. 5, 6, 7), dorsal scapular (C. 5), subclavian (C. 4, 5, 6) and suprascapular (C. 4, 5, 6) nerves. These supply muscles of the shoulder girdle, the suprascapular also innervating the joint between the collar bone and the acromion process.

The infraclavicular part comprises the three cords—lateral, medial and posterior—from which are derived the nerves of distribution to the shoulder and upper extremity. Each cord is composed of fibres from several of the lower cervical nerves. Some include both sensory and motor fibres, while others have only cutaneous or muscular fibres. The segmental source of the muscular supply does not necessarily correspond to that of the overlying skin.

The lateral cord gives off (1) the lateral anterior thoracic nerve (C. 5, 6, 7), to the breast muscles; (2) the musculocutaneous nerve (C. 4, 5, 6), to the muscles of the front of the arm and to the skin of the side of the forearm; and (3) the median nerve (C. 5, 6, 7, 8; T. 1), to certain muscles of the forearm, thumb and fingers, to the skin of the palm, hand and fingers and to the elbow, wrist and hand joints.

The medial cord branches into (1) the ulnar nerve (C. 8; T. 1), to flexor muscles of the wrist and fingers, most of the muscles of the hand, to the skin of the medial part of the hand and to the joints of the elbow, wrist and long bones of the hand; (2) the medial brachial cutaneous nerve (C. 8; T. 1), to the skin of the medial side of the arm and forearm; and (3) the medial anterior thoracic nerve (C. 8; T. 1), to the breast muscles.

The posterior cord divides into (1) the axillary nerve (C. 5, 6), to shoulder muscles and joint and to the skin of the lateral part of the shoulder and arm; and (2) the radial nerve (C. 5, 6, 7, 8), to muscles of the arm and forearm and to the skin of the back of the arm and hand, also to elbow, wrist and hand joints and, through its (a) subscapular (C. 5, 6) and (b) thoracodorsal (C. 6, 7, 8) branches, to muscles related with the humerus and shoulder girdle.

Lumbosacral Plexus.—The lumbar, sacral and coccygeal nerves form the lumbosacral plexus, subdivided into lumbar and sacral plexuses.

The lumbar plexus (fig. 9) usually involves the first three and part of the fourth lumbar nerves. Most of the first lumbar, however, is distributed much like a thoracic nerve. The plexus first gives off the iliohypogastric (L. 1) and ilioinguinal (L. 1) nerves, which pass around the abdominal wall in its muscles, into which they send twigs. The iliohypogastric also supplies the skin and fascia of the upper and lateral parts of the buttock and above the pubis. The ilioinguinal supplies the skin of the upper part of the thigh and part of the external genitals. The remaining branches of the plexus are: (1) the obturator nerve (L. 2, 3, 4), to the muscles and skin of the inner side of the thigh and to the hip and knee joints; (2) the genitofemoral nerve (L. 1, 2), to the skin of the upper part of the thigh and of the scrotum or major labium; (3) the lateral femoral cutaneous nerve (L. 2, 3), to the skin of the lateral part of the thigh; (4) the femoral nerve (L. 2, 3, 4) to the iliac muscle and muscles on the front of the thigh, to the hip and knee joints, to the skin on the front and inner side of the thigh and, through the saphenous nerve, to the leg and foot.

The sacral plexus (fig. 9) is formed from the fourth and fifth lumbar and the first four sacral nerves, the lumbosacral trunk con-

FIG. 9.—PLAN OF THE LUMBAR AND SACRAL PLEXUSES AND NERVES

necting the first two with the first sacral. The divisions of the fourth and fifth lumbar and the first three sacral nerves are gathered into the sciatic or ischiadic nerve, which runs down the back of the thigh. The sciatic nerve divides in the space behind the knee joint to form the common peroneal and tibial nerves. The common peroneal nerve (L. 4, 5; S. 1, 2) supplies a muscle that flexes the knee joint and fibres to this joint. After passing a short distance down the posterior portion of the lower leg, the common peroneal nerve bifurcates into deep and superficial portions. The deep peroneal nerve passes to muscles of the lower leg and the foot, to toe muscles, to skin between the first and second toes and to the joints of the ankle and foot. The superficial peroneal nerve supplies muscles of the foot, the skin of the lower lateral part of the leg and upper surface of the foot. The tibial nerve (L. 4, 5; S. 1, 2, 3) innervates muscles of the back of the leg and the foot, the skin of the back of the leg and the knee and ankle joints.

Branches from the sacral plexus pass to the muscles of the hip and buttock and to the skin of the buttock. The pudendal nerve (S. 2, 3, 4) contributes to supply the skin and muscles of the perineum (the region of the outlet of the pelvis) and the genital organs. The posterior cutaneous nerve of the thigh (S. 2, 3, 4) innervates the skin of the posterior part of the buttock, thigh and perineum. Variable perforating cutaneous branches (S. 2, 3) pass to the skin of the buttock. Sacral parasympathetic fibres emerge with the second and third or third and fourth sacral nerves, pass through the pelvic plexus and terminate in ganglionic clusters in the plexus or in the walls of the organs supplied. Postganglionic fibres reach the lower part of the colon, the rectum, bladder and lower ureter and the genital organs.

Coccygeal Plexus.—The coccygeal plexus is formed from the fourth and fifth sacral and the coccygeal nerves. It sends small branches to muscles of the floor of the pelvis and to the skin over the coccyx.

(O. LL.)

NERVE CONDUCTION, the process by which the nerve fibres carry messages throughout the bodies of multicellular animals. In the higher animals, information about the outside world or the state of the animal's body is conveyed along sensory nerves to the central nervous system, which sorts out the information and issues appropriate orders to the muscles or glands. The outgoing information travels in motor nerves and reaches the muscles after crossing a special region between nerve and muscle. In vertebrates, the nerve cell bodies, from which nerve fibres arise, are situated in or near the spinal cord. The cell bodies are essential for the growth and maintenance of nerve fibres, but not for the conduction of impulses. Fibres which have been separated from their cell bodies are able to conduct impulses for several hours or days but do not survive indefinitely, either inside or outside the animal. On the basis of their appearance under the microscope, nerve fibres may be divided into two distinct classes. In myelinated fibres, which form the bulk of human nerves, the protoplasmic core of the fibre is surrounded by a sheath of a fatty substance known as myelin. The sheath is interrupted at intervals of about one millimetre by a short gap called the node of Ranvier. In unmyelinated fibres there is no fatty sheath and the fibre consists of a cylinder of protoplasm separated from the external medium by a membrane whose thickness is probably of the order of one-millionth of a centimetre. A similar membrane is almost certainly present at the node of Ranvier.

The diameter of most nerve fibres is usually 0.001 to 0.02 mm. but certain invertebrates possess very large unmyelinated fibres and in the extreme case of the squid these may be as much as one millimetre in diameter. The length of nerve fibres varies from a fraction of a millimetre in a small insect to many metres in the largest mammals.

The protoplasmic core of the fibre is an aqueous solution and a reasonably good conductor of electricity. It contains a high concentration of potassium ions and a low concentration of sodium and chloride ions. This is the reverse of the animal's blood, in which sodium and chloride are the dominant ions and potassium ions are relatively dilute.

In contrast to the protoplasm, the membrane at the surface of the fibre is a moderately good insulator, and this helps to prevent the contents of the fibre from mixing rapidly with the external solution. In addition, much of the cells' metabolism is probably directed toward maintaining a state of unequal ionic concentration across the surface membrane.

Nervous messages are invariably accompanied by brief electrical changes, known as action potentials. When a sense organ is stimulated, or when the central nervous system issues an order to a muscle, electrical impulses can be recorded from the nerve which would be expected to be carrying information. Fig. 1 illustrates trains of action potentials traveling to and from the central nervous system in two nerves that control the respiration of a cat.

FIG. 1.—ELECTRICAL IMPULSES IN THE RESPIRATORY NERVES OF A CAT

(A–C) Sensory impulses traveling from the lungs to the brain in the vagus nerve. White lines indicate the degree of inflation of the lungs. The impulses, recorded with external electrodes from a strand of the nerve trunk, appear as black vertical lines. The deflections produced by the impulses are shown downward and the frequency of the impulses rises as the distension of the lungs is increased

(D–G) Motor impulses traveling to the diaphragm in the phrenic nerve. Upper tracing indicates the respiratory movement; impulses are shown below as upward deflections. One fibre carries the impulses in (D), two in (E) and (F), and three in (G)

The action potentials which carry information along the nerve fibres last about $\frac{1}{1,000}$ sec. and travel at speeds of 1–100 m. per second (100 m. per second is equal to 224 m.p.h.). The velocity of conduction is greater in large fibres than in small, and myelinated nerve fibres conduct faster than unmyelinated fibres of comparable size. However, in any one fibre, the size and velocity of the action potential is constant and cannot be altered by changing the strength or quality of the stimulus. In other words, provided that a stimulus is strong enough to evoke an impulse, the size of the action potential in a single fibre is independent of the strength of the stimulus. This invariance of the action potential arises because the energy used in propagation does not come from the stimulus but is released by the nerve along its length. In this respect, nervous conduction resembles the burning of a fuse of gunpowder and is unlike the propagation of an electric signal along a cable or telephone wire. (*See* also ALL-OR-NONE LAW.)

For many years physiologists suspected that the electrical changes in nerve arose at the surface membrane. This idea was verified by experiments in which the electrical potential difference across the surface of the fibre was measured directly with an internal electrode (figs. 2 and 3). In such experiments it is found that the inside of the fibre is usually about 0.07 v. negative to the external solution; this difference in electrical potential is known as the resting potential. When an impulse travels along

FIG. 2.—METHODS OF RECORDING ELECTRICAL CHANGES ACROSS THE SURFACE MEMBRANE OF A NERVE FIBRE

(A) Longitudinal insertion of internal electrode, used with giant nerve fibre. (B) Transverse insertion of internal electrode used with nerve or muscle fibres and other cells. The electrical recording system consists of a vacuum tube amplifier and cathode ray oscillograph. (1 $\mu = \frac{1}{1,000}$ mm.)

the fibre, the inside swings momentarily positive, giving a transient action potential of amplitude 0.1–0.12 v. At the crest of the action potential the inside of the fibre is about 0.04 v. positive to the outside.

When a brief electric current is applied to a nerve it is found that the impulse always arises at the cathode. This means that the event which starts the impulse is a decrease of the electrical potential difference across the membrane. The amount by which the potential difference must be reduced is naturally somewhat variable but under most conditions is about 0.02 v.

Shortly after a stimulus has evoked a response, the nerve enters an absolute refractory period, during which no stimulus, however strong, can evoke a second response. The absolute refractory period lasts for about $\frac{1}{1,000}$ sec. and is followed by the relative refractory period during which a second impulse can be evoked, but only by a stimulus which is stronger than normal.

Although nerve fibres normally conduct impulses in one particular direction (toward the central nervous system in sensory fibres, away from it in motor fibres), all nerves can conduct impulses in both directions, and the velocity at which the impulse propagates is independent of the direction in which it is traveling.

The conductivity of the surface membrane increases greatly during an impulse, and sodium and potassium ions cross the membrane more easily than in the resting state. The net effect of an impulse is that a small quantity of sodium ions enters the fibre and a corresponding amount of potassium ions leaves it. These movements, which are both down concentration gradients, are thought to provide the immediate source of energy for propagation and must be reversed by a metabolic process operating during the period of recovery which follows a burst of electrical activity.

FIG. 3.—ACTION POTENTIAL, TRAVELING TOWARD MUSCLES, IN THE GIANT NERVE FIBRE OF THE SQUID, RECORDED FROM A NERVE FIBRE IN ITS NATURAL POSITION IN THE WHOLE ANIMAL

The record shows the electrical potential difference between the inside of the fibre and the external fluid (1 mv. = $\frac{1}{1,000}$ volt). Dots below the record correspond to a frequency of 2,500 per second. The brief excursion at the beginning of the record occurred at the moment when the electric shock, which started the action potential, was applied to the nerve. The temperature was 8.5° C.

Mechanism of Nervous Conduction.—Many of the facts described in this article are explained by a hypothesis which is essentially a modification of the membrane theory, proposed early in this century by Bernstein, Overton and Lillie. According to this hypothesis, the resting membrane is impermeable to sodium ions but is moderately permeable to potassium ions. Since potassium ions are more concentrated inside the fibre, they tend to move outward, and this makes the inside of the fibre negative with respect to the external solution. Evidence for this idea is provided by the observation that the resting potential disappears if the concentration of potassium in the external solution is made equal to that inside the fibre.

When the potential difference across the resting membrane is reduced by an external electric current, or by the approach of the active region, the properties of the membrane change in a remarkable way. The molecular nature of this change is entirely unknown, but it always involves an increase in the conductivity of the membrane and its effect appears to be that the membrane undergoes a large but transient increase in the permeability to sodium ions. Since sodium ions are more concentrated outside the fibre, they enter it and make the inside of the membrane positive. The change in permeability generates the action potential and the movement of sodium ions provides the inward current on which conduction of impulses depends.

The way in which the impulse propagates in an unmyelinated fibre is illustrated in the upper part of fig. 4. Suppose that point A is active and that B is resting. A is sodium permeable so the inside of the fibre is positive; B is potassium permeable so the inside is negative. Electric current therefore flows in a local circuit between resting and active nerve and this reduces the potential difference just ahead of the active region. When the potential difference at B is reduced by about 0.02 v. the permeability to sodium rises and the inside of the fibre becomes positive. Point B is now active and can stimulate the next region in precisely the same manner. In this way a wave of increased sodium permeability spreads along the fibre.

Since the increase in sodium permeability is transient, the membrane does not remain in the active state but returns to its original condition after about $\frac{1}{1,000}$ sec. The restoration of the normal potential difference is brought about by an outward movement of potassium ions and is accelerated by a rise in potassium permeability, which takes place later than the initial rise in sodium permeability.

FIG. 4.—DIAGRAMS ILLUSTRATING PROPAGATION OF THE NERVE IMPULSE IN (TOP) AN UNMYELINATED FIBRE AND (BOTTOM) A MYELINATED FIBRE. THE ARROWS SHOW THE DIRECTION OF THE ELECTRIC CURRENT

Like most other theories of nervous conduction, the one just

outlined assumes that the causal agent in propagation is the electric current which flows between resting and active nerve. This assumption is supported by extremely strong evidence and is accepted by those who have reservations about the part played by the sodium and potassium ions in generating the action potentials.

Unmyelinated fibres are continuous structures and the impulse propagates smoothly from one point to the next. In myelinated nerve fibres, which are present in all vertebrates and in shrimps and prawns, a different type of conduction has been evolved. Here most of the fibre is covered with an insulating layer and the excitable membrane is exposed only at the nodes of Ranvier. When one node becomes active, current flows through the next node in the manner shown in fig. 4.

In this system only the nodes generate the action potential, and the function of the myelin is to make the local electric current act at some distance ahead of the active point. The effect of this type of propagation, which is known as saltatory conduction, is that the impulse is conducted at a higher velocity and with greater economy than in an unmyelinated fibre of comparable size.

NERVI, PIER LUIGI (1891–), internationally known Italian structural engineer, was born in Sondrio, Italy, June 21, 1891, and graduated from the University of Bologna in 1913. He later joined the staff of the School of Architecture of Rome, teaching technology and construction technique. His most important works are several large-span structures built in Italy—the municipal stadium in Florence (1929); aircraft hangars with geodesic structure at Orvieto, Orbetello and Torre del Lago (1936–41), all destroyed during World War II; a complex for the Turin exhibition (1948–50); the permanent headquarters of the United Nations Educational, Scientific and Cultural organization at Paris, in collaboration with Marcel Breuer and B. Zehrfuss, architects; and the Olympic sport palace and the Flaminio stadium, both built in Rome, and the stadium of Taormina, in Sicily.

In 1956 Nervi went to the United States to lecture on his work at the invitation of several universities. He is an honorary member of the American Academy Institute of Arts and Letters (1957) and of the American Institute of Architects, and a member of the National Association of Italian Engineers and Architects and of the International Congress of Contemporary Architecture.

(E. F. C.)

NERVO, AMADO (1870–1919), recognized as Mexico's best modernist poet, was born in Tepic, Mex., on Aug. 27, 1870, and was originally named Amado Ruiz de Nervo. He studied at the Colegio de Jacona and at the seminary of Zamora from 1886 to 1888. Nervo's literary career was begun in Mazatlán as a newspaperman. From there he went to Mexico City in 1894, where he published his short novel *El Bachiller* (1895), his first volume of poems *Perlas Negras* (1898) and also wrote for the *Revista azul*. With J. E. Valenzuela he founded the modernist periodical *Revista moderna* (1898–1903). From 1905 to 1918 he lived in Madrid, Spain, as secretary to the Mexican legation; and there he wrote most of his innumerable poems, essays and short stories. After a short visit to Mexico in 1918 he was appointed minister to Argentina and Uruguay. He died in Montevideo on May 24, 1919. His best poems, found in the volumes *Elevación* (1914–16) and *Plenitud* (1917) are characterized by a deep religious feeling and a simple but perfect form.

(L. LL.)

NERVOUS SYSTEM. The nervous system may be divided into (1) the central nervous system, consisting of the brain and spinal cord and (2) the peripheral nervous system, consisting of the cranial, spinal and peripheral nerves with their motor and sensory endings.

The anatomy and physiology of many parts of the nervous system are treated in separate articles (*see* BRAIN; CIRCULATION OF BLOOD; DIGESTION; EAR, ANATOMY OF; EYE, HUMAN; MUSCLE AND MUSCULAR SYSTEM; NERVE; NERVE CONDUCTION; NEUROLOGY, COMPARATIVE; OLFACTORY SYSTEM; SMELL AND TASTE; SPINAL CORD; TOUCH).

HISTOLOGY

The organs and organ systems of the body are composed of tissues, and these in turn are composed of microscopic units termed cells. Cells are specialized to perform a particular function, such as secretion (gland cell), contraction (muscle cell) or conduction (nerve cell). The nervous system is composed of billions of individual cells. The most noted investigator of the histology (microscopic anatomy) of these cells was the Spanish scientist Santiago Ramón y Cajal.

Nerve Cells.—Nerve cells or neurons are distinguished by processes (projections) that conduct nerve impulses to and from the body of the cell. Nerve impulses are physicochemical reactions that sweep along the surfaces of neurons and their processes (*see* NERVE CONDUCTION). Similar reactions occur in many other types of cells, but are most notable in neurons, the structural features of which are designed to transmit impulses over long distances to many parts of the body.

The bodies of neurons vary in diameter from 4–5μ (microns)

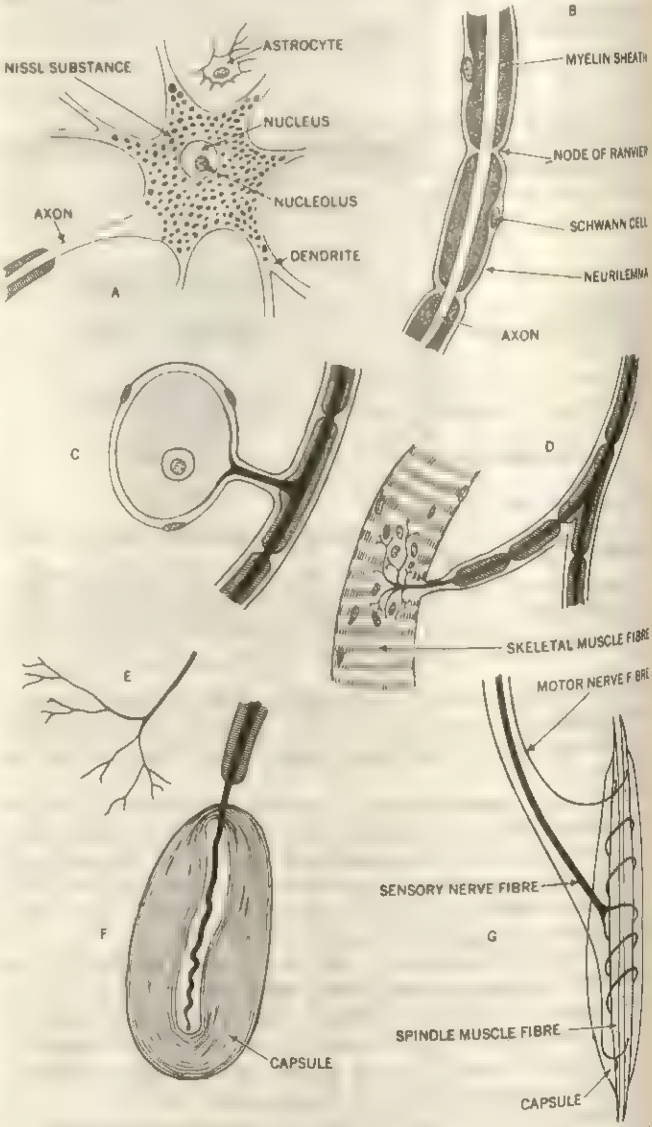

FIG. 1.—DIAGRAMS OF NERVE CELLS AND ENDINGS AT HIGH MAGNIFICATIONS

(A) Multipolar cell of spinal cord; (B) part of a myelinated nerve fibre; (C) unipolar cell; (D) motor end plate; (E) nonmyelinated fibre forming a free ending; (F) Pacinian corpuscle; (G) neuromuscular spindle, present in muscles near the junction of muscle and tendon

up to 50–100μ (a micron is about $\frac{1}{25,000}$ in.). The largest neurons are almost visible to the naked eye. The nuclei of cells contain a material called chromatin; chromatin in the nuclei of neurons is sparse in amount, although the nucleolus is very prominent. The cytoplasm of neurons contains a chromatinlike material called Nissl substance (named after Franz Nissl) (fig. 1[A]). The cytoplasm also contains special particles called mitochondria, and a complex, lipoid structure, the Golgi apparatus (after Camillo Golgi). Both are important in metabolic processes and both are present in other types of cells. Thin fibrils termed neurofibrils are also present in the cytoplasm and processes of nerve cells; their significance is unknown.

The processes of neurons may be only a few microns in length, or they may extend several feet. Processes that conduct impulses away from the cell body are termed axons. A neuron generally has only one axon. Processes that conduct toward the cell body are called dendrites. Most neurons have many dendrites and are classified as multipolar cells (fig. 1[A]). The neurons of the brain, spinal cord and autonomic ganglia are multipolar. The neurons of spinal ganglia and of the ganglia of certain cranial nerves are unipolar; that is, they have only one process (fig. 1[C]). This process divides into two branches, one of which conveys impulses from sensory endings toward the cell body, while the other conveys these impulses to the brain or spinal cord. Certain neurons in ganglia of the inner ear, in one of the layers of the retina of the eye and in the olfactory mucous membrane have two processes and are classified as bipolar. One process conducts toward, and the other away from, the cell body. The processes of unipolar and bipolar cells are structurally similar to the axons of multipolar cells.

The dendrites of multipolar cells are short branching processes that contain Nissl substance and mitochondria. The branching increases the surface area of the cell. Axons (and the processes of unipolar and bipolar cells) lack Nissl substance but contain mitochondria. They often extend for long distances, and have few branches until near their terminations. If an axon is more than about one micron in diameter, it is surrounded by a whitish, lipoid sheath, the myelin or medullary sheath (fig. 1[B]). This sheath is interrupted at regular intervals to form nodes of Ranvier (after Louis Ranvier), which are of fundamental importance in nerve conduction. The largest axons, with their myelin sheaths, are no more than about 20μ in diameter. All axons of the peripheral nervous system, whether they have a myelin sheath or not, are surrounded by a thin, protoplasmic sheath, the neurilemma. This sheath is a cellular tube formed by cells of Schwann (after Theodor Schwann). It is of fundamental importance in the formation of myelin and in nerve regeneration. There are no neurilemmal cells in the central nervous system.

The term nerve fibre is often used to specify an axon and its various sheaths; hence the terms myelinated fibre and nonmyelinated fibre. The gray matter of the central nervous system is composed mainly of cell bodies and fibres that, for the most part, are nonmyelinated. By contrast, white matter contains large numbers of myelinated fibres and relatively few cells. A nerve is a collection of nerve fibres that is visible to the naked eye; the constituent fibres are bound together by connective tissue. Each fibre is microscopic in size, hence hundreds or thousands of fibres are present in each nerve. Thus, according to the number of constituent fibres, a nerve may be barely visible or it may be quite thick.

Nerve Endings.—Nerve fibres carry impulses to and from nonnervous structures (such as muscle), and they end in a special way in relation to these structures. They also transmit impulses to other nerve cells and have special endings at the points of transmission.

Sensory Endings (Receptors).—When skin is stimulated so that the sensation of touch is aroused, the stimulus activates certain special structures in the skin. These structures are receptors, composed of nerve fibres and nonnervous tissue, so arranged that when mechanically deformed by the stimulus, they discharge nerve impulses to the brain or to the spinal cord. Receptors are further specialized according to the type of stimulus to which they are most sensitive; *e.g.*, the retina of the eye is activated by radiant energy, taste buds of the tongue by chemical reactions.

Receptors for the special senses (vision, hearing, balance, taste and smell) are described in other articles. Receptors for the general senses (touch, pain, temperature, pressure, position and movement) are of several varieties that differ mainly in the way in which the nonnervous tissue is arranged. The simplest are those in which a nerve fibre breaks up into fine branches that end in connective tissue or in epithelium; these are free nerve endings (fig. 1[E]).

In other receptors, the nerve fibres end in a complicated branching, surrounded by a specialized connective tissue capsule. Such endings are often called corpuscles; they are most sensitive to mechanical deformation. The nerve fibres to corpuscles are usually myelinated, but the myelin is lost before the fibre enters the corpuscle.

The sensations of touch, pain and temperature can be aroused from skin. The only receptors in hairy skin are free endings and complicated plexuses around hair follicles. In skin without hair, such as on the finger tips, there are also oval, encapsulated endings known as Meissner's corpuscles (after George Meissner) and believed to be touch receptors. Other types of corpuscles may also be present. Some receptors in skin are sensitive to mechanical deformation (pressure), others to injury (pain) and others to radiant energy (temperature). Further correlation between structure and function is quite speculative.

The Pacinian corpuscle (after Filippo Pacini) has a capsule arranged in layers like an onion (fig. 1[F]). This corpuscle is often large enough to be visible to the naked eye. It is present in the deeper parts of skin and in the subcutaneous tissues, and in these locations is believed to be concerned with the sensation of pressure (deep touch). Pacinian corpuscles are present in and around muscles, joints, ligaments and tendons. Other complex receptors are also found in these structures. One is the neuromuscular spindle (fig. 1[G]), which is so constructed that it is deformed if the muscle is stretched. Hence it is sensitive to a change in muscle length and on that account is often called a stretch receptor. Neurotendinous spindles are stretch receptors in tendons. A Ruffini ending (after Angelo Ruffini) is a stretch receptor in ligaments and joints; it lacks a definite capsule. The various receptors in muscles, joints, ligaments and tendons are concerned with the sensations of position and movement. Free endings are also present in these structures and are believed to be associated with pain.

Viscera also contain receptors. Some are concerned with pain and others with sensations, but most are involved in the reflex control of visceral activity. For example, some viscera contain Pacinian corpuscles, the positions of which near blood vessels suggest that they are sensitive to changes in vessel diameter due to pulsation. Many viscera and blood vessels contain endings that resemble stretch receptors. Those in blood vessels are activated when the vessel walls are stretched during dilatation of the vessels, and the resulting impulses are transmitted to neurons in the brain that are concerned with the reflex control of blood pressure.

Motor Endings.—Motor impulses to the heart, glands and smooth muscle are carried by small nerve fibres of the autonomic system. The way in which they end is still obscure. Presumably they form simple, free endings in these structures.

Skeletal muscle fibres are supplied by large motor nerve fibres that are axons of cells in the brain and the spinal cord. When such an axon enters a muscle (hundreds or thousands usually enter each muscle) it divides into many smaller branches. Each branch ends on a muscle fibre as a ramification that is surrounded by muscle fibre nuclei and is termed a motor end plate or myoneural junction (fig. 1[D]). The myelin sheath ends before the muscle fibre is reached, and the neurilemma becomes continuous with the cell membrane of the muscle fibre. The arrival of a nerve impulse at a motor ending is followed by the contraction of the muscle fibre.

Neuronal Junctions (Synapses).—When an axon approaches a neuron to which it is conveying an impulse, it decreases in diameter and divides repeatedly. Each branch ends by making contact with

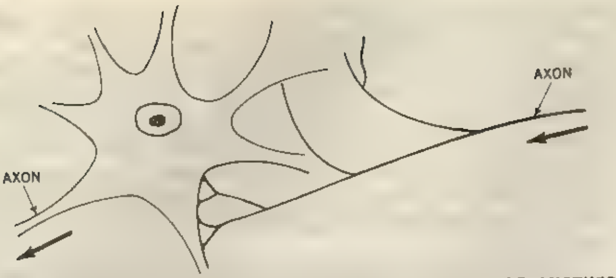

FIG. 2.—DIAGRAM OF A MULTIPOLAR CELL SHOWING AXON OF ANOTHER CELL SYNAPSING ON ITS SURFACE. HEAVY ARROWS INDICATE DIRECTION OF CONDUCTION

the surface of a dendrite or of the cell body (fig. 2), generally as a small swelling that may have a ringlike appearance. The branch may make several contacts before it ends. These contacts or junctional regions are called synapses. The axon and the cell with which it is synapsing are not fused. This "contiguity without continuity" has been demonstrated by electron microscopy. It is the basis of the neuron theory; *i.e.*, that neurons are cellular units.

Some of the terminal branches of an axon may synapse with one neuron, others with another, so that one axon may make contact with hundreds of neurons. Conversely, any one neuron may have hundreds or thousands of synaptic contacts on its surface, derived from many axons. Nerve impulses usually cross synaptic junctions in only one direction, namely from the axon of one neuron to a dendrite or the cell body of the next neuron.

Neuroglia.—The central nervous system contains blood vessels and a small amount of connective tissue around the vessels. Otherwise the nonnervous elements consist of cells known collectively as neuroglia. Glial cells differ in size and shape; nearly all have processes that weave around cells and fibres, and are frequently attached to the walls of blood vessels. Some glial cells have many processes and, because of their shape, are known as astrocytes (fig. 1[A]). Others, with fewer and shorter processes, are termed oligodendroglia. Both types develop embryologically from cells of the neural tube. Another type of glial cell is derived embryologically from connective tissue cells carried in with blood vessels. These cells are small and have few processes; they are called microglia. The lining of the cavities of the brain and the spinal cord is called ependyma; its cells constitute a special type of neuroglia.

Most glial cells can act as phagocytes; that is, they can ingest and remove dead or injured nervous tissue. There is evidence that glial cells are also concerned with the formation of myelin. Glial cells are clinically important because all tumours that begin in the brain and spinal cord are composed of glial cells.

Degeneration and Regeneration.—Adult neurons cannot divide and form new cells. Hence, a neuron that is lost cannot be replaced. If an axon is destroyed, however, the cell body may survive, although it undergoes certain changes. For example, if the axon of a spinal cord neuron is severed by cutting a peripheral nerve, the Nissl substance in that cell disappears (chromatolysis), but may reappear after several weeks or months; however, neurons confined entirely to the central nervous system generally do not survive axonal section. That part of the axon separated from the cell body degenerates; the myelin sheath and the axon swell and disintegrate. The fragments are removed by scavenger cells, most of which are proliferating neurilemmal cells. These cells remain as a cellular cord. The tip of that part of the axon still connected with the cell body begins to grow through the neurilemmal cord (at the rate of about one to two millimetres a day in man) and eventually reestablishes contact with whatever structure it had previously innervated. Function is often restored more or less completely. The myelin sheath is reformed, probably by neurilemmal cells.

There is no significant regeneration in the brain and spinal cord of warm-blooded animals; it may occur to a striking degree in many cold-blooded animals, however.

EMBRYOLOGY

Early in embryonic development, a neural tube is formed in the manner illustrated in fig. 3. This figure also shows that the head end of the neural tube early in development has three and then five enlargements from which the adult brain is derived. The rest of the tube forms the spinal cord. In spite of complex changes during growth and maturation, the central nervous system retains the cavity of the neural tube. The ventricles of the adult brain develop from this cavity.

Some cells in the neural tube are called spongioblasts; glial cells develop from these. Others, known as neuroblasts, give rise to adult neurons. Some cells in the neural crest develop into the unipolar cells of the spinal ganglia, others into neurilemmal cells, and still others, together with neuroblasts from the basal plate, migrate to positions alongside the vertebral column and to viscera. Most of these migrating cells develop into multipolar neurons of the autonomic ganglia. Some, however, give rise to the medullary cells of the adrenal glands. Cell division in the nervous system stops at or shortly after birth. Individual cells and processes, how-

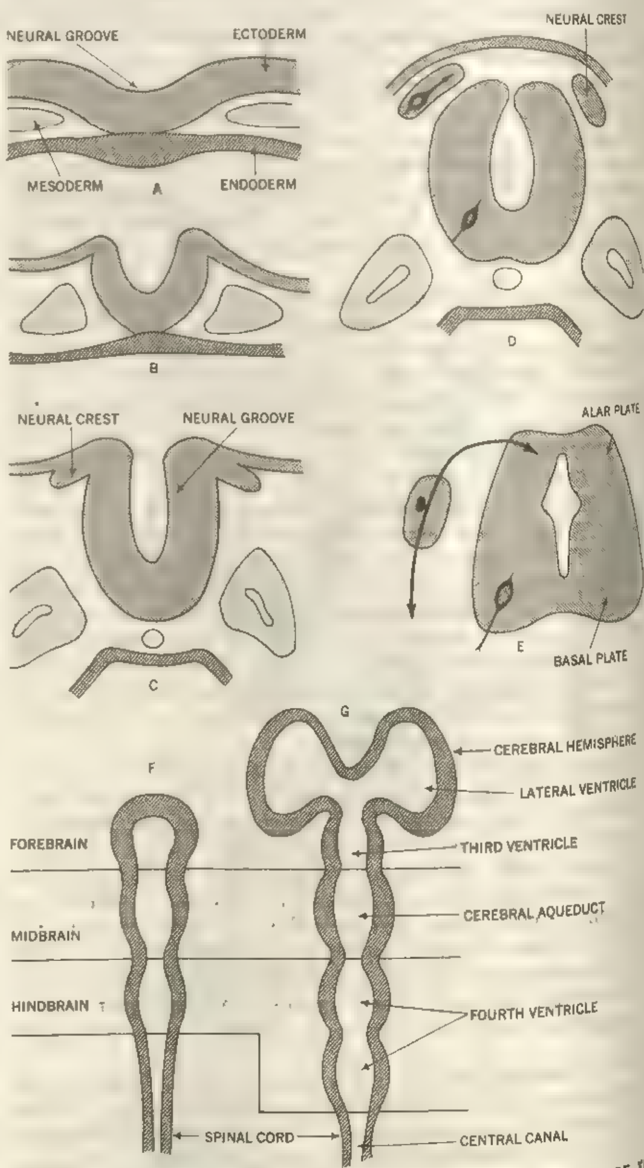

FIG. 3.—DIAGRAMMATIC REPRESENTATION OF CERTAIN FEATURES OF THE EMBRYOLOGY OF THE NERVOUS SYSTEM

(A–E) Cross-sections of parts of embryos. The ectoderm is a sheet of cells (individual cells not shown) that grows to form a longitudinal groove. The groove deepens and closes off to form a neural tube, from which the neural crest detaches. A single neuroblast is shown in the neural crest of D, and in E this has become a unipolar cell with processes growing centrally and peripherally. A neuroblast of the basal plate in D develops an axon that in E is growing out of the spinal cord. (F–G) Longitudinal views of the front end of the neural tube showing enlargements and cavities from which the adult brain develops

ever, continue to grow and enlarge until after adolescence.

COMPARATIVE ANATOMY

The nervous systems of vertebrates have certain features in common and show certain evolutionary changes that are summarized very briefly here.

The vertebrates include fishes, amphibians, reptiles, birds and mammals and are the largest subdivision (subphylum) of the phylum Chordata. All chordates have a single nerve trunk situated along the back, above the notochord or the vertebrae. This cord is a hollow, nonganglionated structure with a central, fluid-filled cavity. Its embryonic development is similar in all chordates. The anterior (front) end of this tube has evolved, in vertebrates, into a hollow brain with characteristic subdivisions. There are also characteristic sense organs (eyes, ears, etc.) that develop in the head region of vertebrates. The rest of the tube becomes the spinal cord.

The spinal cord has nerve roots attached to it. In *Amphioxus* (the lancelet; not a vertebrate, but a primitive chordate) the dorsal and ventral roots alternate; a dorsal root on one side is opposite a ventral root on the other. The dorsal roots are both sensory and motor; the ventral roots are purely motor. In fishes and higher vertebrates, dorsal and ventral roots unite to form spinal nerves, and there is an increasing tendency for dorsal roots to be entirely sensory. Ventral roots are motor in all chordates.

The cranial nerves of chordates are special nerves associated with the brain. They are named from studies in man, but the human arrangement of 12 pairs does not hold throughout the phylum Chordata. In *Amphioxus*, for example, there are two pairs of cranial nerves. The 12th pair of cranial nerves (hypoglossal) is absent in fishes. The 11th pair (accessory) is not separate in lower vertebrates, but is part of the 10th pair (vagus). The first pair in most vertebrates is the "terminal nerve"; it is absent or rudimentary in man.

The fibres in cranial nerves are of several types. Some cranial nerves are composed of but one type, others of several. There are fibres for the special senses, general sensory fibres from the head and face, special sensory and motor fibres for the branchial or gill region (primarily pharynx, larynx, facial muscles, muscles of mastication), parasympathetic fibres and motor fibres to eye muscles and tongue.

The major evolutionary changes of the nervous system are found in the brain. The hind end of the brain stem (the brain stem connects the cerebral hemispheres with the spinal cord) contains motor and sensory nerve cells like those of the spinal cord. It also contains groups of nerve cells concerned with certain special sensations, such as hearing, balance and taste, and with certain vital functions, such as respiration and circulation. This part of the brain stem changes relatively little in ascending the vertebrate scale.

The cerebellum is a part of the brain that is concerned with automatic regulation of posture and movement. Certain groups of cerebellar neurons regulate trunk muscles, others limb muscles, and still others are connected with the cerebral cortex. Hence the anatomical arrangement of the cerebellum varies greatly from species to species, depending on mode of locomotion. The cerebellum is relatively best developed in primates, especially in man.

In lower vertebrates, the main nervous centres are in the front end of the brain stem, which receives impulses of the special and general sensations. It acts as a co-ordinating centre. Parts of it are highly developed in birds, in which those portions devoted to vision are relatively large.

The primitive cerebral hemispheres are centres for smell, but in higher vertebrates they carry out many of the functions of the brain stem. Furthermore, by virtue of a complex surface layer of nerve cells, the cerebral cortex, the hemispheres in higher vertebrates are important association centres. The increasing importance and complexity of the cerebral hemispheres are associated with two main evolutionary trends. One involves the cerebral cortex, which is first present in reptiles and is most highly developed in man (important regions of the human cerebral cortex are concerned with speech mechanisms). The other trend involves the basal ganglia.

Basal ganglia are masses of nerve cells in the interior of the cerebral hemispheres and are concerned with many stereotyped or automatic aspects of movement, sensation, visceral activity and emotional behaviour. Basal ganglia are first present in amphibians and are most specialized and advanced in birds, in which they are the highest level of nervous function. Basal ganglia are present and important in mammals, but are overshadowed by the increasing development and complexity of the cerebral cortex.

AUTONOMIC NERVOUS SYSTEM

The term autonomic nervous system refers to those parts of the central and peripheral nervous systems that regulate the activity of the viscera. By a very broad definition the term viscera means the heart with its special type of muscle, and any organ or structure, such as stomach or skin, that contains smooth (involuntary) muscle and glands. The term autonomic implies an autonomy that does not actually exist. For example, skin exposed to cold air becomes blanched or pale because of a reflex constriction of blood vessels in the skin. The cold air stimulates temperature receptors in the skin, and the spinal reflex, by way of autonomic fibres to blood vessels, acts to conserve heat. At the same time impulses are sent to the brain for the sensation of cold. This is an example of co-ordination of somatic and autonomic activities.

The autonomic nervous system can be considered as a series of levels that differ in function in that the higher the level the more widespread and general its functions; the lower the level the more restricted and specific the functions. The highest level is the cerebral cortex, certain areas of which control or regulate all visceral functions. These areas send nerve fibres to the next level, the hypothalamus, at the base of the brain. The hypothalamus is a co-ordinating centre for the motor control of visceral activity. One of its many functions, for example, is regulation of body temperature. The hypothalamus has nervous and vascular connections with the pituitary gland, by virtue of which it influences the pituitary and through it the entire endocrine system. The hypothalamus also sends nerve fibres to lower centres in the brain stem that are concerned with still more specific functions; *e.g.*, the reflex regulation of respiration, heart rate and circulation. These centres function by virtue of their connections with still lower centres, which are collections of nerve cells that send their axons into certain cranial and spinal nerves. It is characteristic of these axons that, unlike motor fibres to skeletal muscle, they synapse with multipolar cells outside the central nervous system before they reach the viscus to be supplied. These cells are collected into ganglia; hence the ganglionic level is the lowest one. The axons from the central nervous system to ganglion cells are termed preganglionic fibres. The axons of ganglion cells are called postganglionic fibres, and all such fibres from a particular ganglion supply a specific organ or region of the body.

The preganglionic fibres that issue from the thoracic and upper lumbar levels of the spinal cord comprise the sympathetic or thoracolumbar part of the autonomic system. These fibres reach spinal nerves by way of ventral roots, then leave the spinal nerves to enter adjacent ganglia (fig. 4). These ganglia are contained in long nerve trunks (sympathetic trunks), one on each side of the vertebral column, extending from the base of the skull to the coccyx. Some preganglionic fibres continue to medullary cells of the suprarenal glands, but most synapse in the ganglia. The postganglionic fibres either go directly to adjacent viscera and blood vessels, or else return to spinal nerves and thus reach blood vessels, smooth muscle and glands of the limbs and body wall.

The preganglionic fibres that issue from the brain stem and sacral part of the spinal cord comprise the parasympathetic or craniosacral part of the autonomic system. The ganglion cells with which these fibres synapse are in or near the organs innervated. The postganglionic fibres are very short; apparently none go to the blood vessels, smooth muscle and glands of the limbs and body wall. Most viscera have a double motor supply, sympathetic and parasympathetic, generally with opposing functions.

There is also a physiological classification. Certain chemicals

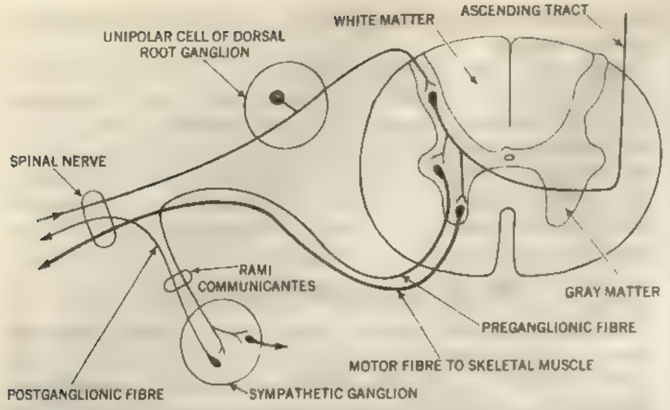

FIG. 4.—DIAGRAM OF REFLEX PATHS IN THORACIC (SYMPATHETIC) PORTION OF AUTONOMIC SYSTEM

A sensory fibre enters the spinal cord (shown in cross section) over a dorsal root and synapses with a cell, the axon of which synapses with motor cells, then ascends to the brain. Motor fibres leave by way of a ventral root. Preganglionic sympathetic fibre leaves the spinal nerve to synapse in a ganglion of the sympathetic trunk. Postganglionic fibres go to adjacent viscera or back to the spinal nerve

that are liberated at the terminals of postganglionic autonomic fibres act as transmitters; *i.e.*, they are released when nerve impulses arrive, and in turn they initiate activity in the viscus or alter its existing activity. Acetylcholine is liberated at postganglionic parasympathetic terminals; such fibres are called cholinergic. Noradrenaline is released at most postganglionic sympathetic terminals, and such fibres are called adrenergic. The sympathetic fibres to smooth muscle and sweat glands of the skin, however, are cholinergic. Adrenaline, formed by the medullary cells of the adrenal glands and released into the blood stream, has actions similar to those of noradrenaline. Hence the sympathetic system, by virtue of stimulating the release of adrenaline, can enhance its own actions.

The autonomic system is an important part of the mechanism by which the body keeps its internal environment constant; *i.e.*, maintains temperature, fluid balance, ionic composition of the blood, etc. This maintenance is generally known as homeostasis. The parasympathetic system regulates many specific functions, such as digestion, intermediary metabolism and excretion. The sympathetic system is an important part of the mechanism by which a person reacts to stress. This system tends to act as a whole, especially when stress is of sudden onset. For example, a situation that results in fear or rage may also result in increased blood pressure, pulse rate, cardiac output and blood sugar, measures designed for "fight or flight." These acute responses to stress are widespread because the sympathetic system has many connections and also because adrenaline is secondarily released into the blood stream.

Stress may also be followed by more slowly developing changes in metabolic activities and defense mechanisms, brought about by activation of the hypothalamic–pituitary system, leading to changes in the functions of the endocrine organs.

NERVOUS SYSTEM, DISEASES OF. It is convenient to consider diseases of the nervous system according to their effects on three parts of that system—the brain, the spinal cord and the peripheral (sensory and motor) nerves. (For information on the anatomy and physiology of the nervous system the reader should consult BRAIN; MENINGES AND CEREBROSPINAL FLUID; NERVE; NERVE CONDUCTION; NERVOUS SYSTEM; PARALYSIS; SPINAL CORD; TIC. Other articles relating to diseases of the nervous system, in addition to those cited as cross references later in this article, include CEREBRAL PALSY; DEMENTIA; DRUG ADDICTION; HEADACHE; HYDROCEPHALUS; METABOLISM, DISEASES OF; NERVOUS SYSTEM, SURGERY OF; NEURALGIA; NEUROPHARMACOLOGY AND PSYCHOPHARMACOLOGY; NEUROSES; PSYCHIATRY; PSYCHOSES; SPINE, DISEASES AND DISABILITIES OF; STROKE; VERTIGO AND DIZZINESS.)

The disease processes affecting the brain, spinal cord and peripheral nerves are in general similar, but the resulting symptoms and signs may be distinctive in each part. Diseases may attack each part separately, or two or all three together. These three parts subserve sensation and voluntary movement. There is, in addition, a partly segregated autonomic or vegetative nervous system that controls the viscera, blood vessels and the secretion of certain glands. This system is connected with the brain and spinal cord centrally and its fibres also join in the distribution of peripheral nerves, but part of it is anatomically separated and is disposed as a series of nerves and ganglia along each side of the spinal canal; here local disease may attack the autonomic system alone or part of it. In diagnosis, both the nature of the disease process and where it attacks must be considered.

The main categories of diseases affecting the nervous system are: congenital disease, when the individual is born with some inherent defect; inflammatory and infective, when bacteria, viruses or other germs infect the nervous system; toxic and metabolic, when a poison, either from outside or as a result of some abnormal metabolism of the body, acts on the nervous system; deficiency, when some essential food factor is absent from the diet; traumatic, when injury causes defect; neoplastic, when a new growth or tumour damages the system; vascular, when the blood vessels supplying essential nutriment to the system are diseased; and degenerative, when the cells or nerve fibres of the nervous system show intrinsic degeneration. Congenital diseases usually show themselves in infancy. Inflammatory, infective, toxic and metabolic troubles may occur in any age group. This also applies to trauma, though exposure to this may be greater during the physically active years of early adult life. Neoplasms are commoner in middle and late life. Vascular and degenerative diseases are more frequent in the elderly.

Peripheral Nerve Disease.—If peripheral nerves are diseased, those parts of the body that they supply suffer a loss of power and sensation. There may also be local changes in blood supply and sweating because the autonomic nerve fibres are carried by peripheral nerves.

Individual peripheral nerves are commonly affected by injury causing a localized traumatic neuropathy. As pressure is a ready source of injury, the nerves most susceptible to this type of injury are those that at some part of their course lie near the surface of the body and in relation to bone, so that compression can easily occur. Nerves often affected by traumatic neuropathy are the ulnar nerve at the elbow, the median nerve as it passes under the firm carpal ligament to enter the palm of the hand, the radial nerve as it winds round the shaft of the humerus, and the lateral popliteal nerve as it winds round the head of the fibula.

Generalized affections of peripheral nerves (*polyneuritis*), when weakness, numbness and tingling at the periphery of limbs occur, are usually toxic or metabolic in origin. External poisons that may cause polyneuritis include arsenic, lead and mercury and a number of organic compounds, some of which may be used as drugs. There is individual variation in the response to these agents and some people develop neuropathy more easily than others. Alcohol can produce a polyneuritis by interfering with the nervous normal supply of thiamine (vitamin B_1). Supplying extra thiamine will sometimes dramatically reverse this type of polyneuritis. Nutritional deficiency, both of thiamine and of another vitamin (B_{12}, also called cyanocobalamin, or cobalamine), may, of itself, also produce a polyneuritis. So may the endogenous toxic metabolic upset associated with diabetes (*see* DIABETES MELLITUS

LITUS: *Signs and Symptoms*); less often it may cause a localized neuropathy of one or more nerves (*mononeuritis multiplex*). In the 1950s it was discovered that carcinoma, especially of the lung, may sometimes cause a generalized polyneuritis. When the small arteries supplying blood to nerves are diseased, as in the condition of *polyarteritis nodosa*, polyneuritis may also result, usually producing both motor and sensory symptoms, though one or the other may occasionally predominate or appear alone.

Peripheral nerves originate as sensory and motor nerve roots from the spinal cord, several roots or parts of them combining to form a given nerve. Disease may attack the nerve roots and cause pain in the distribution of the root, as well as sensory and motor loss. Such lesions are usually traumatic from pressure by nearby structures, since the roots run for a short distance inside the bony spinal canal where pressure occurs from diseased vertebrae or intervertebral cartilaginous discs. In the upper limb a form of arthritis of the neck (*cervical spondylosis*), in which disc and bony changes occur, may cause cervical nerve root lesions leading to brachial neuropathy and sometimes pressure on the spinal cord as well. In the lower limbs, a similar pathology of intervertebral discs causes *sciatica* (*see* NEURITIS) and *lumbago*.

Spinal Cord Disease.—The spinal cord consists mainly of nerve tracts carrying impulses for sensation up to the brain and for movement down to peripheral nerves and muscles. If it is diseased there is loss of power, sensation, visceral control and autonomic function below the level of the disease. This is usually a generalized change but may sometimes be mainly on one side of the body in unilateral cord disease. In such cases motor function may be largely affected on one side and sensory on the opposite, since sensory nerve fibres conducting pain and heat sensation cross immediately after entering the spinal cord, while motor fibres travel up on the side they enter until they reach the brain stem. Occasionally disease may be limited to a small part of the cord so that only certain functions, motor or sensory, are altered and the spinal cord tracts as a whole are not interrupted. In this case, motor or sensory function will be affected only in the body areas supplied by the diseased segment of cord and there may be no general loss of function below the lesion. Sometimes, also, tracts serving one function (motor, sensory or connected with the cerebellum and co-ordination) seem to be selectively diseased, producing disability limited to a function rather than to an anatomical area. As with peripheral nerves, autonomic function may also be affected in cord disease.

As the spinal cord is contained in a rigid bony canal, it is readily compressed by anything that causes enlargement of the surrounding vertebrae or of the contents of the canal. Thus inflammation or tumour of the spinal bones may cause pressure on the cord with consequent interruption of sensory and motor function below the level of the compression. This not only produces weakness, numbness and possibly paresthesia in limbs and trunk below the lesion but also interferes with control of bladder and bowel function. *Spinal caries* (tuberculosis of the vertebrae) used to be a common cause of this but has decreased with the lessened frequency of tuberculous infection. If an intervertebral disc becomes displaced it may sometimes press backward on the cord and produce compression, though it more usually causes pressure on nerve roots because the displacement is more commonly at the lateral edges rather than the central part of the disc.

The meninges, or membranes, that ensheath the spinal cord may also be the seat of disease that causes secondary defects of the cord. A tumour (*meningioma*) may cause pressure on the cord and inflammation (*meningitis*; *q.v.*) may pass directly to the cord or cause constriction and interference with its blood supply. It is probable that anything that causes constriction of the cord, whether by enlargement from within or pressure from without, causes some degree of vascular insufficiency, which of itself may result in damage or even total destruction of part of the cord. This is occasionally seen as a result of acute trauma when the anterior spinal artery is suddenly occluded and severe permanent damage to a segment of the cord results. Similar secondary vascular effects may occur when the cord is much swollen from inflammation, in virus infection for instance; these vascular disturbances may cause a necrotizing myelitis that is far more severe than the original inflammation. Intrinsic tumours of the cord (*gliomas*) are less common. They usually produce insidious signs of cord dysfunction at and below their site of origin. (*See* also TUMOUR.)

Virus diseases may attack the cord, a common one being *anterior poliomyelitis* (*see* POLIOMYELITIS), which affects mainly the motor nerve cells of the cord—the so-called anterior horn cells. The result is local weakness or loss of power, usually of segmental distribution of muscles to correspond with the cord segments most severely affected. There is no sensory change. *Herpes zoster* virus, on the other hand (*see* SKIN, DISEASES OF), is mainly sensory in incidence and attacks the posterior horn cells. Both these cause limited damage but other viruses seem to produce a general myelitis with inflammation affecting the whole thickness of the cord and its sensory and motor tracts.

Subacute combined degeneration affects both motor and sensory tracts in the cord and also causes a peripheral neuritis. It is associated with pernicious anemia (*see* ANEMIA: *Anatomical Derangements of Bone Marrow*) and is now known to be due specifically to vitamin B_{12} deficiency. If diagnosed early enough, it can be rapidly cured by treatment with vitamin B_{12}.
